An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page 1519.

One Gm. of Sodium Cacodylate shows no more *chloride* than corresponds to 0.3 cc. of fiftieth-normal hydrochloric acid.

The addition of 5 drops of barium chloride T.S. to 10 cc. of an aqueous solution of the salt (1 in 50), acidulated with 2 drops of hydrochloric acid, produces no turbidity within one-half minute (*sulphate*).

Assay—Dissolve about 2.5 Gm. of Sodium Cacodylate, accurately weighed, in 30 cc. of distilled water, render the solution neutral to phenolphthalein T.S. if necessary, and then titrate with normal hydrochloric acid, using methyl orange T.S. as indicator. Each cc. of normal hydrochloric acid corresponds to 0.16002 Gm. of $Na(CH_3)_2AsO_2$.

This assay is explained on page 1459.

Preserve in well-closed containers.

N. F. Preparation—Ampullæ Sodii Cacodylatis.

Uses—Its action is similar to other arsenic compounds but claimed to be less likely to produce poisoning because of its slow absorption in the body. Used in anemia and also in syphilis; usually administered hypodermically, in doses of one to three grains (0.065 to 0.2 Gm.).

SODII CARBONAS MONOHYDRATUS. U. S. Monohydrated Sodium Carbonate

[Sod. Carb. Monohyd.]

Monohydrated Sodium Carbonate, when rendered anhydrous by gentle ignition, contains not less than 99.5 per cent of Na_2CO_3 (124.02).

Preparation—Impure sodium carbonate, or soda-ash, is consumed in enormous quantities in the arts, and cheap methods of production have been long sought for. The process elaborated by Leblanc, a French apothecary, in 1784, has been most largely used, and it possesses an historic interest because of the public endorsements which it received from the French Government in 1794. It is remarkable that this process has been successfully worked, without material modifications, for a century, and has supplied the world with cheap soap and cheap glass. Notwithstanding this great service, Leblanc died a pauper in a French asylum, due to his process having been seized by the Government during the Reign of Terror, without return or credit to the inventor. Although the process is being superseded by other methods, it is

worthy of study, and is as follows: Sodium carbonate is made from common salt by two steps, first, by converting the salt by sulphuric acid into sodium sulphate, and, secondly, by decomposing the sulphate by calcium carbonate (lime stone) and charcoal (coal) at a high temperature, so as to yield sodium carbonate. The chemical reactions are as follows:

$$\underset{\text{sodium chloride}}{2NaCl} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{sodium sulphate}}{NaSO_4} + \underset{\text{hydrochloric acid}}{2HCl}$$

$$\underset{\text{sodium sulphate}}{Na_2SO_4} + \underset{\text{calcium carbonate}}{CaCO_3} + \underset{\text{carbon}}{C_4} = \underset{\text{sodium carbonate}}{Na_2CO_3} + \underset{\text{calcium sulphide}}{CaS} + \underset{\text{carbon monoxide}}{4CO}$$

The Solvay process for making sodium bicarbonate is given on page 621; the bicarbonate is easily converted into carbonate by heating, and the carbon dioxide is utilized in another part of the process.

$$\underset{\text{sodium bicarbonate}}{2NaHCO_3} = \underset{\text{sodium carbonate}}{Na_2CO_3} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{water}}{H_2O}$$

The cryolite process was formerly used largely in the United States. Cryolite, Al_2F_6+6NaF, consists mainly of a double fluoride of aluminum and sodium, containing, in 100 parts, 13 of aluminum, 34 of sodium, and 53 of fluorine. Sodium carbonate is obtained by heating cryolite with chalk, whereby calcium fluoride is formed, while the sodium and aluminum combine to form sodium aluminate, a weak salt, which is dissolved out by lixiviation. The soda is converted into carbonate by passing carbon dioxide under pressure through the solution; and the alumina, separated from the soda, becomes insoluble, and is deposited.

$$\underset{\text{cryolite}}{(Al_2F_6 + 6NaF)} + \underset{\text{calcium carbonate}}{6CaCO_3} = \underset{\text{sodium aluminate}}{Al_2O_3.3Na_2O} + \underset{\text{calcium fluoride}}{6CaF_2} + \underset{\text{carbon dioxide}}{6CO_2}$$

The second step in the reaction is as follows:

$$\underset{\text{sodium aluminate}}{Al_2O_3.3Na_2O} + \underset{\text{carbon dioxide}}{3CO_2} = \underset{\text{sodium carbonate}}{3Na_2CO_3} + \underset{\text{aluminum oxide}}{Al_2O_3}$$

Monohydrated sodium carbonate was first introduced into the U. S. P. VIII, because it is permanent in both moist and dry atmospheres and is also free from the large amount of water of crystallization found in *sal soda* or ordinary sodium carbonate (63 per cent), which is the cause of the rapid efflorescence in this latter compound in a dry atmosphere. This fact makes the crystal salt inconvenient to use in manufacturing since its strength is indefinite and it must be previously dried and the amount of anhydrous sodium carbonate determined before knowing the amount to use.

The monohydrated form is made by crystallizing a concentrated solution of sodium carbonate at a temperature above 35° C. (95° F.), and stirring the liquid so as to produce small crystals. It contains about 15 per cent of water of crystallization and replaces not only the deka-hydrate (sal soda) but also the exsiccated sodium carbonate of earlier pharmacopœias, which always varied in its water content, being very hygroscopic.

Sodium carbonate is also prepared by the electrolysis of sodium chloride, whereby sodium and chlorine are produced, the former reacting with water to produce sodium hydroxide and this solution treated with carbon dioxide to produce sodium carbonate.

Description and Physical Properties—A white, odorless, crystalline, granular powder. When exposed to the air under ordinary conditions it absorbs only a slight percentage of moisture. When exposed to warm, dry air at or above 50° C., the salt effloresces, and at 100° C. becomes anhydrous.

One Gm. of Monohydrated Sodium Carbonate is soluble in 3 cc. of water, and in 7 cc. of glycerin, at 25° C. One Gm. is soluble in 1.8 cc. of boiling water. It is insoluble in alcohol.

Tests for Identity—An aqueous solution of Monohydrated Sodium Carbonate (1 in 10) is strongly alkaline to litmus paper and to phenolphthalein T.S. and responds to the reactions for sodium (page 617), and for carbonates (page 589).

Tests for Purity—An aqueous solution of Monohydrated Sodium Carbonate (1 in 50), mixed with a slight excess of hydrochloric acid, meets the requirements of the test for *heavy metals*, page 1519.

Weigh accurately about 2 Gm. of Monohydrated Sodium Carbonate and heat it in a crucible at 110° C. to constant weight: the loss is not less than 10 per cent and not more than 15 per cent (*water*).

Assay—Transfer the anhydrous sodium carbonate obtained in the foregoing test to a flask with the aid of 50 cc. of distilled water and titrate with normal sulphuric acid, methyl orange T.S. being used as indicator. Each cc. of normal sulphuric acid corresponds to 0.05301 Gm. of Na_2CO_3.

This assay is explained on page 1455.

Preserve in well-closed containers.

U. S. P. Preparations—Liquor Sodæ Chlorinatæ; Massa Ferri Carbonatis; Suppositoria Glycerini.

N. F. Preparations—Ferri Oxidum Saccharatum; Linimentum Saponato-Camphoratum; Sal Carolinum Factitium.

Uses—Monohydrated sodium carbonate is one of the most useful of the alkaline salts; it is the source of most of the sodium salts made by the pharmacist. It is rarely given internally. The dose is from two to ten grains (0.13 to 0.65 Gm.).

SODII CHLORIDUM. U. S. Sodium Chloride
[Sod. Chlorid.]

Sodium Chloride, when dried to constant weight at 110° C., contains not less than 99 per cent of NaCl (58.46).

Preparation—Common salt is universally distributed over the world, and may be mined, as rock salt, by evaporating the purified solution of saline deposits, or by evaporating sea water, and afterwards purifying. If perfectly free from contaminating salts, it is not hygroscopic.

Description and Physical Properties—Colorless, odorless, transparent, cubical crystals, or a white, crystalline powder. It is usually slightly hygroscopic.

One Gm. of Sodium Chloride is soluble in 2.8 cc. of water, and in 10 cc. of glycerin, at 25° C. One Gm. is soluble in 2.7 cc. of boiling water. It is slightly soluble in alcohol.

Tests for Identity—When heated somewhat above 100° C., the salt decrepitates. At higher temperatures it fuses, and is slowly volatilized and partly decomposed.

An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, page 617, and for chlorides, page 567.

Tests for Purity—An aqueous solution of Sodium Chloride (1 in 10) is neutral to litmus paper.

An aqueous solution of Sodium Chloride meets the requirements of the test for *heavy metals*, page 1519.

Separate portions of 10 cc. each of an aqueous solution of Sodium Chloride (1 in 100) after the addition of 1 cc. of ammonia T.S. shows no immediate turbidity upon the addition of ammonium oxalate T.S. (*calcium*), or of sodium phosphate T.S. (*magnesium*).

Digest 2 Gm. of the finely powdered salt for three hours with 25 cc. of warm alcohol, cool the mixture and remove the undissolved salt by filtration. Evaporate the filtrate to dryness, dissolve the residue in 5 cc. of distilled water, add 1 cc. of chloroform, and cautiously introduce, drop by drop, with constant agitation, chlorine T.S. which has been diluted with twice its volume of distilled water: the chloroform does not acquire a violet, yellow, or orange color (*iodide or bromide*).

Assay—Proceed as directed under the assay for chlorides, page 1514, using about 0.25 Gm. of Sodium Chloride, dried to constant weight at 110° C. and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.005846 Gm. of NaCl.

This assay is explained on page 1463.

Preserve in well-closed containers.

U. S. P. Preparation—Liquor Sodii Chloridi Physiologicus.

N. F. Preparations—Liquor Pancreatini; Liquor Procainæ Hydrochloridi; Lotio Ammoniacalis Camphorata; Sal Carolinum Factitium; Sal Kissingense Factitium; Sal Vichyanum Factitium.

Uses—Sodium chloride is largely used as a condiment. Most commercial varieties of table salt are unfit for use in pharmacy as they contain foreign substances added to diminish their hygroscopic quantity. It undoubtedly serves a useful purpose in the animal economy, as many animals possess an instinctive craving for it. Salt baths are tonic, and valuable aids in many diseases. It is largely used in surgery in what is commonly called "normal salt solution" (see below). Common salt is used as a styptic in hemorrhage and as an antiseptic.

Average dose—4 drachms (16 Gm.).

LIQUOR SODII CHLORIDI PHYSIOLOGICUS. U. S. Physiological Solution of Sodium Chloride

The formula for this solution, commonly known as *Normal Salt Solution*, is given in the chapter on Sterilization, where it is also discussed.

SODII CITRAS. U. S. Sodium Citrate [Sod. Cit.]

Sodium Citrate contains not less than 98 per cent of $Na_3C_6H_5O_7.2H_2O$ (294.10).

Preparation—This salt is usually prepared by adding sodium carbonate to a solution of citric acid until effervescence ceases, evaporating and granulating the product. It is also prepared by treating sodium sulphate solution with calcium citrate, filtering, concentrating, and crystallizing the product.

Description and Physical Properties—Small crystals, or a white, granular powder. It is odorless and has a cooling, saline taste.

One Gm. of Sodium Citrate is soluble in 1.3 cc. of water at 25° C. and in 0.6 cc. of boiling water. It is insoluble in alcohol.

Tests for Identity—When heated to about 150° C., the salt loses all of its water of crystallization; on ignition at a red heat, it carbonizes and emits inflammable gases which have a very pungent, acrid odor, and a residue remains which is alkaline to litmus paper and strongly effervesces with acids.

An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, page 617, and for citrates, page 944.

Tests for Purity—An aqueous solution of Sodium Citrate (1 in 20) is slightly alkaline to litmus paper, but is not reddened by 1 drop of phenolphthalein T.S.

To a solution of 1 Gm. of Sodium Citrate in 2 cc. of distilled water, add 1 cc. of potassium acetate T.S. and 1 cc. of acetic acid: no crystalline precipitate forms (*tartrate*).

An aqueous solution of Sodium Citrate meets the requirements of the test for *heavy metals*, page 1519.

An aqueous solution of the salt meets the requirements of the test for *arsenic*, page 1512.

Assay—Proceed as directed under the assay for alkali salts of organic acids, page 1514. Each cc. of half-normal sulphuric acid corresponds to 0.04902 Gm. of $Na_3C_6H_5O_7.2H_2O$.

This assay is explained on page 1456.

Preserve in well-closed containers.

U. S. P. Preparations—Glyceritum Acidi Tannici; Glyceritum Phenolis.

N. F. Preparations—Elixir Gentianæ, Liquor Peptonati; Liquor Phosphatum Compositus; Syrupus Hypophosphitum Compositus; Tinctura Ferri Citro-Chloridi.

Uses—Sodium citrate is preferred to potassium citrate by some practitioners, and it is used in making compound syrup of hypophosphites and other preparations containing salts of iron and manganese, these being rendered more soluble in the presence of an alkaline citrate or tartrate. It is also an important ingredient in Tincture of Ferric Citro-Chloride, its presence in iron solutions lessening the tendency to darken when iron is added to tannins. This is illustrated in the Elixir of Gentian and Iron where its presence makes it unnecessary to use a detannated gentian. The dose is four to fifteen grains (0.25 to 1 Gm.).

SODII IODIDUM. U. S. Sodium Iodide
[Sod. Iod.]

Sodium Iodide, when dried to constant weight at 120° C., contains not less than 99 per cent of NaI (149.92). It contains not more than 7 per cent of water.

Preparation—This iodide may be prepared by double decomposition between solutions of ferroso-ferric iodide and sodium carbonate, or by treating a solution of sodium hydroxide with iodine, exactly as in the preparation of potassium iodide. The former process is preferable if working on a small scale.

$$\underset{\text{ferroso-ferric iodide}}{Fe_3I_8} + \underset{\text{sodium carbonate}}{4Na_2CO_3} = \underset{\text{sodium iodide}}{8NaI} + \underset{\text{ferroso-ferric oxide}}{Fe_3O_4} + \underset{\text{carbon dioxide}}{4CO_2}$$

By boiling the solution containing the ferrous carbonate, the latter is rendered less bulky, and it can be easily separated by filtration.

Description and Physical Properties—Colorless, odorless, cubical crystals, or a white, crystalline powder. In moist air Sodium Iodide deliquesces, or at first cakes and then deliquesces, and frequently undergoes decomposition, assuming a brown tint.

One Gm. of Sodium Iodide is soluble in 0.55 cc. of water, in about 2 cc. of alcohol, and in 1 cc. of glycerin, at 25° C. One Gm. is soluble in 0.4 cc. of boiling water.

When heated to about 660° C., Sodium Iodide melts, and at higher temperatures it is slowly volatilized and partly decomposed.

Test for Identity—An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, page 617, and for iodides, page 575.

Tests for Purity—Dissolve 1 Gm. of Sodium Iodide in 10 cc. of distilled water, and add 0.15 cc. of tenth-normal sulphuric acid: no red color is produced by the addition of a drop of phenolphthalein T.S. (*alkali*).

A solution of 1 Gm. of the salt in 2 cc. of distilled water yields no precipitate with 1 cc. of sodium bitartrate T.S. (*potassium*).

Dissolve 0.5 Gm. of the salt in 10 cc. of distilled water which has been previously boiled and cooled, and add 2 drops of diluted sulphuric acid: no distinct, yellow color appears within half a minute (*iodate*), and no turbidity occurs (*thiosulphate*).

Add 5 cc. of sodium hydroxide T.S. and about 0.2 Gm. of aluminum wire to a solution of 1 Gm. of Sodium Iodide in 5 cc. of distilled water contained in a test tube of about 40 cc. capacity. Insert a pledget of purified cotton in the upper portion of the test tube, and place a piece of moistened red litmus paper over its mouth. On heating the tube and contents on a water bath for fifteen minutes, no blue coloration of the paper is discernible (*nitrate or nitrite*).

A 10 cc. portion of an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is not rendered turbid by the addition of 1 cc. of potassium sulphate T.S. (*barium*).

A 2 Gm. portion of Sodium Iodide shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid, page 1567.

Heat gently 5 cc. of an aqueous solution of the salt (1 in 10) with 1 drop of ferrous sulphate T.S., 1 drop of ferric chloride T.S., and 0.5 cc. of sodium hydroxide T.S.: no blue color appears after acidulating the mixture with hydrochloric acid (*cyanide*).

An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page 1519.

Dry the salt to constant weight at 120° C.: the loss in weight does not exceed 7 per cent (*water*).

Assay—Proceed as directed under the assay for iodides, page 575, using about 0.5 Gm. of Sodium Iodide, previously dried to constant weight at 120° C. and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.01499 Gm. of NaI. Each Gm. of Sodium Iodide, previously dried, corresponds to not less than 66 cc. and not more than 67.7 cc. of tenth-normal silver nitrate.

This assay is explained on page 1462.

Preserve in well-closed containers.

N. F. Preparation—Elixir Euphorbiæ Compositus.

Uses—Medicinally, this salt is preferred to potassium iodide by some practitioners although, apparently, without good reason. The dose is from five to fifteen grains (0.32 to 1 Gm.).

SODII NITRIS. U. S. Sodium Nitrite
[Sod. Nitris]

Sodium Nitrite, when dried to constant weight over sulphuric acid, contains not less than 95 per cent of $NaNO_2$ (69.01).

Preparation—Sodium nitrite is made by heating sodium nitrate in contact with starch, or preferably by adding strips of sheet lead to sodium nitrate,

and heated to the fusing point for several hours, lead oxide being formed at the same time. After cooling, the fused sodium nitrite is lixiviated with water, purified, and recrystallized.

$$\underset{\text{sodium nitrate}}{NaNO_3} + \underset{\text{lead}}{Pb} = \underset{\text{sodium nitrite}}{NaNO_2} + \underset{\text{lead oxide}}{PbO}$$

Description and Physical Properties—White, or nearly white, opaque, fused masses or sticks; or colorless, transparent crystals; or a white or slightly yellow granular powder. It is odorless and has a mild saline taste. When exposed to the air, Sodium Nitrite deliquesces and is gradually oxidized to sodium nitrate, making it unfit for use.

One Gm. of Sodium Nitrite is soluble in 1.5 cc. of water at 25° C. It is sparingly soluble in alcohol, and is very soluble in boiling water.

When heated to about 270° C. the salt melts, and at a red heat it decomposes yielding oxygen, nitrogen, nitrous oxides, and sodium oxide.

Tests for Identity—An aqueous solution of the salt responds to the reactions for sodium, page 617, and for nitrites, page 551.

An aqueous solution of the salt (1 in 20) is slightly alkaline to litmus paper.

Tests for Purity—Dissolve 0.5 Gm. of Sodium Nitrite in 25 cc. of diluted hydrochloric acid, evaporate the solution to dryness, and dissolve the residue in 25 cc. of distilled water, adding a few drops of diluted hydrochloric acid: a 10 cc. portion of the resulting solution meets the requirements of the test for *heavy metals*, page 1519.

Assay—Dry about 1 Gm. of Sodium Nitrite to constant weight over sulphuric acid, weigh accurately in a stoppered weighing-bottle, dissolve the salt in a measuring flask with sufficient distilled water to make 100 cc., and add 10 cc. of this solution, from a pipette, to a mixture of 50 cc. of tenth-normal potassium permanganate, 100 cc. of distilled water, and 5 cc. of sulphuric acid. In adding the sodium nitrite solution, immerse the tip of the pipette beneath the surface of the permanganate mixture. Warm the liquid to 40° C., allow it to stand for five minutes, and then titrate with tenth-normal oxalic acid. Each cc. of tenth-normal potassium permanganate corresponds to 0.003451 Gm. of $NaNO_2$.

This assay is explained on page 1475.

Preserve in well-closed containers.

Uses—This salt is used in the manufacture of spirit of ethyl nitrite, although there is no longer an official process. The average dose is one grain (0.065 Gm.).

SODII PHOSPHAS. U. S. Sodium Phosphate
[Sod. Phos.]

Sodium Phosphate contains not less than 39.25 per cent and not more than 44.00 per cent of Na_2HPO_4 (142.05), corresponding to not less than 99 per cent of the crystallized salt [$Na_2HPO_4.12H_2O = 358.24$].

Preparation—The part of bones which is incombustible is obtained by burning them to whiteness, and consists of tribasic calcium phosphate called *bone-phosphate* or *bone-ash*, associated with some calcium carbonate. *Phosphorite*, the normal calcium phosphate occurring in nature, may also be used. When this is mixed with sulphuric acid, the calcium carbonate is entirely decomposed, giving rise to effervescence, should any carbonate be present. The calcium phosphate undergoes partial decomposition; part of the calcium precipitates as calcium sulphate, while the phosphoric acid remains in solution as an acid calcium phosphate (monobasic calcium phosphate), holding a small portion of calcium sulphate in solution.

$$\underset{\text{calcium phosphate}}{Ca_3(PO_4)_2} + \underset{\text{sulphuric acid}}{2H_2SO_4} = \underset{\text{acid calcium phosphate}}{CaH_4(PO_4)_2} + \underset{\text{calcium sulphate}}{2CaSO_4}$$

In order to separate the acid phosphate from the precipitated mass of calcium sulphate, boiling water is added to the mixture, the whole is strained, and the precipitate washed as long as acid phosphate is removed, which is determined by the water which passes through having an acid reaction. The different liquids are mixed and allowed to stand; upon cooling, a portion of calcium sul-

phate is deposited, which is removed by decantation. The bulk of the liquid is now concentrated by evaporation, and a fresh portion of calcium sulphate is deposited, which is separated by subsidence and decantation as before. The acid calcium phosphate solution, being heated, is now saturated by means of a hot solution of sodium carbonate. The carbonic acid is liberated with effervescence, and sodium phosphate is produced, while the acid calcium phosphate is converted into dibasic calcium phosphate and precipitates.

$$\underset{\text{primary calcium phosphate}}{CaH_4(PO_4)_2} + \underset{\text{sodium carbonate}}{Na_2CO_3} = \underset{\text{secondary calcium phosphate}}{CaHPO_4} + \underset{\text{sodium phosphate}}{Na_2HPO_4} + \underset{\text{water}}{H_2O} + \underset{\text{carbon dioxide}}{CO_2}$$

The calcium phosphate is separated by filtration, and the filtered liquid, which contains the sodium phosphate, is evaporated to the crystallizing point.

Description and Physical Properties—Large, colorless, odorless, monoclinic prisms, or a granular, crystalline salt. The crystals effloresce in the air.

One Gm. of Sodium Phosphate is soluble in 2.7 cc. of water at 25° C. It is very slightly soluble in alcohol.

When heated to about 40° C., the salt fuses, yielding a colorless liquid. At 100° C. it loses all of its water of crystallization, and at about 300° C. is converted into sodium pyrophosphate.

Tests for Identity—An aqueous solution of Sodium Phosphate (1 in 10) is alkaline to litmus paper and to phenolphthalein T.S.

An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, page 617, and for phosphates, page 586.

Tests for Purity—Dissolve 10 Gm. of Sodium Phosphate in 100 cc. of distilled water: not more than 0.02 Gm. of residue remains (*calcium or aluminum*).

No effervescence occurs on the addition of hydrochloric acid to a solution of the salt (*carbonate*).

One Gm. of Sodium Phosphate shows no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid, page 1556, and 0.2 Gm. shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid, page 1567.

An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page 1519.

An aqueous solution of the salt meets the requirements of the test for *arsenic*, page 1512.

Assay—Place about 0.4 Gm. of Sodium Phosphate, accurately weighed, in a 100 cc. graduated flask, dissolve it in 10 cc. of distilled water, add 50 cc. of tenth-normal silver nitrate, and thoroughly agitate the mixture. Gradually add reagent zinc oxide in small portions until the liquid is neutral to litmus paper. Then add distilled water to make 100 cc., agitate the mixture thoroughly, and filter through a filter which has not been previously moistened, rejecting the first 20 cc. of filtrate. Collect 50 cc. of the subsequent clear filtrate, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate to the production of a permanent red color. Each cc. of tenth-normal silver nitrate corresponds to 0.004735 Gm. of Na_2HPO_4.

This assay is explained on page 1463.

Preserve in well-closed containers.

U. S. P. Preparation—Sodii Phosphas Exsiccatus.

N. F. Preparation—Liquor Sodii Phosphatis Compositus.

Uses—Sodium phosphate is principally used as a cathartic; it must comply with the official requirements for purity and especially for freedom from arsenic. It may be given in doses of one drachm to half an ounce (4 to 16 Gm.).

SODII PHOSPHAS EFFERVESCENS. U. S. Effervescent Sodium Phosphate [Sod. Phos. Eff.]

	Metric	Alternative
Exsiccated Sodium Phosphate, in fine powder	200 Gm.	4 oz. av.
Sodium Bicarbonate, dried and powdered	477 Gm.	9 oz. av. 236 gr.
Tartaric Acid, dried and powdered	252 Gm.	5 oz. av. 18 gr.
Citric Acid, uneffloresced crystals	162 Gm.	3 oz. av. 105 gr.
To make	1000 Gm.	20 oz. av.

Powder the citric acid, and mix it intimately with the exsiccated sodium phosphate and tartaric acid, and then thoroughly incorporate the sodium bicarbonate.

Place the mixed powders on a plate of glass or in a suitable dish in an oven heated to between 93° and 104° C. Manipulate the mixture carefully with a

wooden spatula, and when it has become moist, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. Immediately transfer the salt to suitable containers and seal them tightly. Care must be taken to prevent the product from coming in contact with air which contains moisture.

An effervescent sodium phosphate, containing no citric or tartaric acid, is sold under the name *Sofos* and is recognized in the 1925 N. N. R. Dihydrogen sodium phosphate, official as sodium biphosphate, which is acid in reaction, is used to produce effervescence in solution through its reaction with the sodium bicarbonate contained in the mixture. It is manufactured by the General Chemical Company, New York City.

Uses—Effervescent Sodium Phosphate furnishes a pleasant means of administering sodium phosphate. Dose, two and one-half drachms (10 Gm.).

SODII PHOSPHAS EXSICCATUS. U. S. Exsiccated Sodium Phosphate
[Sod. Phos. Exsic.]

Exsiccated Sodium Phosphate, when dried to constant weight at 110° C., contains not less than 98 per cent of Na_2HPO_4 (142.05).

Sodium Phosphate, a convenient quantity.

Allow the crystals to effloresce for several days in warm air at a temperature of from 25° to 30° C., then continue the drying in an oven, raising the temperature very gradually until 110° C. has been reached. Maintain this temperature until the salt ceases to lose weight, powder and sift the residue, and transfer to well-closed containers.

Description and Physical Properties—A white powder which readily absorbs moisture. One Gm. of Exsiccated Sodium Phosphate is soluble in 8.1 cc. of water at 25° C., and in 1.1 cc. of boiling water. It is insoluble in alcohol.

Tests for Identity and Purity—Exsiccated Sodium Phosphate meets the requirements of the tests for identity, and, after allowance is made for the loss of water of crystallization, meets the requirements of the tests for purity under *Sodii Phosphas*.

Assay—Proceed as directed under *Sodii Phosphas*, using about 0.15 Gm. of the salt, previously dried to constant weight at 110° C. and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.004735 Gm. of Na_2HPO_4.

This assay is explained on page 1463.

Preserve in well-closed containers.

U. S. P. Preparations—Liquor Sodæ Chlorinatæ Chirurgicalis; Sodii Phosphas Effervescens.

Uses—This salt is used in making effervescent sodium phosphate, but should be freshly dried, as it otherwise will be variable in its water content, since it rapidly absorbs water if exposed to moist atmosphere, as much as 15 to 20 per cent often being present. It may be given in doses of from fifteen to thirty grains (1 to 2 Gm.). It is also used in preparing the official modified Dakin's solution (see page 570).

SODII BIPHOSPHAS. U. S. Sodium Biphosphate
[Sod. Biphos.—Sodium Dihydrogen Phosphate, Monosodium Orthophosphate]

Sodium Biphosphate, when dried to constant weight at 100° C., contains not less than 98 per cent of NaH_2PO_4. It contains not more than 15 per cent of water.

Sodium Biphosphate is prepared by boiling a solution of disodium phosphate with a calculated amount of nitric acid; or by adding phosphoric acid to a solution of the disodium salt until the liquid ceases to give a precipitate

with barium chloride. The latter method is illustrated by the following equation:

$$\underset{\text{disodium phosphate}}{Na_2HPO_4} + \underset{\text{phosphoric acid}}{H_3PO_4} = 2\underset{\text{monosodium phosphate}}{NaH_2PO_4}$$

The salt is then allowed to crystallize from the strong, hot solution.

Description and Physical Properties—Colorless, transparent crystals or a white, granular, crystalline powder. It is odorless and slightly deliquescent.

It is freely soluble in water and practically insoluble in alcohol, chloroform, and ether.

Tests for Identity—At 100° C. Sodium Biphosphate loses its water of crystallization (13.04 per cent); at 210° C. it is converted into disodium dihydrogen pyrophosphate ($Na_2H_2P_2O_7$). At still higher temperatures it is changed into a mixture of sodium metaphosphate ($NaPO_3$) and modifications of sodium metaphosphate.

An aqueous solution of Sodium Biphosphate is acid to litmus paper and produces effervescence with sodium carbonate.

An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, page 617, and for phosphates, page 586.

Tests for Purity—Dissolve 2 Gm. of Sodium Biphosphate in 40 cc. of distilled water, and add 1 drop of methyl orange T.S. If the solution is pink, it requires not more than 0.3 cc. of normal sodium hydroxide to discharge the pink color (*free acid*). If the solution is yellow, it requires not more than 0.3 cc. of normal sulphuric acid to render it pink (*disodium phosphate*).

An aqueous solution of the salt (1 in 10) does not become turbid when rendered slightly alkaline to litmus paper with ammonia T.S. (*aluminum, calcium*, etc.).

Dissolve 1 Gm. of the salt in 100 cc. of 1 per cent hydrochloric acid: a 10 cc. portion of this solution meets the requirements of the test for *heavy metals*, page 1519.

Dissolve 0.1 Gm. of the salt in 10 cc. of diluted sulphuric acid: the solution meets the requirements of the test for *arsenic*, page 1512.

One Gm. of Sodium Biphosphate shows no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid, and 0.2 Gm. shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid, page 1567.

Dry about 2 Gm. of the salt, accurately weighed, for one hour at 60° C. Raise the temperature to 100° C., and maintain that temperature until it ceases to lose weight: the loss in weight should not exceed 15 per cent (*water*).

Assay—Dry about 2 Gm. of Sodium Biphosphate to constant weight at 100° C., weigh accurately, and dissolve in 10 cc. of distilled water, add 10 cc. of a cold, saturated solution of sodium chloride, and titrate the solution with normal sodium hydroxide, using phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.1201 Gm. of NaH_2PO_4.

Dry about 0.15 Gm. of the salt to constant weight at 100° C., weigh accurately, dissolve in 10 cc. of distilled water, and neutralize the solution with normal sodium hydroxide (free from chloride), using phenolphthalein T.S. as indicator. Then add 50 cc. of tenth-normal silver nitrate, and thoroughly agitate the mixture. Gradually add reagent zinc oxide in small portions until the mixture is neutral to litmus paper, then dilute the mixture to 100 cc. with distilled water, and filter through a filter which has not been previously moistened. Reject the first 20 cc. of filtrate, collect 50 cc. of the subsequent filtrate, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate to the production of a permanent red tint. Each cc. of tenth-normal silver nitrate corresponds to 0.004002 Gm. of NaH_2PO_4.

This assay is explained on page 1463.

Preserve in tightly-closed containers.

This is used to render the urine acid in cases of cystitis with ammoniacal decomposition of the urine. Average dose, ten grains (0.6 Gm.).

SODII SALICYLAS. U. S. Sodium Salicylate

[Sod. Salicyl.]

Sodium Salicylate, when dried to constant weight at 100° C., contains not less than 99.5 per cent of $NaC_7H_5O_3$ (160.08).

Preparation—Sodium salicylate may be prepared by mixing one hundred parts of pure salicylic acid with sufficient distilled water to form a paste, and then with one hundred and four parts of pure crystallized sodium carbonate (uneffloresced) in a glass or porcelain vessel; carbon dioxide will be evolved, and sodium salicylate will remain in solution.

$$\underset{\text{salicylic acid}}{2HC_7H_5O_3} + \underset{\text{sodium carbonate}}{Na_2CO_3} = \underset{\text{sodium salicylate}}{2NaC_7H_5O_3} + \underset{\text{water}}{H_2O} + \underset{\text{carbon dioxide}}{CO_2}$$

The liquid may be strained through thoroughly washed muslin if necessary, and heated in a porcelain dish until the carbon dioxide is expelled.

It should not be filtered through ordinary paper, on account of the impurities generally present in paper; the slightest contact with iron will discolor the product, and for this reason the commercial sodium carbonate is unfitted for use in making this salt by the method just described.

If alkaline to litmus paper, enough salicylic acid must be added to be slightly in excess, and the solution should be evaporated to dryness at a low heat. If the acid is not in excess, the salt will not be white, but gray or lead colored; and if heated too much, the odor of phenol will be noticed.

Sodium salicylate is now commercially prepared from phenol by first converting the phenol into sodium phenolate, with caustic soda, according to the equation.

$$\underset{\text{phenol}}{C_6H_5OH} + \underset{\substack{\text{sodium}\\\text{hydroxide}}}{NaOH} = \underset{\substack{\text{sodium}\\\text{phenolate}}}{C_6H_5ONa} + \underset{\text{water}}{H_2O}$$

The sodium phenolate is then heated with carbon dioxide in an autoclave, the reaction that takes place being expressed as follows:

$$\underset{\substack{\text{sodium}\\\text{phenolate}}}{C_6H_5ONa} + \underset{\substack{\text{carbon}\\\text{dioxide}}}{CO_2} = \underset{\text{sodium salicylate}}{C_6H_4OHCOONa}$$

The salt is dissolved and crystallized, and then purified by recrystallization.

Description and Physical Properties—White, microcrystalline powder, or scales, or an amorphous powder. It is colorless or has not more than a faint pink tinge. It is odorless, or has a faint characteristic odor, and possesses a sweet, saline taste.

One Gm. of Sodium Salicylate is soluble in 0.9 cc. of water and in 9.2 cc. of alcohol, at 25° C. It is very soluble in boiling water and in boiling alcohol, and is soluble in 4 parts of glycerin.

Tests for Identity—When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaving a residue of sodium carbonate and carbon.

An aqueous solution of Sodium Salicylate (1 in 4) responds to the reactions for sodium, page 617, and for salicylates, page 826.

Tests for Purity—An aqueous solution of Sodium Salicylate (1 in 10) when freshly made is colorless or nearly colorless, and is neutral or slightly acid to litmus paper.

Add 1 cc. of hydrochloric acid to a solution of 1 Gm. of Sodium Salicylate in 20 cc. of distilled water, and filter the liquid: the filtrate does not decolorize 2 drops of tenth-normal iodine (*sulphite or thiosulphate*).

Add a slight excess of hydrochloric acid to an aqueous solution of the salt (1 in 50), and filter: the filtrate meets the requirements of the test for *heavy metals*, page 1519.

Assay—Proceed as directed under the assay for alkali benzoates and salicylates, page 1514, using about 2 Gm. of Sodium Salicylate, previously dried to constant weight at 100° C. and accurately weighed. Each cc. of half-normal sulphuric acid corresponds to 0.08004 Gm. of $NaC_7H_5O_3$.

This assay is explained on page 1457.

Preserve in well-closed containers, protected from heat and light.

N. F. Preparations—Caffeinæ Sodio-salicylas; Elixir Manacæ Compositus; Elixir Sodii Salicylatis; Elixir Sodii Salicylatis Compositus; Elixir Tongæ et Salicylatum; Liquor Ferri Salicylatis.

Uses—This salt is administered in rheumatic and neuralgic affections, in doses of fifteen to thirty grains (1 to 2 Gm.). Its solutions as dispensed upon prescriptions usually darken, especially in the presence of sodium bicarbonate, when the liquid becomes almost black. This is said to be due to a colored compound formed in the presence of traces of ammonia which may be present in the water or may be absorbed from the air.

SODII SULPHAS. U. S. Sodium Sulphate

[**Sod. Sulph.**—GLAUBER'S SALT]

Sodium Sulphate contains not less than 43.64 per cent and not more than 48 per cent of Na_2SO_4 (142.06), corresponding to not less than 99 per cent of the crystallized salt [$Na_2SO_4.10H_2O = 322.22$].

Preparation—This salt is largely obtained as a by-product in the manufacture of soda-ash, hydrochloric and nitric acids, ammonium chloride, etc. A typical reaction showing its production is expressed by the equation:

$$\underset{\text{sodium chloride}}{2NaCl} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{sodium sulphate}}{Na_2SO_4} + \underset{\text{hydrochloric acid}}{2HCl}$$

Description and Physical Properties—Large, colorless, odorless, transparent, monoclinic prisms, or granular crystals. The salt effloresces rapidly in the air.

One Gm. of Sodium Sulphate is soluble in about 1 cc. of water, at 25° C. It is insoluble in alcohol but soluble in glycerin.

When heated to about 33° C., Sodium Sulphate melts in its water of crystallization and on continuing the heat, maintaining it at 100° C., it loses all of its water of crystallization (about 56 per cent). At a red heat, the anhydrous salt fuses without decomposition.

Tests for Identity—An aqueous solution of Sodium Sulphate (1 in 20) responds to the reactions for sodium, page 617, and for sulphates, page 581.

Tests for Purity—An aqueous solution of the salt (1 in 10) is neutral to litmus paper.

An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page 1519.

An aqueous solution of the salt meets the requirements of the test for *arsenic*, page 1512.

Assay—Dissolve about 1 Gm. of Sodium Sulphate, accurately weighed, in 250 cc. of distilled water, acidulate the solution with 1 cc. of hydrochloric acid, and heat it to boiling. Gradually add an excess of hot barium chloride T.S., heat for thirty minutes on a water bath, collect the precipitate of barium sulphate on a filter, wash it until it is free from chlorides, then dry, ignite, and weigh. The weight of the barium sulphate thus obtained, multiplied by 0.6086, indicates its equivalent in Na_2SO_4. Each Gm. of Sodium Sulphate corresponds to not less than 0.717 Gm. and not more than 0.789 Gm. of $BaSO_4$.

This assay is explained on page 1479.

Preserve in well-closed containers, in a cool place.

N. F. Preparation—Sal Carolinum Factitium.

In using this salt in formulas, care must be employed to see that it is not effloresced, as such a salt will have lost some of its water of crystallization and therefore be correspondingly stronger than the crystalline salt.

History—This compound was first described by Johann Rudolph Glauber in 1651, who had such a high opinion of its virtues that he called it *sal mirabile*, (the wonderful salt).

Uses—It is largely used in veterinary practice as a purgative but it is not so well suited for administration to human beings, the magnesium sulphate being preferred. It may be given to adults in doses of half an ounce to one ounce (16 to 31 Gm.).

SODII THIOSULPHAS. U. S. Sodium Thiosulphate

[Sod. Thiosulph.—"SODIUM HYPOSULPHITE"]

Sodium Thiosulphate contains not less than 63.07 per cent and not more than 67.48 per cent of $Na_2S_2O_3$ (158.12), corresponding to not less than 99 per cent of the crystallized salt [$Na_2S_2O_3.5H_2O = 248.20$].

Preparation—Sodium thiosulphate, official in the U. S. P. 1890 as *sodium hyposulphite*, is made by decomposing soluble calcium thiosulphate, obtained by the oxidation of alkali waste, with either sodium sulphate or sodium carbonate:

$$\underset{\text{calcium thiosulphate}}{CaS_2O_3} + \underset{\text{sodium sulphate}}{Na_2SO_4} = \underset{\text{sodium thiosulphate}}{Na_2S_2O_3} + \underset{\text{calcium sulphate}}{CaSO_4}$$

Other methods of making "hyposulphite of soda" have been used, but the above process has superseded them because of its economy. It is now made on a very large scale.

Description and Physical Properties—Colorless, odorless, transparent, monoclinic prisms. It is stable in the air below 33° C. but efflorescent in dry air above that temperature. It is slightly deliquescent in moist air.

One Gm. of Sodium Thiosulphate is soluble in 0.5 cc. of water at 25° C. It is insoluble in alcohol.

When rapidly heated, the salt liquefies. When heated slowly until it is effloresced, and afterwards at 100° C., it undergoes partial decomposition, loses all of its water of crystallization, and at about 220° C. is decomposed, sulphur being liberated, while a residue of sodium sulphide and sodium sulphate remains.

Tests for Identity—An aqueous solution of Sodium Thiosulphate responds to the reactions for sodium, page 617, and for thiosulphates, see below.

An aqueous solution of Sodium Thiosulphate readily dissolves many compounds of silver (chloride, bromide, iodide, oxide, etc.) and discharges the color of solutions of iodine or of starch iodide.

The addition of hydrochloric acid to an aqueous solution of Sodium Thiosulphate produces a white precipitate of sulphur (distinction from *sulphite or bisulphite*).

Tests for Purity—An aqueous solution of the salt (1 in 10) is neutral or faintly alkaline to litmus paper.

An aqueous solution of Sodium Thiosulphate (1 in 20) is not rendered turbid by the addition of ammonium oxalate T.S. (*calcium*).

Add 10 cc. of diluted hydrochloric acid to 1 Gm. of the salt, evaporate to dryness on a water bath, heat the residue with 50 cc. of distilled water, and filter: a 10 cc. portion of this filtrate meets the requirements of the test for *heavy metals*, page 1519.

Add 3 cc. of nitric acid to 5 cc. of an aqueous solution of the salt (1 in 25), evaporate the solution cautiously to dryness on a water bath, treat the residue with a few cc. of distilled water, filter the liquid, and evaporate the filtrate and washings to dryness: the residue meets the requirements of the test for *arsenic*, page 1512.

Assay—Dissolve about 1 Gm. of Sodium Thiosulphate, accurately weighed in 20 cc. of distilled water, and titrate with tenth-normal iodine, starch T.S. being used as indicator. Each cc. of tenth-normal iodine corresponds to 0.01581 Gm. of $Na_2S_2O_3$.

This assay is explained on page 1470.

Preserve in well-closed containers.

N. F. Preparations—Liquor Potassii Iodidi; Unguentum Potassii Iodidi.

Uses—This compound is used in the official volumetric test solution of sodium thiosulphate, and occasionally in medicine, as an alterative and resolvent, in doses of ten to thirty grains (0.65 to 2 Gm.). Externally, it is used in baths and also as an ointment, and its saturated, aqueous solution is used in the treatment of ivy posioning. Its principal use is in the arts, as an *antichlor* in paper manufacture; while in photography, under the abbreviated name of *"hypo"*, it is invaluable as a solvent for the unaltered silver chloride or bromide in the film after development.

Tests for Thiosulphates

Thiosulphates—Solutions of thiosulphates yield with hydrochloric acid a white precipitate of sulphur which soon turns yellow, sulphur dioxide being liberated, recognizable by its odor. The addition of ferric chloride T.S. to solutions of thiosulphates, produces a dark violet color which quickly disappears.

SODII ARSENAS. N. F. Sodium Arsenate

(U. S. P. IX)

[**Sod. Arsen.**—Natrii Arsenas, P. I.]

Sodium Arsenate contains not less than 58.98 per cent nor more than 61.92 per cent of anhydrous sodium arsenate (disodium ortho-arsenate), corresponding to not less than 99 per cent of the crystallized salt ($Na_2HAsO_4.7H_2O$ = 312.08).

Preparation—A process for this salt was formerly official; it is as follows:

Take of arsenic trioxide, in fine powder, 960 *grains;* sodium nitrate, in fine powder, 816 *grains;* dried sodium carbonate, in fine powder, 528 *grains;* distilled water, boiling hot, *half a pint.* Having mixed the powders thoroughly, put the mixture into a large clay crucible, and cover it with the lid. Expose it to a full red heat until effervescence has ceased and complete fusion has taken place. Pour the fused salt on a porcelain slab, and as soon as it has solidified, and while it is still warm, put it into the hot water, and stir until it is dissolved. Filter the solution, and set it aside to crystallize. Drain the crystals, and, having dried them rapidly on filter paper, keep them in a well-stoppered bottle.

The rationale of this process is that when arsenic trioxide, sodium nitrate, and sodium carbonate are fused together, sodium pyro-arsenate is formed, while nitrous anhydride and carbon dioxide escape as gases.

$$\underset{\text{arsenic trioxide}}{As_2O_3} + \underset{\text{sodium nitrate}}{2NaNO_3} + \underset{\text{sodium carbonate}}{Na_2CO_3} = \underset{\text{sodium pyro-arsenate}}{Na_4As_2O_7} + \underset{\text{nitrous anhydride}}{N_2O_3} + \underset{\text{carbon dioxide}}{CO_2}$$

Sodium pyro-arsenate is converted into the ortho-arsenate (the official salt) by dissolving the former in water, filtering the solution, and crystallizing.

$$\underset{\text{sodium pyro-arsenate}}{Na_4As_2O_7} + \underset{\text{water}}{15H_2O} = 2(\underset{\text{sodium ortho-arsenate}}{Na_2HAsO_4,7H_2O})$$

Description and Physical Properties—Sodium Arsenate occurs as colorless, transparent, monoclinic prisms; odorless. Efflorescent in dry air, and somewhat deliquescent in moist air. *Great caution must be used in tasting it and then only in very dilute solutions.*

One Gm. of Sodium Arsenate dissolves in 1.5 cc. of water at 25° C.; also in about 1 cc. of boiling water; slightly soluble in alcohol at 25° C.; nearly insoluble in boiling alcohol.

Tests for Identity—When gently heated, the salt loses five molecules of water, and is converted into a white powder. At a higher temperature it loses all of its water of crystallization; when strongly heated, the salt fuses, and at a red heat it is converted into pyro-arsenate.

Tests for Purity—Sodium Arsenate responds to the tests for identity and purity prescribed under Sodii Arsenas Exsiccatus, when taken in proportionate amount.

Assay—Dissolve about 0.5 Gm. of Sodium Arsenate, accurately weighed, in 25 cc. of distilled water, heat the solution to 80° C. and add 10 cc. of hydrochloric acid and 3 Gm. of potassium iodide. Allow the mixture to stand for fifteen minutes at 80° C., then cool and titrate it with tenth-normal sodium thiosulphate, starch T.S. being used as indicator.

Each cc. of tenth-normal sodium thiosulphate corresponds to 0.0092985 Gm. of Na_2HAsO_4. Each Gm. of Sodium Arsenate corresponds to not less than 63.44 cc. nor more than 66.59 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1469.

Preserve it in well-closed containers.

N. F. Preparation—Sodii Arsenas Exsiccatus.

Uses—This salt exerts the valuable tonic and alterative powers of arsenous acid, although somewhat less certain in its effects than the arsenites. The dose is from one-twelfth to one-third of a grain (0.005 to 0.02 Gm.).

Antidotes—(See Part XV, on Antidotes).

SODII ARSENAS EXSICCATUS. N. F. Exsiccated Sodium Arsenate

(U. S. P. IX)

[Sod. Arsen. Exsic.]

Exsiccated Sodium Arsenate contains, when dried to constant weight at 150° C., not less than 98 per cent of Na_2HAsO_4 (185.97).

Sodium Arsenate, in crystals, a sufficient quantity.

Break the crystals into small fragments, and allow them to effloresce at a temperature between 40° and 50° C., until they are completely disintegrated; then gradually increase the temperature to 150° C., and continue the drying until the product ceases to lose weight. Reduce it to a fine powder, and transfer it to dry, well-closed containers.

Description and Physical Properties—Exsiccated Sodium Arsenate occurs as an odorless, amorphous, white powder. It is slightly hygroscopic. *Great caution must be used in tasting it and then only in very dilute solutions.*

One Gm. of Exsiccated Sodium Arsenate dissolves in 3.1 cc. of water at 25° C.; also in 1.3 cc. of boiling water; slightly soluble in alcohol at 25° C.; nearly insoluble in boiling alcohol.

Tests for Identity—Its aqueous solution (1 in 20) is alkaline to litmus.

It imparts an intensely yellow color to a non-luminous flame.

An aqueous solution of the salt (1 in 20) yields a white precipitate with barium chloride T.S., and a dark red precipitate with silver nitrate T.S.; both of these precipitates are soluble in nitric acid.

Tests for Purity—Add 5 cc. of tenth-normal silver nitrate to 2 cc. of an aqueous solution of the salt (1 in 20), and redissolve the precipitate with the aid of a slight excess of ammonia water; no black precipitate of reduced silver appears on boiling for one minute (*arsenite*).

Add 1 cc. of ammonium sulphide T.S. to 5 cc. of an aqueous solution of the salt (1 in 100), no dark coloration appears (*lead, copper, or iron*).

Assay—Dissolve about 0.3 Gm. of Exsiccated Sodium Arsenate, dried to constant weight at 150° C. and accurately weighed, in 25 cc. of distilled water, in a glass-stoppered bottle, heat the solution to 80° C. and add 10 cc. of hydrochloric acid and 3 Gm. of potassium iodide. Allow the mixture to stand in the stoppered bottle for fifteen minutes at 80° C., then cool and titrate it with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. It shows, in the dried salt, not less than 98 per cent of Na_2HAsO_4.

Each cc. of tenth-normal sodium thiosulphate corresponds to 0.0092985 Gm. of Na_2HAsO_4. Each Gm. of Exsiccated Sodium Arsenate, previously dried, corresponds to not less than 105.4 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1469.

Preserve it in well-closed containers.

N. F. Preparations—Liquor Sodii Arsenatis, Liquor Sodii Arsenatis Dilutus.

Uses—Exsiccated Sodium Arsenate is used in making the official solutions (see above). The advantage in using it in preference to sodium arsenate is that greater definiteness is secured; the latter salt as found in commerce is more or less effloresced, and the solution if made from it would be variable in its arsenical strength. Sixty parts of exsiccated sodium arsenate represent about 100 parts of the official crystallized salt. The *dose* is one-twentieth grain (0.003 Gm.).

Antidotes—(See Part XV, on Antidotes).

LIQUOR SODII ARSENATIS. N. F. Solution of Sodium Arsenate
(U. S. P. IX)

[Liq. Sod. Arsenat.]

An aqueous solution containing not less than 0.975 Gm., and not more than 1.025 Gm. of Na_2HAsO_4 (185.97) in each 100 cc.

	Metric	Alternative
Exsiccated Sodium Arsenate, previously dried to constant weight at 150° C.	**10 Gm.**	146 gr.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve the exsiccated sodium arsenate in sufficient distilled water to make the product measure 1000 cc. [2 pints].

Solution of Sodium Arsenate is a clear, colorless, odorless liquid, faintly alkaline to litmus paper.

For making the following identity tests, evaporate 500 cc. of the Solution to a volume of 50 cc. and the tests applied to this concentrated solution.

A white precipitate is formed when the Solution is mixed with barium chloride T.S. A reddish brown precipitate is formed when the Solution is added to silver nitrate T.S.

A yellow precipitate is formed when hydrogen sulphide T.S. is added to Solution of Sodium Arsenate previously acidulated with hydrochloric acid.

Assay—Place 25 cc. of Solution of Sodium Arsenate, accurately measured, in a glass-stoppered flask; heat to 80° C. and add 10 cc. of hydrochloric acid and 3 Gm. of potassium iodide. Allow the mixture to stand at 80° C. for fifteen minutes, then cool and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate consumed corresponds to 0.0092985 Gm. of Na_2HAsO_4.

This assay is explained on page 1469.

Uses—A convenient form for administering sodium arsenate.

Average dose—3 minims (0.2 cc.).

LIQUOR SODII ARSENATIS DILUTUS. N. F. Diluted Solution of Sodium Arsenate

[**Liq. Sod. Arsenat. Dil.**—Liquor Sodii Arsenatis, Pearsonii. N. F. IV., Pearson's Solution of Arsenic, Liquor Arsenicalis Pearsonii]

An aqueous solution containing not less than 0.0975 Gm. and not more than 0.1025 Gm. of Na_2HAsO_4 (185.97) in each 100 cc.

	Metric	Alternative
Exsiccated Sodium Arsenate	**1 Gm.**	14½ gr.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve the exsiccated sodium arsenate in the distilled water and filter the solution.

Note—This preparation must not be confounded with Liquor Sodii Arsenatis, *which is ten times as strong as Pearson's solution.*

Pearson's solution of Sodium Arsenate is a clear, colorless solution without odor and taste. It is neutral to litmus paper.

Specific gravity: about 1.0003 at 25° C.

Evaporate 100 cc. of the Solution at a temperature not exceeding 100° C.; it leaves not less than 0.0999 Gm., nor more than 0.110 Gm. of residue.

Incinerate the residue from 100 cc. of the Solution; it leaves not more than 0.100 Gm. of ash.

Silver nitrate T.S. added to the Solution produces a reddish-brown precipitate, soluble in nitric acid (*Arsenites, Phosphates*).

Assay—Pour into a tared flask 100 cc. of Diluted Solution of Sodium Arsenate, accurately measured, heat to 80° C. and add 3.5 cc. of hydrochloric acid and 1 Gm. of potassium iodide. Allow the mixture to stand for 15 minutes at 80° C., in a glass-stoppered flask, cool and then

titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator.

Each cc. of tenth-normal sodium thiosulphate used corresponds to 0.0092985 Gm. of Na_2HAsO_4. Each Gm. of Pearson's Solution of Sodium Arsenate corresponds to not less than 0.105 nor more than 0.110 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1469.

Uses—A convenient form for administering sodium arsenate. The pharmacist should be familiar with this solution as it is still occasionally prescribed and is only one-tenth as strong as the International standard solution of sodium arsenate (see page 637).

Average dose—Metric, 2 cc.—Apothecaries, 30 minims.

One average dose contains:

0.002 Gm. or $\frac{1}{35}$ grain of Exsiccated Sodium Arsenate.

SODII GLYCEROPHOSPHAS. N. F. Sodium Glycerophosphate

(U. S. P. IX)

[Sod. Glycerophos.—Sodium Glycerinophosphate]

Hydrated Sodium Glycerophosphate containing not less than 68 per cent of the anhydrous salt ($Na_2C_3H_7PO_6$ or $C_3H_5(OH)_2PO_4Na_2 = 216.11$).

Preparation—This salt may be made by double decomposition between barium or calcium glycerophosphate and sodium carbonate or by neutralizing glycerophosphoric acid with sodium carbonate and concentrating the solution *in vacuo*. The *glycerophosphoric acid* is prepared by heating glycerin with phosphoric acid, at a temperature between 105° and 110° C. (221° to 230° F.). It is a clear, colorless, odorless liquid, of an acid taste, containing about 20 per cent of the acid, $PO_3H_9O_6(C_3H_5(OH)_2OPO(OH)_2)$. Specific gravity 1.104.

Description and Physical Properties—Sodium Glycerophosphate occurs as white monoclinic plates or scales, or as a white powder, having a saline taste; odorless.

It is very soluble in cold or hot water; nearly insoluble in alcohol.

Tests for Identity—An aqueous solution of the salt (1 in 20) is alkaline to litmus and to phenolphthalein T.S.

When strongly heated the salt is decomposed, evolving inflammable vapors, and at a red heat is converted into sodium pyrophosphate.

Tests for Purity—Dissolve 1 Gm. of Sodium Glycerophosphate in 10 cc. of distilled water and add 3 drops of phenolphthalein T.S.; the red color produced is discharged by the addition of 1.5 cc. of tenth-normal sulphuric acid (*free alkali*).

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

Add an equal volume of cold ammonium molybdate T.S. to 10 cc. of an aqueous solution of the salt (1 in 20): no precipitate is formed within one hour (*phosphates*). On heating this mixture a yellow precipitate is formed.

Triturate 1 Gm. of the salt with 20 cc. of dehydrated alcohol, filter the mixture, evaporate the filtrate on a water bath and dry the residue for one hour at a temperature not exceeding 70° C.: the weight of this residue does not exceed 0.01 Gm. (*alcohol-soluble impurities*).

Assay—Dissolve about 3 Gm. of the salt, accurately weighed, in 30 cc. of distilled water and titrate with half-normal hydrochloric acid, using methyl orange T.S. as indicator.

Each cc. of half-normal hydrochloric acid used corresponds to 0.10805 Gm. of $Na_2C_3H_7PO_6$. Each Gm. of Sodium Glycerophosphate corresponds to not less than 6.29 cc. of half-normal hydrochloric acid.

This assay is explained on page 1459.

N. F. Preparations—Elixir Calcii et Sodii Glycerophosphatum, Elixir Glycerophosphatum Compositum, Elixir Terpini Hydratis et Creosoti Compositum.

Uses—It is employed, usually in combination with other glycerophosphates, in syrups or elixirs, in wasting or nervous diseases, as a "nerve tonic". The dose is usually four grains (0.25 Gm.).

SODII HYPOPHOSPHIS. N. F. Sodium Hypophosphite

(U. S. P. IX)

[Sod. Hypophos.]

Sodium Hypophosphite contains not less than 98 per cent of $NaPH_2O_2.H_2O$ (106.07).

Caution should be observed in dispensing Sodium Hypophosphite, as an explosion is liable to occur when it is triturated or heated with nitrates, chlorates or other oxidizing agents.

Preparation—This salt is prepared by mixing a solution of six ounces of calcium hypophosphite in four pints of water with a solution of ten ounces of sodium carbonate in one and a half pints of water.

$$\underset{\text{calcium hypophosphite}}{Ca(H_2PO_2)_2} + \underset{\text{sodium carbonate}}{Na_2CO_3} = \underset{\text{sodium hypophosphite}}{2NaH_2PO_2} + \underset{\text{calcium carbonate}}{CaCO_3}$$

Double decomposition takes place, with the formation of calcium carbonate and sodium hypophosphite, of which the latter is held in solution, and the former precipitated. After filtration to separate the calcium carbonate, the solution is evaporated until a pellicle forms, and then stirred constantly until the salt granulates, the heat being continued. If required quite pure, the granulated salt is dissolved in official alcohol, and the liquid, having been evaporated to a syrupy consistence, is set aside to crystallize.

Sodium hypophosphite has been known to explode with violence during the evaporation of its solution. This has even occurred when the heat was applied by means of a water bath. Evaporation, therefore, should be performed below 100° C. (212° F.).

$$\underset{\text{sodium hypophosphite}}{5NaH_2PO_2} = \underset{\text{sodium pyrophosphate}}{Na_4P_2O_7} + \underset{\text{sodium metaphosphate}}{NaPO_3} + \underset{\text{hydrogen phosphide}}{2PH_3} + \underset{\text{hydrogen}}{2H_2}$$

The gases evolved by heat are hydrogen and hydrogen phosphide. The latter is well known to be spontaneously inflammable.

This acid is a powerful deoxidizer, and as it reduces mercury and silver from their combinations, it should not be prescribed with either.

Description and Physical Properties—Sodium Hypophosphite occurs as small, colorless, transparent, rectangular plates of a pearly luster, or as a white, granular powder; odorless, and having a saline taste. It is deliquescent on exposure to moist air.

One Gm. of Sodium Hypophosphite dissolves in 1 cc. of water at 25° C.; also in about 0.15 cc. of boiling water; soluble in alcohol, slightly soluble in dehydrated alcohol, and freely soluble in glycerin at 25° C.; freely soluble in boiling alcohol.

Tests for Identity—An aqueous solution of Sodium Hypophosphite (1 in 20) is neutral or slightly alkaline to litmus.

When heated in a test tube, the salt at first loses its water of crystallization, and upon further heating is decomposed, evolving spontaneously inflammable hydrogen phosphide, which burns with a bright yellow flame. To a non-luminous flame the salt imparts an intensely yellow color.

When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, with agitation, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. Upon the further addition of the solution of Sodium Hypophosphite, the precipitate becomes gray from reduction to metallic mercury.

Tests for Purity—A solution of 1 Gm. of the salt in about 10 cc. of distilled water requires not more than 1.5 cc. of tenth-normal hydrochloric acid for neutralization, methyl orange T.S. being used as indicator.

Heat 5 cc. of an aqueous solution of the salt (1 in 5) in a test tube with 0.5 cc. of diluted hydrochloric acid on a water bath for thirty minutes; no offensive odor is developed.

Measure 5 cc. of an aqueous solution of the salt (1 in 25) into a beaker containing 3 cc. of nitric acid, diluted with about 10 cc. of distilled water, and evaporate the mixture to dryness on a water bath; the residue meets the requirements of the test for arsenic (see page 1512).

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

Add magnesia mixture T.S. to 10 cc. of an aqueous solution of the salt (1 in 20), made alkaline with ammonia water; it is not affected within one minute (*phosphate*).

Assay—Dissolve about 1 Gm. of Sodium Hypophosphite, previously dried for twenty-four hours over sulphuric acid and accurately weighed, in 10 cc. of distilled water, add 10 cc. of nitric acid and evaporate the solution to dryness on a water bath. Dissolve the residue in 20 cc. of distilled water, add a drop of phenolphthalein T.S. and sufficient special potassium hydroxide T.S. (See Reagents U. S. P.) to produce a pink color, and then dilute to exactly 100 cc. with distilled water. Transfer 10 cc. of this solution to a 100 cc. graduated flask, add 50 cc. of tenth-normal silver nitrate and proceed from this point as directed in the assay under *Potassii Hypophosphis*.

Each cc. of tenth-normal silver nitrate used corresponds to 0.0035357 Gm. of $NaPH_2O_2.H_2O$. Each Gm. of Sodium Hypophosphite corresponds to not less than 277.2 cc. of tenth-normal silver nitrate.

This assay is explained on page 1464.

Preserve it in well-closed containers.

N. F. Preparations—Emulsum Olei Morrhuæ cum Hypophosphitibus, Liquor Hypophosphitum Compositus, Syrupus Calcii et Sodii Hypophosphitum, Syrupus Hypophosphitum, Syrupus Hypophosphitum Compositus.

Uses—Sodium hypophosphite is used in phthisis and other wasting diseases, and in cases of defective nerve nutrition; pharmaceutically it is an ingredient in the various official and unofficial preparations of the hypophosphites; the dose is 15 grains (1 Gm.).

SODII PERBORAS. N. F. Sodium Perborate

(U. S. P. IX)

[Sod. Perbor.]

Sodium Perborate contains not less than 9 per cent of available oxygen, corresponding to about 86.5 per cent of $NaBO_3.4H_2O$ (154.06).

Preparation—It is made by mixing 248 parts of boric acid with 78 parts of sodium peroxide, pouring the mixture slowly into 2000 parts of cold water, acidified with sulphuric acid, and separating and drying the crystals at 50° C. (122° F.).

Description and Physical Properties—Sodium Perborate occurs as white, crystalline granules or as a powder; odorless, and having a saline taste. It is stable in cool and dry air, but is decomposed with the evolution of oxygen in warm or moist air.

Sodium Perborate is soluble in water.

Tests for Identity—A saturated aqueous solution of the salt is alkaline to litmus or phenolphthalein T.S. In aqueous solution the salt is decomposed into sodium metaborate and hydrogen dioxide, the solution gradually evolving oxygen. Oxygen is evolved more rapidly if the solution is warmed.

The salt imparts an intensely yellow color to a non-luminous flame. Turmeric paper, if moistened with an aqueous solution of the salt which has been acidulated with hydrochloric acid, becomes brown in color, particularly on drying; on moistening the dried test paper with ammonia water, the color is changed to greenish black.

Agitate a mixture of 1 cc. of an aqueous solution of the salt (1 in 50), 1 cc. of diluted sulphuric acid, a few drops of potassium dichromate T.S., and 2 cc. of ether; the ether acquires a blue color.

Tests for Purity—Strongly heat 0.5 Gm. of the salt in a platinum crucible, and dissolve the residue in 25 cc. of distilled water with the aid of a few drops of hydrochloric acid; 10 cc. of the resulting solution does not respond to the test for heavy metals (see page 1519).

Assay—Dissolve about 0.25 Gm. of the salt, accurately weighed, in a mixture of 50 cc. of distilled water and 10 cc. of diluted sulphuric acid and titrate the solution with tenth-normal potassium permanganate.

Each cc. of tenth-normal potassium permanganate corresponds to 0.0008 Gm. of available oxygen. Each Gm. of Sodium Perborate corresponds to not less than 112.5 cc. of tenth-normal potassium permanganate.

This assay is explained on page 1474.

Preserve it in well-closed containers, in a cool place.

N. F. Preparation—Dentifricium.

Uses—It is used as an antiseptic dusting powder or as a wash in aqueous solution for wounds and ulcers, also used in toilet preparations as an antiseptic and bleaching agent. Its activity depends upon the liberation of nascent oxygen when in contact with animal matter or animal ferments. The dose is 1 grain (0.065 Gm.).

LIQUOR SODÆ ET MENTHÆ. N. F. Solution of Soda and Mint

[Liq. Sod. et Menth.—Mistura Sodæ et Menthæ, Soda Mint]

	Metric	Alternative
Sodium Bicarbonate	**50 Gm.**	1 oz. av. 293 gr.
Aromatic Spirit of Ammonia	**20 cc.**	307 min.
Spearmint Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve the sodium bicarbonate in 750 cc. [24 fl. oz.] of spearmint water, add the aromatic spirit of ammonia, and then sufficient spearmint water to make the product measure 1000 cc. [2 pints].

Solution of Soda and Mint is a colorless, transparent solution, with an aromatic, mint-like odor and a mint-like, alkaline taste.

Add to 3 cc. of the Solution a few drops of hydrochloric acid: an immediate effervescence ensues.

Heat 5 cc. of the Solution in a test tube with 3 cc. of potassium hydroxide T.S.: a piece of moistened red litmus paper placed inside the mouth of the tube, but not in contact with the side, will turn blue. A pink color is produced if 1 drop of phenolphthalein T.S. is added to 3 cc. of the Solution.

A non-luminous flame is colored intensely yellow when a clean platinum wire is dipped into the Solution and held in the flame.

Approximate alcohol content, by volume, 1 per cent.

Uses—It is used as an antacid in doses of two fluidrachms (8 cc.), and for those who prefer the flavor, the N. F. directs that Peppermint Water may be used in place of the Spearmint Water.

LIQUOR SODII BORATIS COMPOSITUS. N. F. Compound Solution of Sodium Borate

[Liq. Sod. Bor. Co.—Dobell's Solution]

	Metric	Alternative
Sodium Borate	15 Gm.	219 gr.
Sodium Bicarbonate	15 Gm.	219 gr.
Liquefied Phenol	3 cc.	46 min.
Glycerin	35 cc.	1 fl. oz. 58 min.
Water, a sufficient quantity,		
To make	1000 cc.	2 pints

Dissolve the sodium borate and sodium bicarbonate in about 500 cc. [1 pint] of water, add the glycerin and liquefied phenol, and allow the mixture to stand half an hour or until the effervescence has ceased; then add sufficient water to make the product measure 1000 cc. [2 pints], and filter.

Compound Solution of Sodium Borate is a clear, yellowish liquid, with a phenol-like odor. It is strongly alkaline to litmus paper and phenolphthalein T.S.

Add a few drops of hydrochloric acid to 3 cc. of the Solution: an immediate effervescence results.

The Solution turns turmeric paper red-brown; if this paper is then moistened with ammonia T.S. it is changed to a dark green color.

When prepared as directed in the N. F. an effervescence always occurs, due to the decomposition of the sodium borate by the glycerin and the freed boric acid liberating CO_2 from the bicarbonate. The sodium borate reacts with the glycerin to form glyceryl borate and sodium metaborate, as follows:

$$\underset{\text{sodium tetraborate}}{Na_2B_4O_7} + 2\underset{\text{glycerin}}{C_3H_5OH} = \underset{\text{sodium metaborate}}{2NaBO_2} + \underset{\text{glyceryl orthoborate}}{2C_3H_5BO_3} + \underset{\text{water}}{3H_2O}$$

The glyceryl borate promptly undergoes hydrolysis with the liberation of free boric acid, according to the equation:

$$\underset{\text{glyceryl orthoborate}}{C_3H_5BO_3} + \underset{\text{water}}{H_2O} = \underset{\text{glycerin}}{C_3H_5(OH)_3} + \underset{\text{boric acid}}{H_3BO_3}$$

The boric acid attacks the bicarbonate of soda in the usual manner, liberating carbon dioxide, which causes the effervescence:

$$\underset{\text{boric acid}}{4H_3BO_3} + \underset{\text{sodium bicarbonate}}{2NaHCO_3} = \underset{\text{sodium tetraborate}}{Na_2B_4O_7} + \underset{\text{carbon dioxide}}{2CO_2} + \underset{\text{water}}{7H_2O}$$

Uses—This solution is used as an alkaline, mildly antiseptic nasal wash or spray.

LIQUOR SODII CITRATIS. N. F. Solution of Sodium Citrate

[Liq. Sod. Cit.—Mistura Sodii Citratis, Potio Riverii]

An aqueous solution containing not less than 2.5 Gm. and not more than 3 Gm. of $Na_3C_6H_5O_7.2H_2O$ (94.10) in each 100 cc.

	Metric	Alternative
Citric Acid	2.0 Gm.	73 gr.
Sodium Bicarbonate	2.5 Gm.	91 gr.
Distilled Water	100.0 cc.	8 fl. oz.

Dissolve the citric acid in the distilled water contained in a strong bottle of about 125 cc. [10 fl. oz.] capacity, add the sodium bicarbonate, dissolve it by gentle agitation and immediately stopper the bottle securely.

This preparation should not be dispensed unless it has been recently prepared.

Solution of Sodium Citrate is a slightly effervescent, clear, colorless, and odorless, aqueous liquid, with a pleasantly acidulous and saline taste and a slightly acid reaction.

When a clean platinum wire is moistened with the Solution and held in a non-luminous flame, it imparts an intensely yellow color.

When 10 cc. of the Solution is carefully neutralized with ammonia T.S., and an equal volume of calcium chloride T.S. added, and the mixture boiled, a white precipitate is produced.

Assay—Evaporate 80 cc. of Solution of Sodium Citrate to dryness in a platinum dish, carefully carbonize and proceed as directed for the assay for alkali salts of organic acids.

This assay is explained on page 1456.

Uses—This solution is used as a diuretic and diaphoretic in doses of two to four fluidrachms (8 to 15 cc.). Its uses are similar to those of solution of potassium citrate, although only about one-third the strength.

LIQUOR SODII PHOSPHATIS COMPOSITUS. N. F. Compound Solution of Sodium Phosphate

[Liq. Sod. Phos. Co.]

	Metric	Alternative
Sodium Phosphate, in uneffloresced crystals	**1000 Gm.**	33 oz. av. 167 gr.
Citric Acid	**130 Gm.**	4 oz. av. 149 gr.
Glycerin	**150 cc.**	4 fl. oz. 384 min.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Heat the mixture of sodium phosphate and citric acid in a glass or porcelain vessel on a water bath until liquefied. Filter the solution while hot into a vessel which has just previously been rinsed with boiling water. Add the glycerin and sufficient distilled water, just previously boiled, to make the product measure 1000 cc. [2 pints].

It is important that *uneffloresced* crystals of sodium phosphate be used in making this solution, as it is nearly saturated. Should an effloresced salt be employed with its greater percentage of anhydrous sodium phosphate, the solution is likely to crystallize.

Should sodium phosphate in partly effloresced form be used, the salt should be first covered or thoroughly washed with distilled water, and, when the efflorescence has disappeared, the clear crystals should be removed from the water and air-dried; or a small quantity of the sample may be dried with heat, as directed under *Sodii Phosphas Exsiccatus* (U. S. P.), and the percentage of moisture determined. When the amount of water present is known, a proportionately smaller quantity of the effloresced salt may be taken.

Compound Solution of Sodium Phosphate is a clear, colorless liquid, of a thick, syrupy consistence, practically odorless and having a cooling, saline taste.

It is acid to litmus paper.

Specific gravity: about 1.385 at 25° C.

Not more than 2.218 Gm. of ash remains on evaporating 10 cc. of the solution and igniting the residue.

Dilute 5 cc. of the solution with 5 cc. of distilled water and add 5 cc. of magnesia mixture T.S.: a white crystalline precipitate is formed.

Preserve the Solution in well-stoppered bottles, in a moderately warm place.

Uses—This solution, which represents the salt in the proportion of 1 Gm. in each cc. furnishes a convenient form for the administration of sodium phosphate, the citric acid is added to prevent the salt from crystallizing and the glycerin assists in its preparation, and especially in preventing the development of micro-organisms. The dose is two fluidrachms (8 cc.).

Unofficial Salts of Sodium

Sodii Ammonii et Hydrogenii Phosphas
$NH_4NaHPO_4+4H_2O$
Sodium, Ammonium, Hydrogen Phosphate

Known as microcosmic salt. It is soluble in water to which it imparts an alkaline reaction. When strongly heated it fuses, evolving water and ammonia, and leaves a transparent glass of sodium metaphosphate

Sodii et Argenti Thiosulphas
$2Na_2S_2O_3+Ag_2S_2O_3$
Sodium and Silver Thiosulphate

A water-soluble crystalline double-salt having a sweet taste. Its solution is decomposed by mineral acids, yielding sulphur, sulphur dioxide, water, and sodium and silver salt of the acid. It forms when sodium thiosulphate dissolves the silver halides

Sodii Bisulphis, $NaHSO_3$
Sodium Bisulphite (U. S. P. VIII)

A white crystalline powder having a disagreeable taste and a slight sulphurous odor. It is soluble in water and insoluble in alcohol. Sodium bisulphite is largely used in paper manufacture, as a disinfectant and antiseptic, and in calico-bleaching

Sodii Chloras, $NaClO_3$
Sodium Chlorate (U. S. P. VIII)

Colorless and odorless crystals with a cooling saline taste; soluble in water and in alcohol. It is a powerful oxidizing agent and should not be triturated with any combustible substance. Sodium chlorate is more soluble and richer in oxygen than potassium chlorate but is less desirable in dry explosives because of its tendency to be hygroscopic in mixtures

Unofficial Salts of Sodium—*Continued*

Sodii Cyanidum, NaCN Sodium Cyanide (U. S. P. IX)	White, amorphous pieces, or a white granular powder, deliquescent in the air and exhaling the odor of hydrocyanic acid. It is very poisonous and should be handled with great caution. It is used in medicine, in electroplating, as an insecticide, in the extraction of gold and silver and in the heat treatment of metals
Sodii Ethylas, C_2H_5NaO Sodium Ethylate	A derivative of ethyl alcohol in which the hydrogen of the hydroxyl is replaced by an atom of sodium. It is used in surgery as a caustic. This compound is decomposed by water with the formation of ethyl alcohol and sodium hydroxide
Sodii Ethylsulphas, $C_2H_5NaSO_4+H_2O$ Sodium Ethylsulphate, Sodium Sulphovinate	A white granular powder having a cooling, rather aromatic taste. It is deliquescent and very soluble in water. This compound makes a very pleasant purgative but is expensive and unstable
Sodii Nitras, $NaNO_3$ Sodium Nitrate (U. S. P. VIII)	Commonly called *chili saltpetre* and *cubic nitre*. Colorless crystals, without odor, and with a saline, slightly bitter taste. It is readily soluble in water, slightly soluble in alcohol. It is largely used in the manufacture of nitric acid and of potassium nitrate and in fertilizers
Sodii Nitro-Prussidum $Na_2Fe(CN)_5NO+2H_2O$ Sodium Nitro-Prusside	Ruby-red transparent crystals, soluble in water. It is used as a reagent for sulphides in analytical chemistry. It is also used in testing silk for the presence of animal hair
Sodii Phenolas, NaC_6H_5O Sodium Phenolate	White deliquescent crystals, soluble in water and alcohol. Sodium phenolate is used as an antiseptic, in a mixture for military gas masks that absorbs phosgene, and in the manufacture of salicylic acid. When acidified with a mineral acid it yields phenol and a sodium salt of the acid used
Sodii Phenolsulphonas, $NaC_6H_5O.SO_3.2H_2O$, Sodium Phenolsulphonate Sodium Sulphocarbolate (U. S. P. IX)	Colorless, transparent crystalline granules; somewhat efflorescent in dry air. It is soluble in water and is used as an antifermentative, or intestinal antiseptic. The dose is from 4 to 20 grains (0.26 to 1.3 Gm.)
Sodium Phosphate, Tribasic, Na_3PO_4	*Trisodium phosphate, sodium orthophosphate* sometimes erroneously called *sodium triphosphate* or simply *triphosphate*, is a cheap compound made and sold upon an enormous scale and used for all purposes where a mild alkali is needed, as in bottle washing, laundrying, scrubbing, etc. It has appeared upon the market in numerous package forms under coined trade names and sold usually at fancy prices, for *cleaning paint brushes, removing old paint and varnish*, and for general washing and cleaning purposes Some of these commercial forms are intensified in power by the addition of caustic soda, others are rendered milder by the addition of sodium bicarbonate. Some of the trisodium phosphate on the market consists simply of a mixture of soda ash and *disodic hydrogen phosphate* in molecular proportions
Sodii et Platini Chloridum $2NaCl.PtCl_4+6H_2O$ Sodium and Platinum Chloride	A yellow to red crystalline substance; very soluble in water and alcohol—differing in this respect from the corresponding salt of potassium
Sodii Pyrophosphas, $Na_4P_2O_7+10H_2O$ Sodium Pyrophosphate (U. S. P. VIII)	Colorless, transparent crystals without odor and with a cooling saline taste. It is soluble in water and insoluble in alcohol. It is used in the manufacture of pyrophosphate of iron
Sodium Sesquicarbonate, $Na_4H_2(CO_3)_3.3H_2O$	Under this name there has appeared upon the market a crystalline salt used for cleaning paint brushes, removing old paint and varnish and for general cleaning purposes, as a substitute for and milder than soda ash. It is made by boiling a solution of sodium bicarbonate to remove a portion of the CO_2 and then crystallizing
Sodii Silicas, Na_2SiO_3 Sodium Silicate, Water Glass, Soluble Glass	White to grayish-white lumps or powder, soluble in water, insoluble in alcohol. It is used as an egg preservative, for fire proofing fabrics, stiffening bandages, filling for soaps, and for a variety of other purposes
Sodii Silicofluoridum, Na_2SiF_6 Sodium Silico-Fluoride	A white, odorless and tasteless granular powder; very slightly soluble in cold water, insoluble in alcohol. It is used in ceramics and has been used in medicine
Sodii Stannas, Na_2SnO_3 Sodium Stannate	Commonly called *preparing salt*. White powder or lumps soluble in water, insoluble in alcohol. It is used as a mordant in dyeing
Sodii Sulphis Exsiccatus, Na_2SO_3 Exsiccated Sodium Sulphite (U. S. P. IX)	A white powder, tending to oxidize to sodium sulphate when exposed to the air. It is soluble in water. Exsiccated sodium sulphite is an antifermentative. The dose is from 10 to 30 grains (0.65 to 1.9 Gm.). It is sometimes used as a bleaching agent in confectionery, or as a food preservative, although such use is illegal
Sodii Tartras, $Na_2C_4H_4O_6+2H_2O$ Sodium Tartrate	A white crystalline substance; soluble in water and insoluble in alcohol. It has been used in medicine but is of very little importance
Sodii Valeras, $NaC_5H_9O_2$ Sodium Valerate	A white, deliquescent, very soluble salt having a disagreeable odor and sweetish taste. It has been used in medicine but more largely in the preparation of other valerates by double decomposition

CHAPTER XLVIII

THE LITHIUM SALTS

Li; 6.94

Lithium is from a Greek word meaning "stone", indicating its discovery in a mineral.

The lithium salts resemble those of potassium and sodium. The metal lithium is comparatively rare, for although the element is widely distributed in nature, it occurs in such small quantities that the necessary labor to extract it makes it comparatively expensive; it is found as a silicate in combination with other metals in certain minerals as *lithium mica, lepidolite, petalite,* and *spodumene,* and in a few mineral waters.

Lithium is a metal resembling potassium and sodium, although much less prone to oxidation; it is soft, *and is the lightest of all known metals,* having a specific gravity of about 0.5891. Heated in the air, lithium ignites at a temperature above its fusing point, burning with a bright white light, but its salts burn with an intense red flame; when thrown on water, it oxidizes, but does not fuse like sodium. Chemically, lithium is a monad, like sodium and potassium.

Tests for Lithium

Lithium salts moistened with hydrochloric acid impart an intense, crimson color to a non-luminous flame. Solutions of lithium salts are not precipitated by diluted sulphuric acid or soluble sulphates (*difference from strontium*).

LITHII BENZOAS. N. F. Lithium Benzoate
[Lith. Benz.]

Lithium Benzoate contains, when dried for 24 hours over sulphuric acid, not less than 98.5 per cent of $LiC_7H_5O_2$ (128.01).

It is prepared by decomposing lithium hydroxide with benzoic acid according to the following equation:

$$\underset{\text{lithium hydroxide}}{Li(OH)} + \underset{\text{benzoic acid}}{HC_7H_5O_2} = \underset{\text{lithium benzoate}}{LiC_7H_5O_2} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—A white powder or small crystalline scales. It is odorless, and is stable in the air.

One Gm. of Lithium Benzoate dissolves in about 3 cc. of water and in about 16 cc. of alcohol at 25° C. It is slightly more soluble in these solvents when hot.

Tests for Identity—When heated the salt at first fuses, then at higher temperatures it chars, emitting inflammable vapors having a benzoin-like odor and finally leaves a residue of lithium carbonate and carbon. This residue is alkaline to litmus paper, effervesces with acids and colors a non-luminous flame crimson.

The addition of mineral acids to an aqueous solution of Lithium Benzoate (1 in 20) produces a voluminous white precipitate of benzoic acid. Ferric chloride added to the aqueous solution produces a flesh colored precipitate of ferric benzoate.

Tests for Purity—Dissolve 0.6 Gm. of Lithium Benzoate in 25 cc. of water, add 5 cc. of diluted hydrochloric acid, filter and wash the precipitate with about 25 cc. of distilled water. Evaporate the combined filtrate and washings on a water bath to a small volume in a beaker or dish, then transfer completely with the aid of a little water into a flat-bottomed flask of about 50 cc. capacity and evaporate almost to dryness on a water bath. Add 10 cc. of amyl alcohol and cautiously heat the mixture until all the water has evaporated. The removal of the water from the amyl alcohol mixture may be facilitated by passing a current of air through the hot solution. Then add three drops of hydrochloric acid and boil the solution for three minutes. If any insoluble residue remains, collect it on a filter, wash it with amyl alcohol and dry at 110° C. to constant weight. The weight of the residue should not exceed 0.004 Gm. (*other alkalies*).

Dissolve about 1 Gm. of Lithium Benzoate in 20 cc. of water in a separatory funnel, add 10 cc. of diluted sulphuric acid, extract the precipitate of benzoic acid by shaking with two portions of

20 cc. each of ether, and evaporate the ether solution to dryness at a low temperature. One half Gm. of the residue of benzoic acid thus obtained complies with the test for *chlorine* described in the U. S. P. under *Acidum Benzoicum*.

The aqueous layer from the above test, warmed to expel ether and diluted to 50 cc. does not respond to the test for *heavy metals*.

Assay—Weigh accurately about 0.5 Gm. of Lithium Benzoate, which has previously been dried for 24 hours over sulphuric acid, mix it with 1 Gm. of dried and powdered ammonium sulphate and cautiously ignite in a porcelain crucible to constant weight. The weight of the residue of lithium sulphate thus obtained, multiplied by 2.328, represents its equivalent of Lithium Benzoate.

This assay is explained on page 1480.

N. F. Preparation—Elixir Hydrangeæ et Lithii.

Uses—A diuretic and antirheumatic. It is given in fifteen grain (1 Gm.) doses.

LITHII BROMIDUM. N. F. Lithium Bromide

(U. S. P. IX)

[Lith. Brom.]

Lithium Bromide contains, when dried for twenty-four hours over sulphuric acid, not less than 85 per cent of LiBr (86.86).

Preparation—Lithium bromide is best prepared by carefully neutralizing lithium carbonate, or lithium hydroxide, with hydrobromic acid, and by subsequent crystallization of the salt from solution.

$$\underset{\text{lithium carbonate}}{Li_2CO_3} + \underset{\text{hydrobromic acid}}{2HBr} = \underset{\text{lithium bromide}}{2LiBr} + \underset{\text{water}}{H_2O} + \underset{\text{carbon dioxide}}{CO_2}$$

$$\underset{\text{lithium hydroxide}}{LiOH} + \underset{\text{hydrobromic acid}}{HBr} = \underset{\text{lithium bromide}}{LiBr} + \underset{\text{water}}{H_2O}.$$

It is also prepared by placing 300 grains of iron and 2 fluidounces of water in a flask, and adding gradually 1 oz. av. of bromine, shaking with the application of moderate heat until the mixture has acquired a green color and lost the odor of bromine; the solution of ferrous bromide is then filtered, heated, and 200 grains of lithium carbonate are added. The solution is filtered, and evaporated until the salt granulates.

$$\underset{\text{ferrous bromide}}{FeBr_2} + \underset{\text{lithium carbonate}}{Li_2CO_3} = \underset{\text{lithium bromide}}{2LiBr} + \underset{\text{ferrous carbonate}}{FeCO_3}$$

Description and Physical Properties—Lithium Bromide is a white, granular salt, odorless and having a sharp, slightly bitter taste; very deliquescent.

One Gm. of Lithium Bromide dissolves in 0.6 cc. of water at 25° C.; also in 0.4 cc. of boiling water; freely soluble in alcohol and soluble in ether.

Tests for Identity—An aqueous solution of the salt (1 in 20) is neutral or slightly alkaline to litmus.

At a low red heat the salt fuses, and at a higher heat it is slowly volatilized. It imparts a crimson color to a non-luminous flame.

Silver nitrate T.S., added to an aqueous solution of the salt (1 in 10) produces a yellowish white precipitate insoluble in nitric acid or in a moderate excess of ammonia water.

Tests for Purity—Add a few drops of ferric chloride T.S. and 1 cc. of chloroform to 10 cc. of an aqueous solution of the salt (1 in 20) and shake the mixture. The chloroform does not acquire a violet tint (*iodide*).

Drop 1 cc. of diluted sulphuric acid on about 1 Gm. of the powdered salt; no yellow color appears at once (*bromate*).

Dissolve about 0.1 Gm. of Lithium Bromide in 5 cc. of distilled water, add an excess of silver nitrate T.S. and a few drops of nitric acid; filter and wash the precipitate with distilled water, then digest it for ten minutes with 5 cc. of ammonium carbonate T.S. and filter. On supersaturating the filtrate with nitric acid, not more than a slight turbidity is produced at once (*chloride*).

Five cc. of an aqueous solution of the salt (1 in 100) acidulated with 4 drops of hydrochloric acid shows no immediate turbidity with 1 cc. of barium chloride T.S. (*sulphate*).

Add 5 cc. of hydrochloric acid and 5 cc. of chlorine T.S. to 0.4 Gm. of Lithium Bromide contained in a flat-bottomed flask of 50 cc. capacity, evaporate the mixture almost to dryness on a water bath, add 10 cc. of amyl alcohol and cautiously heat the mixture until the lower aqueous layer has evaporated. Then add three drops of hydrochloric acid and boil the solution for three minutes; the resulting insoluble residue, if any, when collected on a filter, washed with amyl alcohol and dried at 110° C., weighs not more than 0.002 Gm. (*other alkalies*). The removal of water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

Assay—Introduce into a tared weighing-bottle about 0.35 Gm. of Lithium Bromide, previously dried for twenty-four hours over sulphuric acid, stopper, weigh accurately, and proceed as directed under the Assay for bromides (see page 1515).

Each cc. of tenth-normal silver nitrate corresponds to 0.008686 Gm. of LiBr. Each Gm. of Lithium Bromide corresponds to not less than 97.9 cc. of tenth-normal silver nitrate.

This assay is explained on page 1462.

Preserve it in air-tight containers.

N. F. Preparations—Elixir Bromidorum Quinque, Syrupus Bromidorum.

Uses—Lithium bromide is used as a nerve sedative. Because of the low atomic weight of the metallic lithium, it contains a larger proportion of bromine than any other salt. The dose is fifteen grains (1 Gm.).

LITHII CARBONAS. N. F. Lithium Carbonate

(U. S. P. IX)

[Lith. Carb.]

Lithium Carbonate contains, when dried to constant weight at 100° C., not less than 98.5 per cent of Li_2CO_3 (73.89).

Preparation—Lithium carbonate may be prepared from lepidolite, one of the minerals in which it is found, in the following manner: 10 parts of finely powdered lepidolite, 10 parts of barium carbonate, 5 parts of barium sulphate, and 3 parts of potassium sulphate are fused at a very high temperature in a blast furnace. The heavy silicate and barium sulphate sink to the bottom, and a layer of potassium and lithium sulphate is found at the top of the fused mass. These can be extracted by simple lixiviation, and then the carbonate prepared by double decomposition with ammonium carbonate. It may also be prepared by treating a solution of ammonium carbonate, or of sodium carbonate, with a hot concentrated solution of lithium chloride. The reaction may be expressed by the equation

$$\underset{\text{lithium chloride}}{2LiCl} + \underset{\text{ammonium carbonate}}{(NH_4)_2CO_3} = \underset{\text{lithium carbonate}}{Li_2CO_3} + \underset{\text{ammonium chloride}}{2NH_4Cl}$$

Description and Physical Properties—Lithium Carbonate is a light, white powder, odorless, and having an alkaline taste; permanent in the air.

One Gm. of Lithium Carbonate dissolves in 78 cc. of water at 25° C.; also in 140 cc. of boiling water; almost insoluble in alcohol; dissolved by diluted acids with effervescence.

Tests for Identity—At a low red heat the salt fuses; at a higher temperature it loses some of its carbon dioxide, and is partially converted into lithium oxide. It imparts a crimson color to a non-luminous flame.

A saturated aqueous solution of the salt is alkaline to litmus.

Tests for Purity—Lithium Carbonate when dissolved in 40 parts of diluted acetic acid, leaves not more than 0.15 per cent of insoluble residue.

Mix 1 part of Lithium Carbonate with 20 parts of distilled water and add hydrochloric acid, drop by drop, with agitation until solution takes place. The resulting solution, after boiling and cooling, responds to the following tests when applied to separate portions:

The addition of ammonia water to 5 cc. of this solution until it has an alkaline reaction produces neither turbidity nor precipitation either before or after boiling (*iron, aluminum*).

Dilute another portion of 4 cc. of this solution with 6 cc. of distilled water; it does not respond to the test for heavy metals (see page 1519).

Add a slight excess of diluted hydrochloric acid to 0.2 Gm. of Lithium Carbonate contained in a flat-bottomed flask of 50 cc. capacity, evaporate the mixture almost to dryness on a water bath, add 10 cc. of amyl alcohol and cautiously heat the mixture until the lower aqueous layer has evaporated. Then add three drops of hydrochloric acid and boil the solution for three minutes. The resulting insoluble residue, if any, when collected on a filter, washed with amyl alcohol and dried at 110° C., weighs not more than 0.002 Gm. (*other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

Assay—Dissolve about 1.5 Gm. of Lithium Carbonate, previously dried to constant weight at 100° C. and accurately weighed, in 50 cc. of normal sulphuric acid and titrate the solution with normal potassium hydroxide, methyl orange T.S. being used as indicator.

Each cc. of normal sulphuric acid corresponds to 0.03694 Gm. of Li_2CO_3. Each Gm. of Lithium Carbonate, previously dried, corresponds to not less than 26.7 cc. of normal sulphuric acid.

This assay is explained on page 1458.

N. F. Preparation—Sal Potassii Bromidi Effervescens Compositum.

Uses—This salt is the source of the lithium salts, and it is prescribed in gout, in doses of five to fifteen grains (0.32 to 1 Gm.).

LITHII CITRAS. N.F. Lithium Citrate

(U. S. P. IX)

[Lith. Cit.]

Lithium Citrate contains not less than 98.5 per cent of $Li_3C_6H_5O_7.4H_2O$ (281.95).

Preparation—The process formerly official may be usefully employed in making this salt:

Take of lithium carbonate 100 grains; citric acid, in crystals, 200 grains; distilled water 2 fl. oz. Dissolve the citric acid in the water gently heated, and to the solution gradually add the lithium carbonate until perfectly dissolved, heating the solution so long as effervescence is produced. Evaporate, by means of a steam- or sand-bath, to a viscid consistence, dry the residue in an oven, at a temperature of about 115.5° C. (240° F.), then rapidly pulverize it, and preserve the powder in a well-stoppered bottle.

$$\underset{\text{lithium carbonate}}{3Li_2CO_3} + \underset{\text{citric acid}}{2H_3C_6H_5O_7} = \underset{\text{lithium citrate}}{2Li_3C_6H_5O_7} + \underset{\text{water}}{3H_2O} + \underset{\text{carbon dioxide}}{3CO_2}$$

Description and Physical Properties—Lithium Citrate occurs as a white powder, or in the granular form; odorless and having a cooling, faintly alkaline taste. It is deliquescent on exposure to moist air and loses its water of crystallization when heated to 150° C.

One Gm. of Lithium Citrate dissolves in 1.4 cc. of water at 25° C.; very slightly soluble in alcohol.

Tests for Identity—An aqueous solution of the salt (1 in 20) is faintly alkaline to litmus but is not reddened by one drop of phenolphthalein T.S.

At a red heat the salt chars, emits inflammable vapors having a pungent odor, and finally leaves a black residue of lithium carbonate mixed with carbon. It imparts a crimson color to a non-luminous flame.

Boil an aqueous solution of Lithium Citrate (1 in 20) with an equal volume of calcium chloride T.S.; a white precipitate forms.

Tests for Purity—Treat the residue obtained by igniting 0.4 Gm. of the salt at a red heat with a slight excess of diluted hydrochloric acid, filter, wash the residue with distilled water, evaporate the filtrate and washings almost to dryness on a water bath, in a flat-bottomed flask of 50 cc. capacity, add 10 cc. of amyl alcohol and cautiously heat the mixture until the lower aqueous layer has evaporated. Then add three drops of hydrochloric acid and boil the solution for three minutes. The resulting insoluble residue, if any, when collected on a filter, washed with amyl alcohol and dried at 110° C., weighs not more than 0.004 Gm. (*other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

Assay—Proceed as directed under the Assay for alkali salts of organic acids (see page 1514).

Each cc. of half-normal sulphuric acid corresponds to 0.04699 Gm. of $Li_3C_6H_5O_7.4H_2O$. Each Gm. of Lithium Citrate corresponds to not less than 21 cc. of half-normal sulphuric acid.

This assay is explained on page 1456.

Preserve it in air-tight containers.

N. F. Preparation—Sal Lithii Citratis Effervescens.

Uses—Lithium citrate is eliminated in the urine as a carbonate and may be used for the same purpose as lithium carbonate; it is more soluble than the latter. The dose is from five to twenty grains (0.32 to 1.3 Gm.).

SAL LITHII CITRATIS EFFERVESCENS. N.F. Effervescent Salt of Lithium Citrate

[Sal. Lith. Cit. Eff.]

	Metric	Alternative
Lithium Citrate	**50 Gm.**	1 oz. av.
Sodium Bicarbonate, dried and powdered	**570 Gm.**	11 oz. av. 175 gr.
Tartaric Acid, dried and powdered	**300 Gm.**	6 oz. av.
Citric Acid, unefflorescd crystals	**195 Gm.**	3 oz. av. 394 gr.
To make about	**1000 Gm.**	20 oz. av.

Prepare an effervescent salt as directed in the General Process (see page 475).

Uses—This salt forms a pleasant mode of administering a lithium salt; the dose is one to two drachms (4 to 8 Gm.).

LITHII SALICYLAS. N.F. Lithium Salicylate

[Lith. Salicyl.]

Lithium Salicylate contains, when dried to constant weight at 120° C., not less than 98.5 per cent of $LiC_7H_5O_3$ (144.02).

Preparation—This salt may be prepared by adding 60 grains of lithium carbonate to 1 fluidounce of distilled water and heating the mixture to boiling, then adding 220 grains of salicylic acid and continuing the heat until effervescence ceases, filtering, and evaporating. As in the case of sodium salicylate contact with metal should be avoided.

$$\underset{\text{lithium carbonate}}{Li_2CO_3} + \underset{\text{salicylic acid}}{2HC_7H_5O_3} = \underset{\text{lithium salicylate}}{2LiC_7H_5O_3} + \underset{\text{water}}{H_2O} + \underset{\text{carbon dioxide}}{CO_2}$$

Description and Physical Properties—Lithium Salicylate occurs as a white or grayish white powder; deliquescent in a moist atmosphere; odorless; taste sweetish.

It is very soluble in water and in alcohol.

Tests for Identity and Purity—When heated, the salt is decomposed, emitting the odor of phenol, and finally leaving a residue of lithium carbonate and carbon. It imparts a crimson color to a non-luminous flame.

An aqueous solution of the salt (1 in 20) is neutral or slightly acid to litmus, and when freshly made is colorless (*iron and organic coloring matter*); it does not effervesce upon the addition of diluted acids (*carbonate*).

Copper sulphate T.S. added to an aqueous solution of the salt (1 in 20) produces a bright green color.

Add a few drops of ferric chloride T.S. to an excess of an aqueous solution of the salt (1 in 4); a deep red color is produced. In a dilute solution of the salt (1 in 100) ferric chloride T.S. produces a deep violet-blue color.

Hydrochloric acid added to an aqueous solution of the salt (1 in 20) produces a voluminous white precipitate of salicylic acid.

Dissolve 0.7 Gm. of the salt in 10 cc. of distilled water, add an excess of hydrochloric acid and filter. Evaporate the filtrate almost to dryness on a water bath, in a 50 cc. Erlenmeyer flask, and then add 10 cc. of amyl alcohol and cautiously heat until the lower aqueous layer is evaporated; then add three drops of hydrochloric acid and boil the liquid for three minutes; the insoluble residue weighs not more than 0.005 Gm. (*other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

Dissolve 1 Gm. of the salt in 50 cc. of distilled water, precipitate the salicylic acid by the addition of a slight excess of hydrochloric acid and filter; the filtrate does not respond to the test for heavy metals (see page 1519).

Assay—Weigh accurately 1 Gm. of Lithium Salicylate, which has previously been dried for twenty-four hours over sulphuric acid, mix it with 2 Gm. of powdered ammonium sulphate in a porcelain crucible, and cautiously ignite it. The weight of the residue of lithium sulphate, multiplied by 2.629, represents its equivalent in Lithium Salicylate.

This assay is explained on page 1456.

Preserve it in well closed containers, protected from heat.

N. F. **Preparations**—Elixir Hydrangeæ et Lithii, Elixir Manacæ Compositum.

Uses—This salicylate is used, like sodium salicylate, for rheumatism and gout; it is given in doses of fifteen to forty grains (1 to 2.6 Gm.).

Unofficial Salts of Lithium

Lithii Borocitras Lithium Borocitrate	A white powder; soluble in water. It is used as an antarthritic in a dose of from 1 to 5 grains (0.06 to 0.32 Gm.)
Lithii Carbonas, Li_2CO_3 Lithium Carbonate	A light, white, alkaline powder; sparingly soluble in water. It is readily dissolved by acids with the evolution of carbon dioxide. It is used as an antilithic, diuretic, and antirheumatic. Dose, from 5 to 15 grains (0.32 to 1 Gm.)
Lithii Chloridum, LiCl Lithium Chloride	Colorless, deliquescent crystals; soluble in water, and having a sharp, saline taste. It is used for rheumatic and gouty conditions
Lithii Iodidum, LiI Lithium Iodide	A white, deliquescent coarse powder; very soluble in water. It is used as an antirheumatic and alterative. The dose is from 1 to 5 grains (0.32 to 1 Gm.)
Lithii Nitras, $LiNO_3$ Lithium Nitrate	Transparent crystals; very soluble in water. It is deliquescent and should be kept in well-stoppered bottles. Its uses and dose are similar to those for other lithium compounds
Lithii Phosphas, Li_3PO_4 Lithium Phosphate	A white, crystalline powder; very slightly soluble in water. It resembles the other lithium compounds in its medicinal uses. The dose is from 10 to 30 grains per day (0.6 to 2 Gm.)
Lithii Sulphas, $Li_2SO_4.H_2O$ Lithium Sulphate	Colorless crystals or a white crystalline powder; soluble in water. It is used for constipation with torpid liver or gravel. The dose is from 10 to 30 grains (0.6 to 2 Gm.)

CHAPTER XLIX

AMMONIUM

NH_4; 18.04

The ammonium salts resemble those of the alkali metals so closely in their physical and chemical properties that they are appropriately considered in this place.

The metal ammonium has not yet been isolated in the free state, so that its appearance cannot be described. An *ammonium amalgam* is known, however, and is made by dissolving potassium in mercury and adding a strong solution of ammonium chloride to it. It is a spongy, metallic appearing substance, which quickly decomposes into ammonia, mercury, and hydrogen upon exposure.

Tests for Ammonium Salts

Ammonium salts are decomposed by the addition of an excess of sodium hydroxide T.S. with the evolution of ammonia, recognizable by its odor and by its alkaline effect upon moistened red litmus paper, exposed to the vapor.

At high temperatures ammonium compounds are volatilized.

Ammonia darkens the blue color of paper moistened with solution of copper sulphate. Ammonia forms a white cloud with vapor of hydrochloric acid.

Solution of platinic chloride, with a few drops of hydrochloric acid, if added to a solution of an ammonium salt, produces a yellow precipitate.

Ammonium salts are mostly colorless, and generally very soluble in water.

Chloroplatinic acid gives with ammonium salts a yellow crystalline precipitate of ammonium chloroplatinate, only slightly soluble in water.

AQUA AMMONIÆ. U. S. Ammonia Water

[Aq. Ammon.]

Ammonia Water is an aqueous solution of ammonia (NH_3), containing not less than 9.5 per cent and not more than 10.5 per cent by weight of NH_3 (17.03). This solution deteriorates rapidly and must be assayed frequently.

Preparation—This useful liquid is rarely prepared by the pharmacist, for the reason that it can be made more economically by the manufacturer. A former official process directed that it be made by mixing and heating ammonium chloride with milk of lime in a retort, and collecting the distillate beneath the surface of distilled water contained in the receiver; the reaction was as follows:

$$\underset{\text{ammonium chloride}}{2NH_4Cl} + \underset{\text{calcium hydroxide}}{Ca(OH)_2} = \underset{\text{ammonia}}{2NH_3} + \underset{\text{calcium chloride}}{CaCl_2} + \underset{\text{water}}{2H_2O}$$

The manufacturer, however, rarely uses ammonium chloride; the sulphate is cheaper, and it is employed instead. Upon the large scale the ammonia liquor obtained from gas works is used directly as the source of ammonia, being mixed with milk of lime and heated; the gaseous ammonia is then passed through a series of tubes filled with charcoal, which retain the empyreumatic products. If the tubes are long enough, and sufficient charcoal is employed, a

pure product is assured; but much of the commercial ammonia water is empyreumatic through defective purification. Ammonia is also produced in enormous quantities by synthetic methods, either by the direct union of atmospheric nitrogen and hydrogen, by passing the mixture over a catalytic agent, at a temperature between 500° and 700° C., and under a pressure of two hundred atmospheres, or else from cyanamide, when it is decomposed by superheated steam as follows:

$$\underset{\text{calcium cyanamide}}{CaCN_2} + \underset{\text{steam}}{3H_2O} = \underset{\text{calcium carbonate}}{CaCO_3} + \underset{\text{ammonia}}{2NH_3}$$

Ammonia is also produced by destructively distilling waste animal matter.

Ammonia gas may be expelled from ammonia water by simply applying heat to the solution.

Description and Physical Properties—A colorless, transparent liquid, having a very pungent, characteristic odor.

Specific gravity: about 0.958 at 25° C.

Tests for Identity—Ammonia Water is strongly alkaline to litmus paper.

Dense, white fumes are produced on bringing a glass rod dipped into hydrochloric acid near the surface of the Ammonia Water. (This is due to the condensation in moist air of tiny particles of ammonium chloride.)

Tests for Purity—A 25 cc. portion of Ammonia Water, evaporated to dryness in a platinum or porcelain dish and dried to constant weight at 120° C., leaves not more than 0.005 Gm. of residue.

Add 0.1 cc. of tenth-normal potassium permanganate to 10 cc. of Ammonia Water to which a slight excess of diluted sulphuric acid has been added: the pink color is not completely destroyed within ten minutes (*oxidizable substances*).

When neutralized and then made slightly acid with hydrochloric acid, a 10 cc. portion of the Water meets the requirements of the test for *heavy metals*, page 1519.

Assay—Pour into a weighing bottle about 10 cc. of distilled water, tare the bottle and its contents, add about 5 cc. of Ammonia Water, and weigh accurately. Then titrate with normal sulphuric acid, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.01703 Gm. of NH_3.

This assay is explained on page 1455.

Preserve in a cool place in glass-stoppered or rubber-stoppered bottles made of hard glass, free from lead.

U. S. P. Preparations — Fluidextractum Senegæ; Spiritus Ammoniæ Aromaticus; Sulphur Lotum; Syrupus Senegæ.

N. F. Preparations—Elixir Ammoniæ Valeratis; Elixir Ferri Pyrophosphatis, Quininæ et Strychninæ; Linimentum Ammoniæ; Linimentum Opii Compositum; Linimentum Saponato-Camphoratum; Liquor Carmini; Liquor Ferri Citratis; Lotio Ammoniacalis Camphorata; Magma Bismuthi; Olea Infusa; Spiritus Ammonii Anisatus.

Uses—Ammonia water is occasionally employed hypodermically as a circulatory stimulant; it is also used for syncopal attacks by inhaling. It is rarely given by mouth, the aromatic spirit being preferred. The dose is ten to twenty minims (0.6 to 1.2 cc.), largely diluted. Externally, it is caustic and stimulating. It is a common ingredient in stimulating liniments. Pharmaceutically, ammonia water is frequently used to precipitate iron salts by combining with the acid radicals, ferric hydroxide being thrown down. Its advantage over the fixed alkalies consists in its volatility, any excess being readily detected by the odor. It is largely used for cleaning fabrics. The strength technically known as "Aqua Ammoniæ F. F. F.", or "20° ammonia", is employed most frequently in the arts; it may be diluted with water, according to the formula given on page 88, if it is desirable to make official ammonia water from it. In round numbers, three parts of 20° ammonia water requires two parts of water to reduce it to the strength of official ammonia water. This is one of the instances where the Baumé hydrometer degrees are still used commercially in designating the strength of liquids. In addition to the "20° ammonia", which represents about 17.5 per cent of NH_3, a "16° ammonia",

which corresponds to the official 10 per cent Ammonia water, and "26° ammonia", which represents the U. S. P. stronger ammonia water, are used technically and are commercial terms. The old name *spirits of hartshorn* is derived from an early origin of the product, as it was made by collecting the gases resulting from the destructive distillation of the horns of the variety of European deer known as the hart. This name is almost entirely supplanted by the modern name, "ammonia" which originated from the fact that *sal ammoniac* was obtained as a residue from the evaporation and decomposition of camels' urine in the hot sands of the Libyan Desert, near the temple of Ammon.

AQUA AMMONIÆ FORTIOR. U. S. Stronger Ammonia Water

[Aq. Ammon. Fort.]

Stronger Ammonia Water is an aqueous solution of ammonia (NH_3), containing not less than 27 per cent and not more than 29 per cent by weight of NH_3 (17.03). This solution deteriorates rapidly and must be assayed frequently.

Caution—Great care should be used in handling the liquid because of its caustic and irritating properties.

Preparation—Stronger ammonia water is prepared as already described under ammonia water, the only difference being that of relative strength.

Description and Physical Properties—A colorless, transparent liquid, having an excessively pungent, characteristic odor, and a very caustic and alkaline taste. *Stronger Ammonia Water must never be tasted nor smelled unless greatly diluted.*

Specific gravity: about 0.897 at 25° C.

Tests for Identity and Purity—Stronger Ammonia Water is strongly alkaline to litmus paper.

Stronger Ammonia Water diluted with twice its volume of distilled water conforms to the tests for identity and purity under *Aqua Ammoniæ*.

Assay—Pour into a weighing bottle about 25 cc. of distilled water, tare the bottle and its contents, add about 2 cc. of Stronger Ammonia Water, and weigh accurately. Then titrate with normal sulphuric acid, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.01703 Gm. of NH_3.

This assay is explained on page 1455.

Preserve in a cool place in partly filled, strong, glass-stoppered bottles made of hard glass, free from lead.

N. F. Preparations—Lotio Ammoniacalis Camphorata and the Petroxolins.

Uses—This liquid is used only for chemical and pharmaceutical purposes and for making ammonia water by dilution and in the preparation of the petroxolins of the N. F., where it forms an ammonium oleate, also in spirit of ammonia. It is too strong for internal administration.

SPIRITUS AMMONIÆ AROMATICUS. U. S. Aromatic Spirit of Ammonia

[Sp. Ammon. Arom.]

For the details of the formula see page 307.

Description and Physical Properties—A nearly colorless liquid when freshly prepared, but gradually acquiring a yellow color.

It has the taste of ammonia and an aromatic and pungent odor.

Specific gravity: about 0.900 at 25° C.

Preserve in glass-stoppered bottles, in a cool place.

Alcohol content, by volume, 62 to 68 per cent.

Uses—This is a very valuable and largely used antacid and stimulant. It is useful in cases of nausea, faintness, and other similar conditions. The dose is from twenty to sixty minims (1.2 to 4 cc.), largely diluted with water.

LIQUOR AMMONII ACETATIS. U. S. Solution of Ammonium Acetate

[Liq. Ammon. Acet.—Spirit of Mindererus]

Solution of Ammonium Acetate contains, in each 100 cc., not less than 6.5 Gm. and not more than 7.5 Gm. of $NH_4C_2H_3O_2$, with small amounts of acetic and carbonic acids.

Caution—Only a recently prepared Solution of Ammonium Acetate should be dispensed.

	Metric	Alternative
Ammonium Carbonate, in hard, translucent pieces	**5 Gm.**	183 gr.
Diluted Acetic Acid	**100 cc.**	8 oz. av.

Dissolve the ammonium carbonate in the diluted acetic acid without strong agitation.

Solution of Ammonium Acetate may also be prepared as follows:

Solution No. 1

	Metric	Alternative
Ammonium Carbonate, in hard, translucent pieces	**50 Gm.**	1 oz. av. 292 gr.
Distilled Water, a sufficient quantity,		
To make	**500 cc.**	1 pint

Solution No. 2

	Metric	Alternative
Acetic Acid	**160 cc.**	5 fl. oz. 60 min.
Distilled Water, a sufficient quantity,		
To make	**500 cc.**	1 pint

Cautiously mix the two solutions in equal volumes in a capacious vessel, in quantities sufficient to produce the amount of Solution of Ammonium Acetate needed.

The reaction involved in this process depends upon the decomposition of the ammonium carbonate with acetic acid; the free carbonic acid is a desirable addition to the solution, which should be dispensed in a slightly effervescent condition.

$$\underset{\text{acid ammonium carbonate and carbamate}}{NH_4HCO_3.NH_4NH_2CO_2} + \underset{\text{acetic acid}}{3HC_2H_3O_2} = \underset{\text{ammonium acetate}}{3NH_4C_2H_3O_2} + \underset{\text{carbon dioxide}}{2CO_2} + \underset{\text{water}}{H_2O}$$

It will be found in practice that the second formula is much more satisfactory than the first. The separate solutions keep well, and it is very convenient to mix them at the time of dispensing, and thus always be enabled to send out a fresh preparation, which retains sufficient carbonic acid to be agreeable to the patient.

Description and Physical Properties—A clear, colorless liquid, free from empyreumatic odor. It has a mildly saline, acidulous taste, and an acid reaction.

Test for Identity—Solution of Ammonium Acetate responds to the reactions for ammonium, page 649, and for acetates, page 800.

Test for Purity—Not more than 0.003 Gm. of ash remains on evaporating 20 cc. of the Solution and igniting the residue.

Assay—Transfer 25 cc. of Solution of Ammonium Acetate to a distilling flask, dilute with 100 cc. of distilled water, add 25 cc. of 10 per cent sodium hydroxide solution, and distil the liquid until all of the ammonia has been driven over (about 100 cc. of distillate), receiving the distillate under the surface of 50 cc. of normal sulphuric acid contained in a flask. Titrate the excess of acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.07707 Gm. of $NH_4C_2H_3O_2$.

This assay is explained on page 1457.

U. S. P. Preparation—Liquor Ferri et Ammonii Acetatis.

History—Ramond Minderer was one of the most famous physicians of his time which was early in the seventeenth century. He lived in Augsburg, Germany, and was medical adviser to the Fuggers, the great international financiers of the period. He devised the preparation which bears his name today and first prepared it from vinegar and hartshorn.

Uses—This solution is used as a diaphoretic and diuretic, in the dose of half a fluidounce (15 cc.).

AMMONII BENZOAS. U. S. Ammonium Benzoate
[Ammon. Benz.]

Ammonium Benzoate, when dried for twenty-four hours over sulphuric acid, contains not less than 98 per cent of $NH_4C_7H_5O_2$ (139.12).

Preparation—This salt may be advantageously prepared by a former official process, which is as follows:

Take of benzoic acid 480 gr.; ammonia water, 3½ fl. oz., or a sufficient quantity; distilled water, 4 fl. oz. Dissolve the acid in 3½ fl. oz. of the ammonia water, previously mixed with the distilled water; evaporate with a gentle heat, occasionally adding ammonia water, if necessary, to maintain a slight excess of the alkali; then set aside to crystallize, and dry the crystals without heat.

The process is one of direct combination, the reaction being as follows:

$$\underset{\text{benzoic acid}}{HC_7H_5O_2} + \underset{\text{ammonia water}}{NH_4OH} = \underset{\text{ammonium benzoate}}{NH_4C_7H_5O_2} + \underset{\text{water}}{H_2O}$$

The object of retaining an excess of alkali in the process is to prevent the formation of the acid benzoate, which is less soluble than the official salt.

Description and Physical Properties—Thin, white, laminar crystals, or a crystalline powder, gradually losing ammonia on exposure to air. It is odorless, or has a slight odor of benzoic acid.

One Gm. of Ammonium Benzoate is soluble in 10 cc. of water, 35.5 cc. of alcohol, and in 8 cc. of glycerin, at 25° C.

Tests for Identity—When Ammonium Benzoate is heated to about 200° C., ammonia and benzoic acid are given off.

An aqueous solution of Ammonium Benzoate (1 in 10) responds to the reactions for ammonium, page 649, and for benzoates, page 832.

Tests for Purity—An aqueous solution of the salt (1 in 20) is neutral or not more than slightly acid to litmus paper. Ash: not more than 0.05 per cent.

Acidulate 10 cc. of an aqueous solution of the salt (1 in 50) with hydrochloric acid, and filter: the filtrate meets the requirements of the test for *heavy metals*, page 1519.

Assay—Dry about 0.5 Gm. of Ammonium Benzoate for twenty-four hours over sulphuric acid, weigh accurately, and dissolve in 10 cc. of distilled water in a separator. Add to the solution 5 cc. of diluted sulphuric acid, and extract the liberated benzoic acid by shaking out with three successive portions of 25, 15 and 10 cc., respectively, of chloroform, passing the chloroform solution through a filter previously moistened with chloroform, and removing any benzoic acid adhering to the stem of the funnel and filter paper with a few cc. of chloroform. Evaporate the chloroform solution at a temperature not above 40° C. to about 5 cc., add 25 cc. of a mixture of equal volumes of neutralized alcohol and distilled water, and titrate this solution with tenth-normal barium hydroxide, using phenolphthalein T.S. as indicator. Each cc. of tenth-normal barium hydroxide corresponds to 0.01391 Gm. of $NH_4C_7H_5O_2$.

This assay is explained on page 1456.

Preserve in well-closed containers, in a cool place.

Uses—Ammonium benzoate is used as a urinary antiseptic, in doses of five to twenty grains (0.32 to 1.3 Gm.).

AMMONII BROMIDUM. U. S. Ammonium Bromide

[Ammon. Brom.]

Ammonium Bromide, when dried for twenty-four hours over sulphuric acid, contains not less than 98.5 per cent of NH_4Br (97.96).

Preparation—Several methods have been employed in making this salt; 1. By double decomposition between hot, concentrated solutions of ammonium sulphate and potassium bromide. Most of the potassium sulphate separates out as the mixture cools, leaving ammonium bromide in solution. Alcohol is usually added to facilitate this separation. 2. By adding ammonia water to a solution of ferrous bromide and removing the precipitate of ferrous hydroxide. 3. By the gradual addition of ammonia water to a supersaturated aqueous solution of bromine. When all of the ammonia water is added and the solution is free from the odor of bromine, it is evaporated and the salt granulated. The reaction may be expressed as follows:

$$\underset{\text{bromine}}{6Br} + \underset{\text{ammonia}}{8NH_3} = \underset{\text{ammonium bromide}}{6NH_4Br} + \underset{\text{nitrogen}}{N_2}$$

It may also be made by the action of hydrobromic acid on ammonium hydroxide and subsequent crystallization.

$$\underset{\substack{\text{ammonia}\\\text{water}}}{NH_4OH} + \underset{\substack{\text{hydrobromic}\\\text{acid}}}{HBr} = \underset{\substack{\text{ammonium}\\\text{bromide}}}{NH_4Br} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—Colorless crystals, or a white, crystalline or granular powder, having no odor. It is somewhat hygroscopic.

One Gm. of Ammonium Bromide is soluble in 1.3 cc. of water and in 12 cc. of alcohol, at 25° C. One Gm. is soluble in 0.9 cc. of boiling water and in 1.2 cc. of boiling alcohol.

Tests for Identity—When heated, Ammonium Bromide volatilizes without fusing.

An aqueous solution of the salt (1 in 10) responds to the reactions for ammonium, page 649, and for bromides, page 574.

Tests for Purity—An aqueous solution of the salt (1 in 20) is neutral or not more than slightly acid to litmus paper.

Add 2 cc. of nitric acid to about 2 Gm. of Ammonium Bromide, evaporate the mixture to dryness in a porcelain dish on a water bath, and ignite: not more than 0.05 per cent of residue remains.

Add a few drops of ferric chloride T.S. and 1 cc. of chloroform to 10 cc. of an aqueous solution of the salt (1 in 20) and shake the mixture: the chloroform does not acquire a violet tint (*iodide*).

Drop 1 cc. of diluted sulphuric acid upon about 1 Gm. of the powdered salt: no yellow color appears at once (*bromate*).

A blue color is not immediately produced on adding potassium ferrocyanide T.S. to 20 cc. of an aqueous solution of the salt (1 in 250) (*iron*).

Add 1 cc. of potassium sulphate T.S. to 10 cc. of an aqueous solution of Ammonium Bromide (1 in 20) acidulated with hydrochloric acid: no turbidity is produced immediately (*barium*). The addition of barium chloride T.S. to a similar solution of the salt acidulated with hydrochloric acid produces no turbidity (*sulphate*).

An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page 1519.

Assay—Proceed as directed under the assay for bromides, page 1515, using about 0.4 Gm. of Ammonium Bromide, previously dried for twenty-four hours over sulphuric acid, and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.009796 Gm. of NH_4Br. Each Gm. of Ammonium Bromide, previously dried, corresponds to not less than 100.5 cc. and not more than 103.4 cc. of tenth-normal silver nitrate.

This assay is explained on page 1462.

Preserve in well-closed containers.

N. F. Preparations—Elixir Ammonii Bromidi; Elixir Bromidorum Quinque; Elixir Bromidorum Trium; Syrupus Bromidorum; Syrupus Thymi Compositus.

Uses—Ammonium bromide is sometimes preferred to potassium bromide as a hypnotic and sedative. The dose is from ten to sixty grains (0.65 to 4 Gm.).

AMMONII CARBONAS. U. S. Ammonium Carbonate

[Ammon. Carb.]

Ammonium Carbonate consists of acid ammonium carbonate [$NH_4HCO_3 = 79.03$] and ammonium carbamate [$NH_4NH_2CO_2 = 78.07$] in varying proportions, and yields not less than 30 per cent and not more than 32 per cent of NH_3 (17.03).

Preparation—The large consumption of this salt of ammonium has led to several methods of preparation. The one which is most used at present is the dry sublimation of ammonium sulphate with chalk or calcium carbonate; by double decomposition calcium sulphate and ammonium carbonate are produced.

$$\underset{\text{ammonium sulphate}}{2(NH_4)_2SO_4} + \underset{\text{calcium carbonate}}{2CaCO_3} = \underset{\text{acid ammonium carbonate and carbamate (official)}}{NH_4HCO_3.NH_4NH_2CO_2} + \underset{\text{water}}{H_2O} + \underset{\text{ammonia}}{NH_3} + \underset{\text{calcium sulphate}}{2CaSO_4}$$

The advantage claimed for the use of ammonium sulphate over ammonium chloride is simply that of greater economy.

Official ammonium carbonate is, chemically, a mixed salt. It consists approximately of one molecule of acid ammonium carbonate or bicarbonate, and one of ammonium carbamate, the latter may be regarded as ammonium carbonate minus a molecule of water. If ammonium carbamate is dissolved in water, it is soon changed to normal ammonium carbonate.

$$\underset{\text{ammonium carbamate}}{NH_4NH_2CO_2} + \underset{\text{water}}{H_2O} = \underset{\text{normal ammonium carbonate}}{(NH_4)_2CO_3}$$

Hence an aqueous solution of commercial ammonium carbonate contains both the neutral and acid carbonates. If the official ammonium carbonate is exposed to the air, it is soon changed into the acid carbonate or bicarbonate, through loss of ammonia, and it is thus depreciated in quality. The bicarbonate may be converted back into the carbonate by treating it with ammonia water. This fact is officially recognized in the preparation of aromatic spirit of ammonia. The reaction is as follows:

$$\underset{\text{ammonium bicarbonate}}{NH_4HCO_3} + \underset{\text{ammonia}}{NH_3} = \underset{\text{normal ammonium carbonate}}{(NH_4)_2CO_3}$$

The principal impurities in the commercial salt are empyreumatic substances; the U. S. P. test excludes these.

Description and Physical Properties—White, hard, translucent, columnar masses, having a strong odor of ammonia, without empyreuma, and a sharp, ammoniacal taste. On exposure to the air, the salt loses both ammonia and carbon dioxide, becoming opaque, and is finally converted into friable, porous lumps, or a white powder. For medicinal purposes, use only the translucent portions.

One Gm. of Ammonium Carbonate is very slowly soluble in 4 cc. of water at 25° C. It is decomposed by hot water, with the evolution of carbon dioxide and ammonia. By prolonged boiling with water, the salt is completely decomposed and volatilized. Alcohol dissolves the carbamate, leaving the acid carbonate.

Tests for Identity—When heated, Ammonium Carbonate is volatilized without charring, the vapor being strongly alkaline to moistened litmus paper.

An aqueous solution of the salt (1 in 20) effervesces with acids, and is alkaline to litmus paper.

Tests for Purity—When heated until volatilized, not more than 0.05 per cent of residue remains.

An aqueous solution of the salt (1 in 50) to which a slight excess of hydrochloric acid has been added meets the requirements of the test for *heavy metals*, page 1519.

A 10 cc. portion of an aqueous solution of the salt (1 in 20), on the addition of a slight excess of silver nitrate T.S., followed by a slight excess of nitric acid, does not assume a brown color (*thiosulphate*).

A 2 Gm. portion of the salt shows no more *chloride* than corresponds to 0.1 cc. of fiftieth-normal hydrochloric acid, page 1556, and no more *sulphate* than corresponds to 0.1 cc. of fiftieth-normal sulphuric acid, page 1567.

Add a slight excess of nitric acid to an aqueous solution containing 1 Gm. of the salt, and evaporate to dryness on a water bath: a colorless, odorless residue is obtained (*empyreumatic matter*).

Assay—Place in a weighing bottle about 10 cc. of distilled water, tare the bottle and its contents, add about 2 Gm. of unaltered, translucent Ammonium Carbonate, and weigh accurately. Transfer the contents of the bottle to a 200 cc. flask, add 50 cc. of normal sulphuric acid, and, when solution is effected, titrate the excess of acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.01703 Gm. of NH_3.

This assay is explained on page 1455.

Preserve in well-closed containers, in a cool place.

U. S. P. Preparations—Liquor Ammonii Acetatis; Spiritus Ammoniæ Aromaticus.

N. F. Preparations—Liquor Ferri Salicylatis; Magma Bismuthi; Mistura Pectoralis, Stokes'.

Uses—Ammonium carbonate is given hypodermically as a circulatory stimulant. By mouth it is used as an expectorant, especially for children. It is the basis of "smelling salts" so valuable as a restorative in hysterical syncope (see page 1232). The dose is three to five grains (0.2 to 0.32 Gm.). It is generally administered in mucilaginous syrups. It is occasionally used as a leavening agent and in consequence is sometimes called "bakers' ammonia".

AMMONII CHLORIDUM. U. S. Ammonium Chloride
[Ammon. Chlor.]

Ammonium Chloride, when dried for twenty-four hours over sulphuric acid, contains not less than 99.5 per cent of NH_4Cl (53.50).

Preparation—*Sal ammoniac*, as it is termed commercially, is chiefly made from *gas liquor*, the ammoniacal liquid obtained from gas works during the destructive distillation of coal. The ammonia is generally neutralized with hydrochloric acid, the solution evaporated, and the dry mass sublimed in iron pots. The tough, fibrous sublimate is fitted for pharmaceutical and medicinal purposes by purification. It nearly always contains traces of iron, due to the contact of the salt with the cast iron dome. This may be separated by treatment with ammonia water by the following process of purification:

Purification of Commercial Ammonium Chloride—Take of commercial ammonium chloride, in small pieces, 22 oz. av.; ammonia water, 5 fl. dr.; water, 2 pints. Dissolve the ammonium chloride in the water, in a porcelain dish, with the aid of heat; add the ammonia water, and continue the heat for a short time; filter the solution while hot, and evaporate to dryness, with constant stirring, at a moderate heat, until it granulates; the ferrous or ferric chloride is converted into insoluble ferric hydroxide, which is filtered out. If the amount of ammonia water specified is not sufficient to precipitate all of the iron, more must be added.

Description and Physical Properties—A white, crystalline or granular powder, without odor, and having a cooling, saline taste. It is somewhat hygroscopic.

One Gm. of Ammonium Chloride is soluble in 2.6 cc. of water, 100 cc. of alcohol, and in 8 cc. of glycerin, at 25° C. One Gm. is soluble in 1.4 cc. of boiling water.

Tests for Identity—Ammonium Chloride on ignition is volatilized without fusing.

An aqueous solution of the salt (1 in 10) responds to the reactions for ammonium, page 649, and for chlorides, page 567.

Tests for Purity—An aqueous solution of the salt (1 in 20) does not show an immediate acid reaction with 1 drop of methyl orange T.S.

An aqueous solution of Ammonium Chloride meets the requirements of the test for *heavy metals*, page 1519.

Acidulate 10 cc. of an aqueous solution of the salt (1 in 10) with hydrochloric acid and add a few drops of ferric chloride T.S.: no red color should be produced (*thiocyanate*).

Add 2 cc. of nitric acid to 2 Gm. of the salt, and evaporate the mixture to dryness in a porcelain dish on a water bath: a white residue is obtained which, when ignited, yields not more than 0.1 per cent of *non-volatile substances*.

Assay—Proceed as directed under the assay for chlorides, page 1514, using about 0.2 Gm. of Ammonium Chloride, previously dried for twenty-four hours over sulphuric acid and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.005350 Gm. of NH_4Cl.

This assay is explained on page 1463.

U. S. P. Preparation—Trochisci Ammonii Chloridi.

History—This salt is mentioned by Pliny under the name of *Hammoniacus Sal*. He said that it received its name from being found as a residue from the natural evaporation of camel urine in the hot sands of the Libyan Desert near the temple of Ammon. Later it was found to be prepared by the Arabs by sublimation from the soot which resulted from burning camel's dung.

Uses—Ammonium chloride is used chiefly as an expectorant in bronchitis. It is occasionally employed in digestive diseases. The dose is from five to ten grains (0.32 to 0.65 Gm.). It is sometimes used as an inhalation in catarrh, after drawing the vapors of hydrochloric acid and ammonia into a bottle, where they combine to form ammonium chloride in colloidal ærial suspension. It should never be combined with potassium chlorate, particularly in compressed tablets; for, although the combination is often desirable from a therapeutic standpoint, in time the tablets explode and serious results have been experienced. The crude form of this salt, *sal ammoniac*, is used largely in solution as an electrolyte for voltaic batteries.

AMMONII SALICYLAS. U. S. Ammonium Salicylate

[Ammon. Salicyl.]

Ammonium Salicylate, when dried for twenty-four hours over sulphuric acid, contains not less than 98 per cent of $NH_4C_7H_5O_3$ (155.12).

Preparation—This salt may be made by adding salicylic acid to ammonia water until nearly saturated, evaporating the solution, crystallizing, and purifying the product by recrystallization.

$$\underset{\text{ammonia water}}{NH_4OH} + \underset{\text{salicylic acid}}{HC_7H_5O_3} = \underset{\text{ammonium salicylate}}{NH_4C_7H_5O_3} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—Colorless, lustrous, monoclinic prisms, or plates, or a white, crystalline powder. It is odorless, and has at first a slightly saline, bitter taste, with a sweetish after-taste. It is stable in dry air.

One Gm. of Ammonium Salicylate is soluble in 1 cc. of water and in 3 cc. of alcohol, at 25° C.

Tests for Identity—When heated, Ammonium Salicylate fuses with decomposition, giving off inflammable vapors and the odor of phenol, and is finally volatilized.

Ammonium Salicylate responds to the reactions for ammonium, page 649, and for salicylates, page 826.

Tests for Purity—An aqueous solution of the salt (1 in 10) is colorless and neutral or slightly acid to litmus paper.

Ash: not more than 0.1 per cent.

Acidulate 10 cc. of an aqueous solution of Ammonium Salicylate (1 in 50) with hydrochloric acid, and filter: the filtrate meets the requirements of the test for *heavy metals*, page 1519.

Assay—Dry about 0.5 Gm. of Ammonium Salicylate over sulphuric acid, weigh accurately, and dissolve in 10 cc. of distilled water in a separatory funnel. Add to the solution 5 cc. of diluted sulphuric acid, and extract the liberated salicylic acid by shaking out with three successive portions of 25, 15 and 10 cc., respectively, of chloroform, passing the chloroform solutions through a filter previously moistened with chloroform and removing any salicylic acid adhering to the stem of the funnel and filter paper with a few cc. of chloroform. Evaporate the chloroform solution to about 5 cc., add 25 cc. of a mixture of equal volumes of neutralized alcohol and distilled water, phenolphthalein T.S. being used as indicator, and titrate this solution with tenth-normal barium hydroxide. Each cc. of tenth-normal barium hydroxide corresponds to 0.01551 Gm. of $NH_4C_7H_5O_3$.

This assay is explained on page 1456.

Preserve in well-closed containers, protected from heat and light.

Uses—Ammonium salicylate is preferred to sodium salicylate by many physicians; it is used in gout and rheumatism in doses of three to eight grains (0.2 to 0.5 Gm.).

AMMONII HYPOPHOSPHIS. N. F. Ammonium Hypophosphite
[Ammon. Hypophos.]

Ammonium hypophosphite contains, when dried over sulphuric acid for 24 hours, not less than 97.5 per cent of $NH_4PH_2O_2$ (83.10).

Preparation—It may be prepared by neutralizing hypophosphorous acid with ammonia, concentrating and crystallizing. The reaction is explained by the following equation:

$$\underset{\text{ammonia}}{NH_3} + \underset{\text{hypophosphorous acid}}{HH_2PO_2} = \underset{\text{ammonium hypophosphite}}{NH_4H_2PO_2}$$

Description and Physical Properties—Ammonium Hypophosphite occurs in deliquescent, colorless, hexagonal plates, or as a granular powder, odorless and having a saline and bitter taste.

One Gm. dissolves in about 1 cc. of water, and in about 20 cc. of alcohol at 25° C.; very soluble in boiling water or boiling alcohol.

Tests for Identity—When heated, the salt is decomposed with the evolution of hydrogen phosphide, which is spontaneously inflammable.

An aqueous solution of the salt (1 in 20) is neutral or slightly acid to litmus and when heated with sodium hydroxide gives off ammonia.

An aqueous solution of the salt (1 in 20) slightly acidulated with sulphuric acid, yields with silver nitrate T.S. a white precipitate, which rapidly turns brown or black through the separation of metallic silver. A similar portion of the solution, slightly acidulated with sulphuric acid, yields, on heating with copper sulphate T.S. a reddish brown precipitate.

Tests for Purity—Ten cc. of an aqueous solution of the salt (1 in 20) remains clear for five minutes after the addition of 5 cc. of ammonium oxalate T.S. and a few drops of ammonia water (*calcium salt*).

Add 1 cc. of calcium chloride T.S. to 10 cc. of the aqueous solution of the salt (1 in 20) previously acidulated with 1 cc. of acetic acid; no turbidity is produced (*oxalate*).

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

Boil 5 cc. of an aqueous solution of the salt (1 in 25) with 3 cc. of sodium hydroxide solution until the ammonia is expelled, add 5 cc. of nitric acid, and evaporate to dryness on a water bath; the residue meets the requirements of the test for arsenic (see page 1512).

Assay—Dissolve about 0.2 Gm. of Ammonium Hypophosphite, previously dried over sulphuric acid for 24 hours and accurately weighed, in 10 cc. of distilled water, add 3 cc. of sodium hydroxide T.S. and boil until the ammonia is expelled. Then add 5 cc. of nitric acid and evaporate the solution to dryness on a water bath. Add 1 cc. of nitric acid and again evaporate it to dryness on a water bath. Dissolve the residue in 20 cc. of distilled water, transfer it to a 200 cc. graduated flask, add a drop of phenolphthalein T.S. and sufficient sodium hydroxide T.S. (free from chlorine) to produce a pink color, and then add 100 cc. of tenth-normal silver nitrate and agitate well. Now gradually add zinc oxide (free from chloride) in small portions until the liquid is neutral to litmus, and then sufficient distilled water to make the mixture measure 200 cc. Agitate the mixture thoroughly, filter it through a dry filter and collect 100 cc. of the filtrate (representing one-half of the Ammonium Hypophosphite taken). Add to this 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate to the production of a permanent red color.

Each cc. of tenth-normal silver nitrate used corresponds to 0.00277 Gm. of $NH_4PH_2O_2$. Each gram of Ammonium Hypophosphite corresponds to not less than 352.0 cc. of tenth-normal silver nitrate.

This assay is explained on page 1464.

Preserve it in well-closed containers.

N. F. Preparation—Syrupus Ammonii Hypophosphitis.

Uses—It is used as an alterative in doses of three grains (0.2 Gm.).

AMMONII PHOSPHAS. N. F. Ammonium Phosphate
[Ammon. Phos.]

Ammonium phosphate contains diammonium hydrogen phosphate ($(NH_4)_2HPO_4$ = 132.13) and ammonium dihydrogen phosphate ($NH_4H_2PO_4$ = 115.09), corresponding to not less than 22 per cent of combined ammonia (NH_3 = 17.03).

Preparation—It is made by evaporating a solution prepared by adding an excess of ammonia to phosphoric acid.

The reaction is explained by the following equation:

$$\underset{\text{ammonia}}{2(NH_3)} + \underset{\text{phosphoric acid}}{H_3PO_4} = \underset{\text{diammonium phosphate}}{(NH_4)_2HPO_4}$$

Description and Physical Properties—Ammonium Phosphate occurs in colorless crystals or as a white crystalline powder, losing ammonia on exposure to the air.

One Gm. dissolves in about 4 cc. of water; it is insoluble in alcohol. The aqueous solution (1 in 20) is neutral or alkaline to litmus.

Tests for Identity—Separate portions of an aqueous solution of the salt (1 in 20) yield with magnesia mixture T.S. a white precipitate, with silver nitrate T.S. a yellow precipitate, and, upon warming with ammonium molybdate T.S., a yellow precipitate.

Tests for Purity—Dissolve 1 Gm. of Ammonium Phosphate in 20 cc. of distilled water; the resulting solution is not more than slightly turbid (*calcium, aluminum*).

Ten cc. of an aqueous solution of the salt (1 in 100) acidulated with nitric acid, is not rendered more than slightly opalescent by silver nitrate T.S. (*chloride*).

Ten cc. of an aqueous solution of Ammonium Phosphate (1 in 100), mixed with 2 cc. of hydrochloric acid, is not rendered turbid at once by the addition of a few drops of barium chloride T.S. (*sulphate*).

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

Five cc. of a solution of Ammonium Phosphate in diluted nitric acid (1 in 25), heated with 1 cc. of sulphuric acid until fumes of sulphur trioxide appear, meets the requirements of the test for arsenic (see page 1512).

Assay—Transfer about 1 Gm. of Ammonium Phosphate, accurately weighed, to a distilling flask, dissolve it in 200 cc. of distilled water and add 25 cc. of an aqueous solution of sodium hydroxide (1 in 4). Connect the flask with a small glass condenser, the lower outlet tube of which is inserted beneath the surface of 50 cc. of half-normal sulphuric acid, contained in a flask of about 500 cc. capacity and distil the liberated ammonia into the acid. Titrate the excess of acid with half-normal sodium hydroxide, using methyl orange T.S. as an indicator, and calculate the percentage of ammonia in the salt.

Each cc. of half-normal sulphuric acid corresponds to 0.008515 Gm. of NH_3. Each Gm. of Ammonium Phosphate corresponds to not less than 23.5 cc. of half-normal sulphuric acid.

This assay is explained on page 1457.

Preserve it in well-closed containers in a cool place.

N. F. Preparation—Liquor Phosphatum Compositus.

Uses—It is almost never prescribed except as an ingredient of the solution of phosphates. Dose, five grains (0.3 Gm.).

AMMONII VALERAS. N. F. Ammonium Valerate

(U. S. P. IX)

[**Ammon. Valer.**—Ammonium Valerianate]

Ammonium valerate is a compound of ammonia with valeric acid, having a somewhat varying composition.

Preparation—This valerate, formerly called valerianate, may be prepared by passing dried gaseous ammonia into monohydrated valeric acid.

The salt which is found in commerce is usually the acid salt; hence, in making a solution of it, as in the process for elixir of ammonium valerate, the excess of acid should be neutralized by the addition of sufficient ammonia water.

Description and Physical Properties—Ammonium Valerate occurs in colorless, or white, quadrangular plates, emitting the odor of valeric acid; it is deliquescent in moist air, and has a sharp and sweetish taste.

One Gm. of Ammonium Valerate dissolves in 0.3 cc. of water and in 0.6 cc. of alcohol at 25° C.; soluble in ether.

Tests for Identity—When heated, the salt fuses, gives off vapors of ammonia and valeric acid, and is finally volatilized, leaving not more than 0.05 per cent of residue.

An aqueous solution of the salt (1 in 20) is acid to litmus and when heated with potassium hydroxide T.S. evolves ammonia.

Supersaturate slightly a concentrated aqueous solution of Ammonium Valerate with sulphuric acid; an oily layer of valeric acid rises to the surface.

Tests for Purity—Precipitate completely 10 cc. of an aqueous solution of the salt (1 in 20) with ferric chloride T.S.; the filtrate does not possess a deep red color (*acetate*).

An aqueous solution of the salt (1 in 50), when slightly acidulated with hydrochloric acid and filtered through a small, wetted filter, does not respond to the test for heavy metals (see page 1519).

Preserve it in well-closed containers.

N. F. Preparation—Elixir Ammonii Valeratis.

Uses—Ammonium valerate is used in hysteria, neuralgia, and similar diseases as a nervine, in doses of 2 to 20 grains (0.14 to 1.3 Gm.).

Unofficial Salts of Ammonium

Ammonii Arsenas, $(NH_4)_2HAsO_4$ Ammonium Arsenate	A poisonous, white, crystalline powder; soluble in water. It is used as an alterative, chiefly in skin diseases. Dose, $\frac{1}{20}$ grain (0.003 Gm.)
Ammonii Bicarbonas, NH_4HCO_3 Ammonium Bicarbonate	Large, white crystals; soluble in water; easily decomposed by heat. It is used in the production of other ammonium salts and as an antacid and stimulant. Dose, 5 to 15 grains (0.3 to 1 Gm.)

Unofficial Salts of Ammonium—*Continued*

Ammonii Boras, $(NH_4HB_4O_7)+3H_2O$ Ammonium Borate	White crystals, soluble in water. Ammonium borate is employed in renal colic and in chronic cystitis. Dose, 10 to 20 grains (0.6 to 1.2 Gm.)
Ammonii Citras, $(NH_4)_3C_6H_5O_7+3H_2O$ Ammonium Citrate	A white powder; readily soluble in water. It is unstable in air and therefore should be kept well-stoppered. It is used as a diaphoretic, antipyretic and diuretic
Ammonii Dichromas, $(NH_4)_2Cr_2O_7$ Ammonium Dichromate	Orange crystals; soluble in water. When strongly heated it decomposes leaving a residue of chromium sesquioxide. It is used chiefly as a chemical reagent
Ammonii et Ferri Chloridum Ammonium and Iron Chloride	A reddish-yellow powder; soluble in water. It is used as an aperient and chalybeate, and should be kept well stoppered. Dose, 4 to 12 grains (0.25 to 0.7 Gm.)
Ammonii et Potassii Tartras, $NH_4KC_4H_4O_6$ Ammonium and Potassium Tartrate	A white, crystalline powder; soluble in water. It is used as a cathartic
Ammonii Formas, NH_4CHO_2 Ammonium Formate	Transparent, colorless crystals having a cooling pungent taste. It is used in chronic paralysis and palsy of sensation or motion. Dose, 5 grains (0.3 Gm.)
Ammonii Fluoridum, NH_4F Ammonium Fluoride	White crystals; soluble in cold water. It is used in the manufacture of other fluorides and as a reagent in analytical chemistry
Ammonii Iodidum, NH_4I (U. S. P. IX) Ammonium Iodide	A white, granular powder; hygroscopic and very soluble in water. On exposure to air and light it becomes yellow or yellowish brown due to the loss of ammonia and the separation of free iodine. It is used as a resolvent and alterative, similar to potassium iodide. The dose is from 3 to 5 grains (0.2 to 0.3 Gm.)
Ammonii Nitras, NH_4NO_3 Ammonium Nitrate	Colorless crystals; soluble in water. Used in pyrotechnics, explosives, fertilizers and in the manufacture of "laughing gas"
Ammonii Nitris, NH_4NO_2 Ammonium Nitrite	A clear, yellow liquid; soluble in water and decomposed by heat, yielding water and nitrogen. It is used in the laboratory preparation of nitrogen
Ammonii Sulphas, $(NH_4)_2SO_4$ Ammonium Sulphate	Colorless, transparent crystals, when pure. It is readily soluble in water. It is chiefly used as a source of ammonia and as a fertilizer
Ammonii Sulphis, $(NH_4)_2SO_3$ Ammonium Sulphite	Colorless, deliquescent crystals, having an acrid and sulphurous taste. Very soluble in water. Used in fermentative dyspepsia and in skin diseases. Dose, 5 to 20 grains (0.3 to 1.2 Gm.)
Ammonii Sulphocyanidum, NH_4CNS Ammonium Sulphocyanide	Colorless, deliquescent crystals, very soluble in water. It is chiefly used as a chemical reagent, especially in the detection of ferric iron
Ammonii Valeras (U. S. P. IX) Ammonium Valerate	Colorless, deliquescent plates, having a valerian-like odor. It is very soluble in water. It is used as a nerve tonic. The dose is from 2 to 8 grains (0.12 to 0.5 Gm.)

CHAPTER L

MAGNESIUM, CALCIUM, RADIUM, BARIUM, AND STRONTIUM

Mg; 24.32 Ca; 40.07 Ra; 226.00 Ba; 137.37 Sr; 87.63

The compounds of these metals form a natural group. They have numerous physical and chemical characteristics in common. Barium is represented in the U. S. P. by only one compound, the insoluble sulphate, used in X-ray work. The soluble salts are too toxic for use in medicine. Strontium salts were first admitted to the U. S. P. 1890, and have limited use. Magnesium was formerly classed with the alkali earths, but it is now usually separated from them, because of its closer chemical analogies to zinc. It is so closely allied to the alkali earths in its pharmaceutical and medical aspects that it is more convenient to consider it in its former relation.

Magnesium is from the Latinized name for Magnesia, a city in Asia Minor. It is widely distributed, the principal minerals being *magnesite*, a carbonate; *dolomite*, a magnesium and calcium carbonate; *kieserite*, a sulphate; *carnallite*, a double magnesium and potassium chloride. It is also combined as a silicate in *talc*, *asbestos*, *meerschaum*, *serpentine*, etc. The metal is a silver-white color, losing its luster through the oxidation of its surface, and burning with a radiant light when heated to redness, magnesium oxide being formed.

Tests for Salts of Magnesium

Solutions of magnesium salts in the presence of ammonium chloride yield no precipitate with ammonium carbonate T.S., but on the subsequent addition of sodium phosphate T.S. a white precipitate is produced which is insoluble in ammonia T.S.

MAGNESII CARBONAS. U. S. Magnesium Carbonate

[Mag. Carb.]

Magnesium Carbonate is a mixture of hydrated magnesium carbonate and magnesium hydroxide, equivalent to not less than 39.2 per cent of MgO (40.32).

Preparation—It is largely prepared from *dolomite* ($MgCO_3.CaCO_3$) by first calcining it, suspending the calcined product in water saturated with CO_2, whereupon the magnesia, being soluble in carbonated water dissolves, forming the bicarbonate ($Mg(HCO_3)_2$). The lime is now separated, the magnesium solution evaporated, and the residue heated, liberating CO_2 and water and forming magnesium carbonate.

Magnesium carbonate varies in composition somewhat according to the process used. The reaction in making a carbonate corresponding to that of the U. S. P. would be explained as follows:

$$\underset{\text{magnesium sulphate}}{5MgSO_4} + \underset{\text{sodium carbonate}}{5Na_2CO_3} + \underset{\text{water}}{H_2O} = \underset{\text{magnesium carbonate}}{4MgCO_3.Mg(OH)_2} + \underset{\text{sodium sulphate}}{5Na_2SO_4} + \underset{\text{carbon cioxide}}{CO_2}$$

The process for making light magnesium carbonate differs from the heavy in the substitution of a larger proportion of cold water for the boiling water.

This furnishes a good illustration of the rule in precipitation, that dilute solutions produce light precipitates, and concentrated solutions heavy precipitates.

Description and Physical Properties—Light, white, friable masses, or a bulky, white powder. It is odorless, and is stable in the air.

Magnesium Carbonate is practically insoluble in water, to which, however, it imparts a slightly alkaline reaction. It is insoluble in alcohol, but is dissolved by dilute acids with effervescence.

When strongly heated, it loses water and carbon dioxide, and is converted into magnesium oxide.

Tests for Identity—When Magnesium Carbonate is treated with diluted hydrochloric acid, it dissolves with effervescence and the resulting solution responds to the reactions for magnesium, page 661.

Tests for Purity—Mix 1 Gm. of Magnesium Carbonate with 50 cc. of distilled water, heat the mixture to the boiling point, and cool. Then filter, and evaporate the filtrate to dryness on a water bath. The weight of the residue does not exceed 0.01 Gm. (*soluble salts*).

Dissolve 2.5 Gm. of Magnesium Carbonate in 50 cc. of diluted hydrochloric acid and 200 cc. of distilled water: the solution is colorless. Transfer 50 cc. of this solution to a 50 cc. graduated cylinder and add 0.2 cc. of potassium ferrocyanide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface is not greater than the color of a control solution prepared as follows: Dilute 0.2 cc. of ferric chloride T.S. with sufficient distilled water to make 1000 cc. Transfer 25 cc. of this solution to another 50 cc. graduated cylinder, and add 10 cc. of diluted hydrochloric acid and sufficient distilled water to make 50 cc. Then add 0.2 cc. of potassium ferrocyanide T.S. The two cylinders used in this test must be matched, be of practically colorless glass and have the same internal diameter (*iron*).

Dissolve 0.5 Gm. of Magnesium Carbonate in a slight excess of diluted hydrochloric acid (about 5 cc.), and dilute with distilled water to 25 cc.: a 10 cc. portion of this solution meets the requirements of the test for *heavy metals*, page 1519.

Dissolve 4 Gm. of Magnesium Carbonate in 50 cc. of diluted hydrochloric acid in a beaker of about 900 cc. capacity. Dilute this solution to about 400 cc. with distilled water, add 5 Gm. of ammonium chloride, heat to boiling, and add 50 cc. of ammonium oxalate T.S., followed by 5 drops of methyl orange T.S. and afterward by ammonia T.S. (previously diluted with two volumes of distilled water), added slowly in small portions, stirring constantly until the liquid has assumed a yellow color. This operation normally requires about twenty minutes. Allow the liquid to stand for four hours or overnight, collect the precipitate on a filter, wash it with hot, distilled water containing 1 per cent of ammonium oxalate solution, until the washings, after strongly acidifying with nitric acid, cease to react with silver nitrate T.S. Dissolve the precipitate by pouring 50 cc. of warm diluted hydrochloric acid in small portions over the filter, wash the filter with about 100 cc. of distilled water, collect the solution of the precipitate and washings in the same beaker, then dilute to 400 cc. with distilled water, and precipitate as before (omitting the addition of 5 Gm. of ammonium chloride). Allow the new precipitate to stand four hours or overnight, filter, and wash as before, then dry the precipitate within the filter paper and after cautious ignition in a platinum crucible heat the residue until of constant weight. The heat should be applied gently at first, the temperature should then be gradually increased, and finally the heat of a blast lamp should be applied for fifteen minutes or longer if necessary. Cool the crucible and contents in a desiccator before weighing. The weight of CaO so obtained does not exceed 0.032 Gm., corresponding to not more than 0.8 per cent (*limit of calcium oxide*).

Assay—Dissolve about 1 Gm. of Magnesium Carbonate, accurately weighed, in 30 cc. of normal sulphuric acid, and determine the residual acid by titrating with normal sodium hydroxide, using methyl orange T.S. as indicator. From the volume of the normal sulphuric acid consumed, deduct the volume of normal sulphuric acid corresponding to the per cent of calcium oxide found. The difference represents the normal sulphuric acid equivalent to the magnesium oxide present. Each cc. of normal sulphuric acid corresponds to 0.02016 Gm. of MgO or to 0.02804 Gm. of CaO.

This assay is explained on page 1457.

U. S. P. Preparations—Liquor Magnesii Citratis; Syrupus Tolu; Syrupus Zingiberis.

N. F. Preparations—Elixir Eriodictyi Aromaticum; Glyceritum Picis Pini; Liquor Aromaticus Alkalinus; Liquor Pancreatini; Liquor Phosphatum Acidus; Mistura Carminativa; Mistura Magnesiæ, Asafœtidæ et Opii; Syrupus Eriodictyi Aromaticus.

Uses—Magnesium carbonate is antacid, and in large doses cathartic. It is also employed externally as an absorbent or drying powder. The dose is from thirty to sixty grains (2 to 4 Gm.). It was at one time largely employed in making medicated waters to assist in diffusing the oils used in preparing them, but being slightly soluble it always imparts an alkaline reaction to the water, which is especially dangerous in dispensing, as aromatic waters made with it, will cause the gradual precipitation of free alkaloids like strychnine, atropine, etc., when the salt of the alkaloid is dissolved in such aromatic water. Its use in this manner is not recognized by the U. S. P.

MAGNESII OXIDUM. U. S. Magnesium Oxide

[Mag. Oxid.—Magnesia, Calcined Magnesia, Light Magnesia]

Magnesium Oxide contains, after ignition, not less than 96 per cent of MgO (40.32). Upon ignition it loses not more than 10 per cent.

Preparation—Magnesium carbonate is exposed in crucibles to a red heat, carbon dioxide and water are expelled, and magnesium oxide is left.

$$\underset{\text{magnesium carbonate}}{(MgCO_3)_4Mg(OH)_2} + \underset{\text{water}}{5H_2O} = \underset{\text{magnesium oxide}}{5MgO} + \underset{\text{carbon dioxide}}{4CO_2} + \underset{\text{water}}{6H_2O}$$

Magnesium Oxide is rendered less soluble if heated too strongly. It should always be kept in well-closed vessels; exposure to air and moisture causes the formation of carbonate and hydroxide.

Description and Physical Properties—A white, very bulky, odorless powder. On exposure to air it absorbs moisture and carbon dioxide.

Magnesium Oxide is practically insoluble in water and is insoluble in alcohol. It is dissolved by dilute acids.

Tests for Identity—A solution of Magnesium Oxide in diluted hydrochloric acid responds to the reactions for magnesium, page 661.

Tests for Purity—Boil 1 Gm. of Magnesium Oxide with 50 cc. of distilled water, cool and filter: the filtrate is not more than faintly alkaline to litmus paper, and when evaporated to dryness leaves not more than 0.02 Gm. of residue (*soluble salts*).

Boil a mixture of 0.1 Gm. of Magnesium Oxide with 5 cc. of distilled water, and after cooling pour it into 5 cc. of acetic acid: solution takes place without the evolution of more than a few isolated gas bubbles (*carbonate*).

It meets the requirements of the test for *iron* under *Magnesii Carbonas*, using 1 Gm. of Magnesium Oxide.

Dissolve 0.5 Gm. of Magnesium Oxide in a slight excess of diluted hydrochloric acid, and dilute with distilled water to 25 cc.: a 10 cc. portion of this solution meets the requirements of the test for *heavy metals*, page 1519.

Transfer to a porcelain crucible about 1 Gm. of Magnesium Oxide, weigh accurately, and expose to a low red heat (about 600° C.): it loses not more than 10 per cent of its weight (*water and other volatile substances*).

When determined by the method described under *Magnesii Carbonas*, using about 1.5 Gm. of freshly ignited Magnesium Oxide, accurately weighed, it shows not more than 2 per cent of calcium oxide.

Assay—Ignite about 0.5 Gm. of Magnesium Oxide to constant weight at a low red heat, weigh the residue accurately, dissolve it in 30 cc. of normal sulphuric acid, and determine the residual acid by titrating with normal sodium hydroxide, using methyl orange T.S. as indicator. From the volume of the normal sulphuric acid consumed, deduct the volume of normal sulphuric acid corresponding to the per cent of calcium oxide found. The difference represents the normal sulphuric acid equivalent to the magnesium oxide present. Each cc. of normal sulphuric acid corresponds to 0.02016 Gm. of MgO or to 0.02804 Gm. of CaO.

This assay is explained on page 1457.

Preserve in well-closed containers.

U. S. P. Preparations—Ferri Hydroxidum cum Magnesii Oxido; Pulvis Rhei Compositus. It is also used as a diluent and absorbent in extracts and to neutralize the resins in cascara sagrada.

N. F. Preparation—Massa Copaibæ.

Uses—Magnesium Oxide or *magnesia* is popularly used as a laxative and antacid, in doses of thirty grains (2 Gm.). In administering, the magnesia should be added to the diluent (water or milk), and not *vice versa*. If it fails to act when used as a laxative it should be followed by lemon juice or some other form of citric acid.

MAGNESII OXIDUM PONDEROSUM. U. S. Heavy Magnesium Oxide

[Mag. Oxid. Pond.—Heavy Magnesia]

Heavy Magnesium Oxide contains, after ignition, not less than 96 per cent of MgO (40.32). Upon ignition it loses not more than 10 per cent.

Heavy magnesium oxide is preferable to the ordinary magnesium oxide on account of its density. This often permits the decrease in bulk of the dose in

the ratio of nearly four to one. Magnesium oxide is rendered less bulky by trituration, and if the heavy carbonate is used for the calcination, a heavier powder is produced.

Description and Physical Properties—A white, dense, odorless and very fine powder, which meets the requirements of the tests for identity, purity, and the assay under *Magnesii Oxidum*. **Preserve** in well-closed containers.

N. F. Preparations—Fluidglyceratum Cascaræ Sagradæ Aromaticum; Pulvis Rhei et Magnesiæ Anisatus.

Uses—The uses and dose of heavy magnesia are the same as those of the light magnesia.

MAGMA MAGNESIÆ. U. S. Magnesia Magma

[**Magma Mag.**—Milk of Magnesia]

Magnesia Magma contains not less than 7 per cent of $Mg(OH)_2$ (58.34).

	Metric	Alternative
Magnesium Sulphate	**300 Gm.**	**10 oz. av.**
Sodium Hydroxide	**100 Gm.**	**3 oz. av. 148 gr.**
Distilled Water, a sufficient quantity,		
To make about	**1000 cc.**	**2 pints**

Dissolve the magnesium sulphate in sufficient distilled water to make 650 cc. [21 fl. oz.], place this in a vessel of about 5000 cc. [10 pints] capacity, and heat to boiling. Dissolve the sodium hydroxide in sufficient distilled water to make 1000 cc. [2 pints], add this slowly to the boiling solution of magnesium sulphate, and continue the boiling for thirty minutes. Transfer the mixture to a cylindrical container of not less than 5000 cc. [10 pints], capacity, and fill with hot distilled water. Allow to stand until separation has occurred, and remove the supernatant liquid. Wash repeatedly with hot distilled water until sulphates have practically been eliminated, as shown by testing the supernatant liquid with barium chloride T.S. Concentrate the mixture by evaporation until it contains not less than 7 per cent of magnesium hydroxide.

Note—One-half cc. of oil of peppermint, or a sufficient quantity of oil of anise or other suitable flavoring may be added if desired.

Distilled water is used in this preparation because the slightest trace of iron will cause discoloration. If the available water supply is free from iron, and otherwise suitable, or if it has been heated to boiling with powdered magnesium carbonate (5 Gm. [73 gr.] in each 1000 cc. [2 pints]), and then filtered, distilled water will not be necessary.

The official process does not direct the preparation of a definite volume. It is apparently the intention, as is the commercial custom, after thorough washing, to allow it to settle, then draw off the clear liquid, and market only the milky magma, no upper limit being fixed for the $Mg(OH)_2$ content.

This preparation is also made on a large scale by mixing freshly calcined magnesium oxide with distilled water in proper proportion and, after hydration, which is accompanied by heat, the product is ready for use. This process has not been adopted generally because of the difficulty of obtaining freshly calcined magnesium oxide. The Keasbey and Mattison Company offer such an article in tightly-sealed containers, but if it is exposed to the air, magnesium oxide soon loses the property of forming a gelatinous magnesium hydroxide when mixed with water.

If the cork stoppers are not protected by dipping them in melted paraffin the magma soon darkens, due to action on the tannin of the cork. The product should be protected against freezing, as this alters the colloidal gel, a more dense precipitate forming and a clear water stratum separating on top.

Description and Physical Properties—A viscous, opaque, white mixture, from which more or less water usually separates on standing; free from mustiness.

Tests for Identity—It is alkaline to litmus paper and to phenolphthalein T.S.

A solution of 2 cc. of diluted hydrochloric acid and 1 cc. of Magnesia Magma responds to the reactions for magnesium, page 661.

Tests for Purity—The addition of 2 cc. of diluted hydrochloric acid to 1 cc. of Magnesia Magma causes not more than a slight effervescence (*carbonate*), and the resulting solution is not more than slightly turbid.

Dilute 20 cc. of Magnesia Magma with distilled water to make 200 cc. and allow it to stand until the precipitate has settled. Remove 50 cc. of the clear liquid, and evaporate it to dryness on a water bath. The residue, when dried to constant weight at 150° C., does not exceed 0.005 Gm. To another 50 cc. portion of the supernatant liquid, add 1 drop of methyl orange T.S. and titrate with tenth-normal sulphuric acid: not more than 0.4 cc. is required to produce a red color (*soluble alkalies*).

Assay—Place about 5 Gm. of Magnesia Magma in a tared flask, stopper, and weigh accurately, add 25 cc. of normal sulphuric acid, and after solution is complete titrate the excess of acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.02917 Gm. of $Mg(OH)_2$.

Preserve in wide-mouthed bottles, tightly stoppered with corks which have been dipped in melted paraffin.

U. S. P. Preparation—Ferri Hydroxidum cum Magnesii Oxido.

Uses—It is used as an antacid and laxative and the addition of a flavor, as suggested above, renders it very acceptable when used as an antacid mouthwash, for which purpose it is frequently used under a dentist's orders. The usual dose as an antacid is one fluidrachm (4 cc.); as a laxative, four fluidrachms (15 cc.).

MAGNESII SULPHAS. U. S. Magnesium Sulphate

[**Mag. Sulph.**—Epsom Salt]

Magnesium Sulphate contains not less than 48.60 per cent and not more than 53.45 per cent of $MgSO_4$ (120.38), corresponding to not less than 99.5 per cent of the crystallized salt [$MgSO_4.7H_2O$ = 246.49].

Preparation—This well-known salt is prepared from a number of mineral substances, the mineral *kieserite*, of Stassfurt, yielding the largest supply. It can also be made by neutralizing sulphuric acid with magnesium oxide, hydroxide, or carbonate.

Magnesium sulphate was formerly made as a by-product in the manufacture of carbonated waters; the mineral *magnesite* being decomposed by sulphuric acid and the carbon dioxide passed into the water.

$$\underset{\text{magnesite}}{MgCO_3} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{H_2SO_4} = \underset{\substack{\text{magnesium}\\\text{sulphate}}}{MgSO_4} + \underset{\substack{\text{carbon}\\\text{dioxide}}}{CO_2} + \underset{\text{water}}{H_2O}$$

In England, Epsom salt is sometimes prepared from *dolomite*, the double carbonate of magnesium and calcium, by driving off the carbon dioxide by heat, converting the residue into hydroxides, and then treating these with hydrochloric acid in amount insufficient for complete neutralization. Calcium chloride is formed; this is dissolved out by washing with water, and the purified magnesium oxide is converted into sulphate by treating it with sulphuric acid.

Description and Physical Properties—Small, colorless, prismatic needles or rhombic prisms, without odor, and having a cooling, saline, and bitter taste.

One Gm. of Magnesium Sulphate is soluble in 1.3 cc. of water and in about 1.1 cc. of glycerin, at 25° C. One Gm. is soluble in about 0.2 cc. of boiling water. It is sparingly soluble in alcohol at 25° C.

When exposed to warm air, the salt loses some of its water of crystallization and is converted into a white powder. Further heating removes more water, and at a temperature somewhat above 200° C. it is rendered anhydrous.

Tests for Identity—An aqueous solution of the salt (1 in 20) responds to the reactions for magnesium, page 661, and for sulphates, page 581.

Tests for Purity—An aqueous solution of the salt (1 in 20) is neutral to litmus paper.

One Gm. of the salt shows no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid, page 1556.

An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page

An aqueous solution of the salt meets the requirements of the test for *arsenic*, page 1512.

Assay—Dissolve about 1 Gm. of Magnesium Sulphate, accurately weighed, in 100 cc. of distilled water, gradually add to the solution, with constant stirring, an excess of sodium phosphate T.S. (about 20 cc.), allow the mixture to stand for ten minutes, then add 30 cc. of ammonia T.S. and let stand for four hours. Collect the precipitate on a filter, wash it with dilute ammonia T.S. (1 volume of ammonia T.S. to 19 volumes of distilled water) until the washings are free from sulphate. Dry, and ignite to constant weight. The weight of magnesium pyrophosphate($Mg_2P_2O_7$) multiplied by 1.081, indicates its equivalent in $MgSO_4$. Each Gm. of Magnesium Sulphate corresponds to not less than 0.4495 Gm. and not more than 0.4944 Gm. of magnesium pyrophosphate ($Mg_2P_2O_7$).

This assay is explained on page 1480.

Preserve in well-closed containers.

U. S. P. Preparation—Magma Magnesiæ.

N. F. Preparations—Infusum Sennæ Compositum; Sal Kissingense Factitium; Sal Kissingense Factitium Effervescens; Sal Magnesii Sulphatis Effervescens; Sal Vichyanum Factitium; Sal Vichyanum Factitium Effervescens.

History—This salt, which at one time sold for a shilling an ounce, was first obtained from the celebrated spring at Epsom, the English Spa, hence the common name. In continental Europe it is frequently called "*Seidlitz Salt*", because it is the principal active constituent in the Seidlitz spring of Germany. In America it has been called *Crab Orchard Salt*, because it was obtained from the waters of a spring by that name in Kentucky.

Uses—Magnesium sulphate is a valuable hydragogue cathartic, in doses of from one-half to one ounce (15 to 30 Gm.); if dissolved in iced water, its nauseous taste is not so perceptible as when water of ordinary temperature is used; it may be still further disguised by the use of orange juice. Hot concentrated, aqueous solutions of magnesium sulphate (about 1 pound per pint of water) are extensively used in the treatment of deep-seated infections, cloths being saturated and applied while hot. The action is much like that of a poultice and has the advantage of being sterile.

LIQUOR MAGNESII CITRATIS. U. S. Solution of Magnesium Citrate
[Liq. Mag. Cit.]

Solution of Magnesium Citrate contains, in each 100 cc., magnesium citrate corresponding to not less than 1.5 Gm. of MgO.

	Metric	Alternative
Magnesium Carbonate	**15.0 Gm.**	232 gr.
Citric Acid	**35.0 Gm.**	1 oz. av. 103 gr.
Syrup	**60.0 cc.**	2 fl. oz.
Purified Talc	**5.0 Gm.**	77 gr.
Oil of Lemon	**0.1 cc.**	1.5 min.
Potassium Bicarbonate	**2.5 Gm.**	39 gr.
Distilled Water, a sufficient quantity,		
To make	**350 cc.**	12 fl. oz.

Dissolve the citric acid in 150 cc. [5¼ fl. oz.] of hot distilled water in a suitable dish, and, having added the magnesium carbonate, previously mixed with 100 cc. [3½ fl. oz.] of distilled water, stir until it is dissolved. Then add the syrup, heat the mixed liquids to the boiling point, immediately introduce the oil of lemon, previously triturated with the purified talc, and filter the mixture, while hot, into a strong bottle (previously rinsed with boiling water) of suitable

capacity. Add enough boiled distilled water to make the product measure 350 cc. [12 fl. oz.]. Stopper the bottle with purified cotton, allow to cool, drop in the potassium bicarbonate, and immediately stopper the bottle securely. Lastly, shake the solution occasionally until the potassium bicarbonate is dissolved. Keep the bottle on its side in a cool place, preferably in a refrigerator.

NOTE—In this process the 2.5 Gm. [39 gr.] of potassium bicarbonate may be replaced by 2.1 Gm. [32 gr.] of sodium bicarbonate, preferably in tablet form.

Description and Physical Properties—A slightly yellow, clear, effervescent liquid, having a sweet, acidulous taste and a lemon flavor.

Tests for Purity—Add 1 cc. of glacial acetic acid and 3 cc. of an aqueous solution of potassium acetate (1 in 2) to 10 cc. of Solution of Magnesium Citrate, shake the mixture vigorously, then gently rub the sides of the test tube with a glass rod for a few minutes, and allow to stand for one hour: no white crystalline precipitate soluble in ammonia T.S. is produced (*tartaric acid*).

Dilute 2 cc. of the Solution with 8 cc. of distilled water, and add 5 drops of hydrochloric acid and 1 cc. of barium chloride T.S.: no turbidity is produced within one minute (*sulphate*).

Dilute 2 cc. of the Solution with distilled water to 45 cc., add 5 cc. of ammonium oxalate T.S. and mix well: the resulting turbidity, if any, is not greater than the turbidity in a control test made with 1 cc. of a solution prepared as follows: Dissolve 1 Gm. of calcium carbonate, previously dried to constant weight at 200° C., in 1 cc. of acetic acid and 5 cc. of distilled water. Boil for about one minute, and dilute with distilled water to 100 cc. (*calcium*).

Boil down exactly 10 cc. of the Solution to about 5 cc. to expel carbon dioxide, dilute with 15 cc. of distilled water, and titrate with half-normal sodium hydroxide, using phenolphthalein T.S. as indicator: it requires not less than 9.5 cc. of the alkali for neutralization (*minimum of acidity*). Concentrate the liquid, and transfer it completely with the aid of a little distilled water to a platinum or porcelain crucible, evaporate to dryness, and proceed as directed under the assay for alkali salts of organic acids, page 1514: not less than 28 cc. of half-normal sulphuric acid should be consumed (*minimum of total citric acid*).

Assay for Magnesium Oxide—Measure exactly 10 cc. of Solution of Magnesium Citrate, transfer to a platinum or porcelain dish, evaporate to dryness, and ignite until most of the carbonaceous matter has burned off. Add to the residue 20 cc. of diluted hydrochloric acid, heat on a water bath for fifteen minutes, filter if necessary, and wash the residue thoroughly with hot distilled water. To the combined filtrate and washings, which should measure about 100 cc. add an excess of sodium phosphate T.S. (about 20 cc.), then gradually add ammonia T.S. with constant stirring until slightly alkaline. After ten minutes add 30 cc. of ammonia T.S. and allow the mixture to stand for twelve hours. Then filter, and wash the precipitate with a mixture of 1 volume of ammonia T.S. and 19 volumes of distilled water until free from chloride. Dry, and ignite to constant weight. The weight of the magnesium pyrophosphate ($Mg_2P_2O_7$) so obtained is not less than 0.414 Gm., indicating an equivalent of not less than 1.5 Gm. of MgO in 100 cc. of the Solution.

This assay is explained on page 1481.

A few modifications in the manipulation of the official process are advisable. The 15 Gm. of bulky magnesium carbonate may be replaced by 6.23 Gm. [98 gr.] of light calcined magnesia. The syrup should be introduced into the bottle, and the filtered solution of magnesium citrate very carefully poured in without stirring up the syrup. (For this purpose a hard rubber funnel, having the neck closed but with perforations on the side so that the liquid is delivered gently on the sides of the bottle, may be advantageously used.) The potassium bicarbonate, in large crystals (or in compressed blocks of the proper weight), is dropped into the bottle—it gradually dissolves in the syrup—and the bottle at once stoppered to prevent loss of carbonic acid gas. The bottle is not disturbed until it is called for, when a careful shake mixes the solution of the bicarbonate in the bottom of the bottle with the acid liquid above, liberating the carbonic acid gas, and the solution can then always be dispensed in a sparkling condition.

FIG. 427

Patent top citrate bottle

FIG. 428

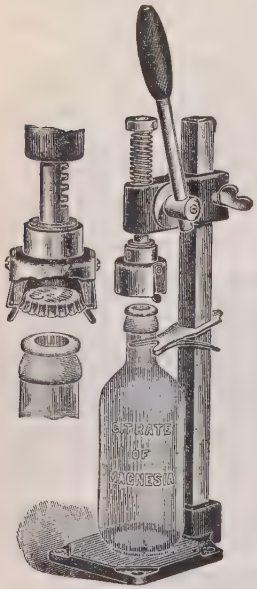
Metal cap citrate bottle

Fig. 427 and Fig. 428 show two types of "citrate bottles" now largely employed. The patent top of porcelain or glass which readily clamps in place

and which may be easily opened and closed without special tools is still the most popular style, although the metal cap, which is crimped into place by a special machine is also very popular. The chief objection to the latter is the difficulty in closing it tightly after it is once opened. The use of a metal cap requires a capping machine (see Fig. 429) costing about $5.00, but the bottles are much less expensive than those made with the "patent stopper", and the cap is easily removed and, unless it has been bent in its removal, it may even be sprung back on the bottle by pressing it against a flat surface, should the patient desire to use only a portion of its contents.

The Pharmacopœia has provided tests and an assay for this important solution and pharmacists should closely follow the official formula. For those who prepare relatively large quantities for their retail trade special facilities should be provided to expedite its manufacture. In Fig. 430 is illustrated an arrangement which is inexpensive but which lessens the amount of labor required.

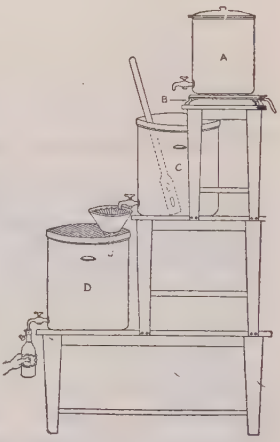
Fig. 429



Bottle capping machine

A tank for hot water, *A*, is mounted in an elevated position, on a gas-heated hot plate, *B*. The boiling water runs from this into the large earthenware crock, *C*, in which the solution is made and from this it can be run into the filter, the speed being adjusted to correspond with the rate of filtration. The tank for the filtered liquid should be fitted with a spigot, shaped to enter a "citrate bottle" to facilitate filling.

Fig. 430



Preparing solution of magnesium citrate

Great quantities of Solution of Magnesium Citrate are being manufactured in the larger centers by specialty houses; the solution is sterilized and delivered to retail customers each day, ready for sale. The official Solution contains more citric acid than is required for a normal "citrate", since the acid salt is more stable. This, however, makes the solution quite acid. If it is too acid for the patient, an additional amount of sugar or syrup will render it more palatable. The use of distilled water has been found necessary, as precipitation has frequently been traced to the use of ordinary water.

The U. S. P. process attempts by the use of heat to eliminate mold spores or other microörganisms which are likely to be present in the solution and cause confervoid growths. If the pharmacist experiences annoyance and loss from this cause, it may be overcome even more effectually by preparing the solution without any attempt at sterilization, then bottling, closing the bottles with absorbent cotton, and afterwards sterilizing them by heating in a closed vessel, containing boiling water. Any form of vessel which will hold the bottles, such as a wash boiler, may be used. The bottles should stand in water to the depth of about an inch, on a raised bottom made of wooden slats or tin and the lid of the vessel placed on loosely. The steam should heat the contents of the bottles to 100° C., and then the boiling be continued for at least thirty

minutes. The bottles may now be set aside closed only with the cotton stopper and may be kept for an extended period without danger of mold development. When a bottle is to be dispensed, the cotton is removed, the potassium bicarbonate added, and the permanent stopper at once inserted.

A white, crystalline, and odorless salt, containing not less than 98 per cent of *acid magnesium citrate*, is sold under the trade name *Citresia*. This is recognized in the 1925 N. N. R. It has a pleasant, acidulous taste, and the laxative and purgative action of solution of Magnesium Citrate, in doses of six drachms to one and one-half ounces (25 Gm. to 50 Gm.). It is manufactured by Horace North, Brooklyn, N. Y.

Uses—"*Citrate of magnesia*" or "*citrate*", as it is usually called, is one of the most agreeable saline cathartics available. It is usually given to adults in the quantity of the official formula, twelve fluidounces (350 cc.). The practice of dividing the dose, taking one-half three or four hours after the other, is often preferable.

MAGNESII CHLORIDUM. N. F. Magnesium Chloride

[**Magnes. Chlorid.**]

Magnesium Chloride contains, when dried for 24 hours over sulphuric acid, not less than 95 per cent of $MgCl_2.6H_2O$ (203.34).

Preparation—It is obtained from *carnallite*, a double potassium and magnesium chloride, by evaporating an aqueous solution to the proper concentration (45° Baumé) when magnesium chloride crystallizes, or by dissolving *magnesite*, magnesium carbonate, in hydrochloric acid. It is also a by-product in the preparation of potassium chloride from *carnallite*.

Magnesium chloride may be prepared by the action of hydrochloric acid on magnesium oxide, as follows:

$$\underset{\text{magnesium oxide}}{MgO} + \underset{\text{hydrochloric acid}}{2HCl} = \underset{\text{magnesium chloride}}{MgCl_2} + \underset{\text{water}}{H_2O}$$

The salt is then crystallized from solution.

Description and Physical Properties—Magnesium Chloride occurs as colorless, transparent crystals, or as white, translucent pieces; deliquescent in moist air.

One Gm. dissolves in about 0.6 cc. of water; it is readily soluble in alcohol. The aqueous solution of the salt (1 in 20) is neutral to litmus paper.

Tests for Identity—An aqueous solution of the salt, acidulated with nitric acid, yields a white precipitate upon the addition of silver nitrate T.S.

A mixture of 10 cc. of an aqueous solution of the salt (1 in 20) with 10 cc. of ammonium chloride T.S., rendered slightly alkaline with ammonia water, yields a white precipitate on the addition of sodium phosphate T.S.

Tests for Purity—One Gm. of the salt dissolves in 10 cc. of alcohol, leaving not more than .1 per cent of insoluble residue (*substances insoluble in alcohol*).

Add 1 cc. of potassium sulphate T.S. to 10 cc. of an aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid; no turbidity results (*barium*).

Ten cc. of an aqueous solution of the salt (1 in 200), acidulated with hydrochloric acid, is not reddened by potassium thiocyanate T.S. (*iron*).

Warm 5 cc. of an aqueous solution of the salt (1 in 10) with 10 cc. of sodium hydroxide T.S.; the odor of ammonia is not evolved.

A mixture of 10 cc. of an aqueous solution of the salt (1 in 20), 10 cc. of ammonium chloride T.S. and 5 cc. of ammonia water, is not rendered more than slightly turbid upon the addition of ammonium oxalate T.S. (*calcium*).

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

An aqueous solution of the salt meets the requirements of the test for arsenic (see page 1512).

Assay—Dissolve about 0.5 Gm. of Magnesium Chloride previously dried to constant weight over sulphuric acid and accurately weighed, in 50 cc. of distilled water in a 200 cc. measuring flask; add 3 cc. of nitric acid, then add 50 cc. of tenth-normal silver nitrate and sufficient distilled water to make the mixture measure 200 cc. Mix thoroughly, filter through a dry filter, reject the first 20 cc. of filtrate, then collect 100 cc. of filtrate, add 2 cc. of ferric ammonium sulphate T.S. and titrate the excess of silver nitrate with tenth-normal potassium thiocyanate.

Each cc. of tenth-normal silver nitrate used, corresponds to 0.010167 Gm. of $MgCl_2.6H_2O$. Each Gm. of Magnesium Chloride corresponds to not less than 93.4 cc. of tenth-normal silver nitrate.

This assay is explained on page 1463.

N. F. Preparation—Liquor Hydrastinæ Compositus.

Uses—It is used as a mild cathartic in doses of 4 drachms (16 Gm.).

SAL MAGNESII SULPHATIS EFFERVESCENS. N. F. Effervescent Magnesium Sulphate

[Sal. Mag. Sulph. Eff.]

	Metric	Alternative
Magnesium Sulphate, unefflouresced crystals	**500 Gm.**	2 oz. av.
Sodium Bicarbonate, dried and powdered	**403 Gm.**	1 oz. av. 267 gr.
Tartaric Acid, dried and powdered	**211 Gm.**	369 gr.
Citric Acid, unefflouresced crystals	**136 Gm.**	238 gr.
To make about	**1000 Gm.**	4 oz. av.

Dry the magnesium sulphate on a water bath, until it ceases to lose weight, then, after powdering the dry salt, mix it intimately with the citric acid, which has previously been powdered, add the tartaric acid, and thoroughly incorporate the sodium bicarbonate.

From this mixture prepare an effervescent salt as directed in the General Process (see page 475).

Average dose—240 grains (16 Gm.).

Unofficial Salts and Preparations of Magnesium

Magnesii Acetas, $Mg(C_2H_3O_2)_2+4H_2O$ Magnesium Acetate	Colorless, deliquescent crystals; very soluble in water. Like the citrate it is used as a cathartic. It should be kept well stoppered. Dose, 5 to 60 grains (0.3 to 3.8 Gm.)
Magnesii Iodidum, MgI_2+8H_2O Magnesium Iodide	A white, deliquescent, crystalline powder; soluble in water but decomposing in aqueous solution. It is used as an alterative and sialagogue. Dose, 2 to 10 grains (0.12 to 0.6 Gm.)
Magnesii Lactas, $Mg_2C_3H_5O_3+3H_2O$ Magnesium Lactate	A white, crystalline powder; it has a very bitter taste. It is soluble in water, and is used as a mild laxative. Dose, 15 to 45 grains (1 to 3 Gm.)
Magnesii Salicylas, $MgC_{14}H_{10}O_6+4H_2O$ Magnesium Salicylate	A white, crystalline powder; soluble in water. It is used as an antiseptic and antirheumatic. Dose, 8 to 30 grains (0.5 to 2 Gm.)
Magnesii Silicas, $H_2Mg_2Si_3O_9+H_2O$ Magnesium Silicate	Several forms of magnesium silicate occur in nature as the minerals *asbestos*, *meerschaum*, *talc* and *serpentine*. The pure compound is a fine, white powder; insoluble in water. It is used as an absorbent, astringent, and antiseptic. Dose, 60 to 240 grains (4 to 15 Gm.)
Liquor Magnesii Sulphatis Effervescens (N. F. IV) Effervescent Solution of Magnesium Sulphate	Each 350 cc. (12 fl. oz.) bottle is to contain 25 Gm. of magnesium sulphate, 4 Gm. of citric acid, 60 cc. of syrup of citric acid, in sufficient distilled water to make 350 cc. Just before stoppering the bottle, 2.5 Gm. of potassium bicarbonate are added. This solution is a laxative, similar in use to solution of magnesium citrate.
Magnesii Sulphis, $MgSO_3+6H_2O$ Magnesium Sulphite	A white, crystalline powder; soluble in water; gradually changing to sulphate on exposure to air. It is used as a cathartic and antiseptic. Dose, 10 to 60 grains (0.6 to 4 Gm.)
Magnesii Phenolsulphonas, $Mg(C_6H_5SO_4)+7H_2O$ Magnesium Phenolsulphonate	A white, crystalline powder; soluble in water. It is a laxative and intestinal antiseptic. Dose, 15 to 30 grains (1 to 2 Gm.)
Crab Orchard Salt	A mild, saline purgative, consisting mainly of magnesium sulphate and obtained by evaporating the waters of Crab Orchard Springs, Kentucky. Dose, from 1 to 2 teaspoonfuls.

Calcium, Ca; 40.07

Calcium is from the Latin word "calx" which is now applied to calcium oxide. Calcium is a very abundant element occurring in nature as carbonate (*limestone*), sulphate (*gypsum*), phosphate, silicate, chloride, fluoride, etc. It belongs to the class of metals. When heated, it burns with a bright light. It is of a light yellow color, and is ductile like gold; it may be hammered into very thin sheets but it is not permanent in the air. It forms but one chloride. The oxide, carbonate, sulphate, phosphate, and hypophosphite are of pharmaceutical interest.

The N. N. R. description, in part as follows, provides a concise picture of the value of calcium salts in body functions. "Calcium performs important functions, especially in the deposition of calcium salts in bone, in the regulation of nervous, muscular, and glandular activity, and in the coagulation of the blood.

"Rickets and osteomalacia show defective deposition of calcium in the bone, but this seems to be the result and not the cause of the disorder.

"The administration of calcium salts has been found useful against the skin rashes of serum disease, against other urticarias, against diarrhea, etc.

"Calcium depresses the nervous functions and is, therefore, more or less efficacious against convulsions. It cannot usually be introduced safely in effective quantities, but it has been asserted that it enhances markedly the sedative effects of bromides in resistant cases of epilepsy.

"For oral administration, calcium chloride is generally employed; for hypodermic use, the less irritant lactate is preferred."

Tests for Salts of Calcium

In neutral or alkaline solutions, or in solutions of calcium salts free from mineral acid, ammonium oxalate T. S. produces a white precipitate. This precipitate is insoluble in acetic acid, but dissolves in hydrochloric acid. Calcium salts moistened with hydrochloric acid impart a yellowish-red color to a non-luminous flame.

CALX. U. S. Lime

[Calcium Oxide—QUICKLIME]

Lime, when freshly ignited to constant weight with a blast lamp, contains not less than 95 per cent of CaO (56.07). It loses not more than 10 per cent of its weight on ignition.

Preparation—Lime, or calcium oxide, is a very important alkaline earth, and is made by calcining limestone, or native calcium carbonate, in kilns with strong heat; carbon dioxide is expelled.

$$\underset{\text{calcium carbonate}}{CaCO_3} = \underset{\text{lime}}{CaO} + \underset{\text{carbon dioxide}}{CO_2}$$

Description and Physical Properties—Hard, white or grayish-white masses or granules, or a white powder. It is odorless.

One Gm. of Lime is soluble in 840 cc. of water at 25° C. and in 1740 cc. of boiling water. It is soluble in glycerin and in syrup, but is insoluble in alcohol.

Tests for Identity—When moistened with water, Lime becomes heated, and is gradually converted into a white powder (calcium hydroxide or slaked lime). When this is mixed with about 3 or 4 times its weight of water, it forms a smooth magma (milk of lime).

Water, when agitated with Lime, becomes alkaline to litmus paper.

Slake 1 Gm. of Lime with 20 cc. of distilled water and add acetic acid until the lime is dissolved: the resulting solution responds to the reactions for calcium, page 671.

Tests for Purity—Slake 1 Gm. of Lime, thoroughly mix it with 50 cc. of water, and decant the greater portion of the milky liquid: the addition of an excess of diluted hydrochloric acid to the residue does not cause more than a slight effervescence (*carbonate*).

Slake 5 Gm. of Lime, then mix it with 100 cc. of distilled water, followed by hydrochloric acid, drop by drop, with agitation until solution takes place: the resulting solution after boiling and cooling should be acid and should not deposit more than 0.05 Gm. of insoluble matter.

Ignite a portion of Lime to constant weight in a tared platinum crucible, with a blast lamp: the loss in weight does not exceed 10 per cent (*volatile substances*).

Dissolve 0.5 Gm. of Lime in 10 cc. of diluted hydrochloric acid, neutralize with ammonia T.S., completely precipitate the calcium by adding ammonium oxalate T.S., and then filter: the filtrate, on evaporation and ignition leaves not more than 0.004 Gm. of fixed residue (*magnesium, other alkali earths, or alkalies*).

Assay—Ignite about 1 Gm. of Lime to constant weight over a blast lamp, weigh accurately, dissolve in 20 cc. of diluted hydrochloric acid, cool the solution, dilute with distilled water to 100 cc., and mix well. Transfer 20 cc. of this solution to a 200 cc. volumetric flask, and proceed with the assay as directed under *Calcii Carbonas Præcipitatus*. Each cc. of tenth-normal oxalic acid corresponds to 0.002804 Gm. of CaO.

This assay is explained on page 1473.

Preserve in air-tight containers, in a dry place.

U. S. P. Preparations—Fluidextractum Cascaræ Sagradæ Aromaticum; Liquor Calcii Hydroxidi; Sulphur Præcipitatum.

N. F. Preparations—Fluidglyceratum Cascaræ Sagradæ Aromaticum; Liquor Calcis Sulphuratæ.

Uses—Externally, lime acts as an escharotic; it enters into the composition of many depilatory powders. It is used as the starting point in making official lime water.

LIQUOR CALCII HYDROXIDI. U. S. Solution of Calcium Hydroxide

[Liq. Calc. Hydrox.—Liquor Calcis U. S. P. IX, Lime Water]

Solution of Calcium Hydroxide is an aqueous solution containing, in each 100 cc., not less than 0.14 Gm. of $Ca(OH)_2$ at 25° C. The strength in calcium hydroxide varies with the temperature at which the solution is stored, being about 0.17 Gm. per 100 cc. at 15° C. and diminishing as the temperature rises.

	Metric	Alternative
Lime	**25 Gm.**	365 gr.
Water, a sufficient quantity.		

Slake the lime by the addition of about 50 cc. [1½ fl. oz.] of warm water. Transfer the mixture to a bottle having a capacity of about 4000 cc. [8 pints], and add 950 cc. [30½ fl. oz.] of water. Agitate the mixture occasionally during half an hour, allow it to settle, and then decant and reject the clear liquid. To the residue add sufficient water to make about 4000 cc. [8 pints], agitate thoroughly, stopper the bottle and set it aside in a cool place. Decant and dispense the clear liquid.

The undissolved portion should not be used for making additional quantities of Solution of Calcium Hydroxide unless the solution so prepared is found to be of full strength when assayed.

Lime water is very extensively used in pharmacy; the object of keeping it upon undissolved lime is to insure a saturated solution. Lime is but sparingly soluble in water and less soluble in hot water than in cold; when the solution is heated, a deposition of lime takes place which is redissolved on cooling. A solution of lime containing particles of undissolved lime in suspension is termed *milk of lime.*

Description and Physical Properties—A clear, colorless, odorless liquid with an alkaline taste. Specific gravity: about 1.00 at 25° C.

Test for Identity—Solution of Calcium Hydroxide is strongly alkaline to litmus paper.

It absorbs carbon dioxide from the air, a film of calcium carbonate forming on the surface of the liquid.

On being heated it becomes turbid, due to the separation of calcium hydroxide which redissolves when the liquid is cooled.

Test for Purity—The alkaline reaction of the Solution entirely disappears after it has been saturated with carbon dioxide and subsequently boiled (*alkalies and their carbonates*).

Assay—Titrate exactly 50 cc. of Solution of Calcium Hydroxide at 25° C. with tenth-normal sulphuric acid, using phenolphthalein T.S. as indicator. Each cc. of tenth-normal sulphuric acid corresponds to not less than 0.003705 Gm. of $Ca(OH)_2$.

This assay is explained on page 1455.

Preserve in well-filled, tightly-stoppered bottles.

U. S. P. Preparation—Linimentum Calcis.

N. F. Preparations—Linimentum Calaminæ; Lotio Calaminæ; Lotio Flava; Lotio Nigra; Pasta Zinci Mollis.

When lime of official quality is obtained it has been suggested that it be slaked in larger quantity than that directed by the Pharmacopœia, the magma washed free from chloride and the moist magma or milk of lime then transferred to small bottles, completely filled and kept until needed for the making of lime water. This plan avoids the necessity of freshly slaking the

lime and washing the magma for each lot of lime water. Lime of official quality is now marketed in sealed glass tubes. Unless protected from the the air, lime soon becomes unfit for use, due to the action of carbon dioxide and partial hydration from moisture in the air. To avoid such deterioration the lime water may be stored in a large bottle from which it may be drawn by means of a glass siphon. A piece of rubber tubing is attached to the outlet of the siphon and is opened or closed by a pinchcock to be used when the lime water is drawn from the container. This siphon is held in place by a rubber stopper which also carries an air tube leading to a small bottle of solution of sodium hydroxide. By this plan all air admitted to the bottle of lime water is first passed through the NaOH solution and deprived of CO_2. The preparation of lime water involves a reaction expressed by the following equation:

$$\underset{\text{lime or calcium oxide}}{CaO} + \underset{\text{water}}{H_2O} + \underset{\text{calcium hydroxide}}{Ca(OH)_2}$$

When it is exposed to the air, which almost always contains CO_2, it is quickly converted into the insoluble carbonate as follows:

$$\underset{\text{calcium hydroxide}}{Ca(OH)_2} + \underset{\text{carbon dioxide}}{CO_2} = \underset{\text{calcium carbonate}}{CaCO_3} + \underset{\text{water}}{H_2O}$$

Uses—Probably the most extensive use of lime water in medicine is in checking nausea, although its value is greatly overestimated; it contains so small a proportion of alkali that it would require upwards of a tumblerful to have any real effect. It is usually administered with milk when used for correcting its acidity, especially in infant feeding. It is employed externally to allay inflammation, and in washes of various kinds. The dose of lime water is four fluidrachms (15 cc.).

CALX CHLORINATA. U. S. Chlorinated Lime

The activity of this compound is based upon the amount of available chlorine present, and it is therefore most appropriately considered under that head (see page 568).

CALCII BROMIDUM. U. S. Calcium Bromide
[Calc. Brom.]

Calcium Bromide is a hydrated salt, containing not less than 84 per cent of $CaBr_2$ (199.91).

Preparation—Calcium bromide may be made by the simple process of adding precipitated calcium carbonate, in excess, to hydrobromic acid, filtering, evaporating the solution to dryness, and granulating the product.

$$\underset{\text{calcium carbonate}}{CaCO_3} + \underset{\text{hydrobromic acid}}{2HBr} = \underset{\text{calcium bromide}}{CaBr_2} + \underset{\text{water}}{H_2O} + \underset{\text{carbon dioxide}}{CO_2}$$

It may also be made by adding milk of lime to a boiling solution of ammonium bromide until ammoniacal vapors cease to be evolved. The solution is then filtered and the salt granulated. Care should be used to protect the product from moisture.

$$\underset{\text{ammonium bromide}}{2NH_4Br} + \underset{\text{calcium hydroxide}}{Ca(OH)_2} = \underset{\text{calcium bromide}}{CaBr_2} + \underset{\text{ammonia}}{2NH_3} + \underset{\text{water}}{2H_2O}$$

Description and Physical Properties—A white, granular salt, having no odor. It is very deliquescent.

One Gm. of Calcium Bromide is soluble in 0.7 cc. of water and in 1.3 cc. of alcohol, at 25° C. One Gm. is soluble in 0.4 cc. of boiling water. It is insoluble in chloroform and in ether.

Tests for Identity—An aqueous solution of the salt (1 in 20) responds to the reactions for calcium, page 671, and for bromides, page 574.

Tests for Purity—An aqueous solution of Calcium Bromide (1 in 20) is neutral or slightly alkaline to litmus paper. Add a few drops of ferric chloride T.S. and 1 cc. of chloroform to 10 cc. of an aqueous solution of the salt (1 in 20), and shake the mixture: the chloroform does not acquire a violet tint (*iodide*).

Drop 1 cc. of diluted sulphuric acid upon about 1 Gm. of the powdered salt: no yellow color appears at once (*bromate*).

Dissolve 0.1 Gm. of the salt in 5 cc. of distilled water, add an excess of silver nitrate T.S. and a few drops of nitric acid, and filter. Wash the precipitate with distilled water, digest it for ten minutes with 5 cc. of ammonium carbonate T.S. and filter. Dilute the filtrate with enough distilled water to make 40 cc.: a 10 cc. portion of this dilution, acidulated with nitric acid and further diluted with enough water to make 50 cc. shows no more *chloride* than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid, page 1556.

A 20 cc. portion of an aqueous solution of Calcium Bromide (1 in 250) does not at once assume a blue color with potassium ferrocyanide T.S. (*iron*).

A 5 cc. portion of an aqueous solution of the salt (1 in 20), when acidulated with 1 drop of hydrochloric acid, shows no immediate turbidity with 1 cc. of barium chloride T.S. (*sulphate*).

Dissolve 1 Gm. of Calcium Bromide and 1 Gm. of sodium acetate in 5 cc. of distilled water, and render the solution slightly acid by the addition of a sufficient quantity (from 3 to 5 drops) of diluted acetic acid. After boiling and thoroughly cooling the solution, it does not become cloudy within five minutes after the addition, with agitation, of five drops of potassium dichromate T.S (*barium*).

Precipitate the calcium completely from 10 cc. of an aqueous solution of Calcium Bromide (1 in 20) by adding ammonium oxalate T.S., and filter: the filtrate on evaporation and ignition leaves not more than 0.004 Gm. of residue (*magnesium or alkalies*).

An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page 1519.

Assay—Proceed as directed under the assay for bromides, page 1515, using about 0.5 Gm. of Calcium Bromide, accurately weighed in a stoppered weighing bottle. Each cc. of tenth-normal silver nitrate corresponds to 0.009996 Gm. of $CaBr_2$.

This assay is explained on page 1462.

Preserve in well-closed containers.

N. F. Preparations—Elixir Bromidorum Quinque; Syrupus Bromidorum.

Uses—Calcium bromide is used as a nerve sedative in doses of fifteen to sixty grains (1 to 4 Gm.).

CALCII CARBONAS PRÆCIPITATUS. U. S. Precipitated Calcium Carbonate

[Calc. Carb. Præc.—Precipitated Chalk]

Precipitated Calcium Carbonate, when dried to constant weight at 200° C., contains not less than 98 per cent of $CaCO_3$ (100.08).

Preparation—This salt is readily prepared by double decomposition. The following process was formerly official in the British Pharmacopœia:

Take of calcium chloride 5 oz. av.; sodium carbonate 13 oz. av.; boiling distilled water a sufficiency. Dissolve the calcium chloride and the sodium carbonate each in 2 pints [Imperial measure] of the water; mix the two solutions; and allow the precipitate to subside. Collect this on a cloth strainer, wash it with boiling distilled water until the washings cease to give a precipitate with silver nitrate, and dry the product at the temperature of 100° C.

Calcium carbonate precipitates and sodium chloride remains in solution.

$$\underset{\text{calcium chloride}}{CaCl_2} + \underset{\text{sodium carbonate}}{Na_2CO_3} = \underset{\text{calcium carbonate}}{CaCO_3} + \underset{\text{sodium chloride}}{2NaCl}$$

The fineness of the powder is greatly promoted by using hot, dense solutions

Description and Physical Properties—A fine, white, microcrystalline powder, without odor or taste. It is stable in the air.

Precipitated Calcium Carbonate is practically insoluble in water. The solubility is increased by the presence of ammonium salts and also by carbon dioxide. Alkali hydroxides diminish its

solubility. It is insoluble in alcohol, and is dissolved with effervescence by diluted acetic, hydrochloric, or nitric acid.

When heated to about 825° C., the salt gradually loses carbon dioxide, and a residue of calcium oxide remains.

Tests for Identity—The addition of acetic acid to Precipitated Calcium Carbonate produces effervescence, and the resulting solution after boiling to expel carbon dioxide and neutralizing with ammonia T.S. responds to the reactions for calcium, page 671.

Tests for Purity—Mix 2 Gm. of Precipitated Calcium Carbonate with 100 cc. of distilled water and add hydrochloric acid, drop by drop, with agitation until solution takes place. This solution does not impart a green or crimson color to a non-luminous flame, and a 10 cc. portion of the liquid does not respond to the test for *heavy metals*, page 1519. Filter any insoluble residue remaining, wash with water until the washings show no more chloride, and ignite: the weight of the residue does not exceed 0.004 Gm.

Dissolve 0.5 Gm. of Precipitated Calcium Carbonate in 10 cc. of diluted hydrochloric acid, neutralize with ammonia T.S., completely precipitate the calcium by adding ammonium oxalate T.S., and then filter: the filtrate on evaporation and ignition leaves not more than 0.004 Gm. of residue (*magnesium or alkalies*).

Assay—Dry about 0.3 to 0.4 Gm. of Precipitated Calcium Carbonate to constant weight at 200° C., weigh accurately, dissolve it in 10 cc. of diluted hydrochloric acid and 10 cc. of distilled water, and boil the solution to expel all carbon dioxide. Transfer this solution to a 200 cc. volumetric flask, add 100 cc. of tenth-normal oxalic acid, render it alkaline with ammonia T.S., shake the mixture well, and allow it to stand for three hours at from 60° to 70° C. or overnight at room temperature. Cool the liquid if necessary, fill the flask with distilled water to 200 cc., mix well, filter through a dry filter into a dry flask, reject the first 20 cc. of the filtrate, and proceed as follows: Acidulate 100 cc. of the filtrate (corresponding to one-half of the Precipitated Calcium Carbonate taken) with diluted sulphuric acid, then add 25 cc. more of the diluted sulphuric acid, warm the solution to about 65° C. and titrate with tenth-normal potassium permanganate. Each cc. of tenth-normal oxalic acid corresponds to 0.005004 Gm. of $CaCO_3$.

This assay is explained on page 1473.

N. F. Preparations—Elixir Calcii Lactophosphatis; Liquor Alumini Subacetatis; Liquor Phosphatum Acidus; Liquor Phosphatum Compositus; Pasta Zinci Mollis; Syrupus Calcii Iodidi; Syrupus Calcii Lactophosphatis; Unguentum Sulphuris Compositum.

Uses—This form of calcium carbonate, known popularly as *precipitated chalk*, is largely used in tooth powders and similar preparations; it must be very finely powdered or the crystalline particles would cause erosion upon the enamel of the teeth. It is less useful than prepared chalk as an ingredient in chalk mixtures for internal use, because it does not possess the adhesive properties of the latter. The dose is fifteen grains (1 Gm.).

CRETA PRÆPARATA. U. S. Prepared Chalk

[Cret. Præp.—Drop Chalk]

Prepared Chalk is a native form of calcium carbonate freed from most of its impurities by elutriation, and containing, when dried to constant weight at 200° C., not less than 97 per cent of $CaCO_3$ (100.08).

Preparation—A process formerly official is as follows:

Take of chalk a *convenient quantity*. Add a little water to the chalk, and rub it into fine powder. Place this into a large vessel nearly full of water, stir briskly, and, after a short interval, decant the supernatant liquid, while yet turbid, into another vessel. Treat the coarser particles of the chalk, remaining in the first vessel, in a similar manner, and add the turbid liquid to that previously decanted. Lastly set the liquid aside, that the powder may subside, and, having poured off the water, dry the powder.

The object of this process is to effect the separation of the gritty particles in ordinary chalk by elutriation (see page 154). It is usual to form the moist magma into cones by trochiscation (see page 155). While elutriation effects the purification of the chalk to a certain extent, it does not separate the insoluble fine particles, and hence prepared chalk is chemically not so pure as precipitated calcium carbonate.

It also differs greatly in appearance from precipitated chalk, even after it has been reduced to a fine powder. It is usually not so white as the latter, and

it adheres to the fingers when handled. This adhesiveness fits it for many purposes. *Whiting*, a less pure form of prepared chalk obtained as a by-product in the elutriation process, is used for polishing.

Description and Physical Properties—A white to grayish-white, very fine, amorphous powder, often formed into "conical drops". It is odorless and tasteless, and is stable in the air.

Tests for Identity—When heated to about 825° C., Prepared Chalk gradually loses carbon dioxide and is converted into calcium oxide.

Dissolve about 0.1 Gm. of Prepared Chalk in 5 cc. of diluted acetic acid, and filter the solution: this solution responds to the reactions for calcium, page 671.

Tests for Purity—Prepared Chalk is practically insoluble in water and is insoluble in alcohol. It is decomposed and dissolved by diluted acetic, hydrochloric, or nitric acid, with copious effervescence. When a weighed amount of Prepared Chalk is dissolved in diluted hydrochloric acid and the insoluble residue collected and ignited, it yields not more than 2 per cent of the amount of Prepared Chalk taken.

Assay—Proceed as directed under *Calcii Carbonas Præcipitatus*.

This assay is explained on page 1473.

U. S. P. Preparations—Hydrargyrum cum Creta; Mistura Cretæ; Pulvis Cretæ Compositus.

N. F. Preparations—Dentifricium; Pulvis Cretæ Aromaticus.

Uses—This is the form of chalk which is used in medicine almost exclusively as it occurs in amorphous particles which have a greater adhesive property than precipitated calcium carbonate, which is crystalline. It is antacid, and is admirably adapted for the treatment of diarrhea. Dose, fifteen grains (1 Gm.).

CALCII CHLORIDUM. U. S. Calcium Chloride
[Calc. Chlor.]

Calcium Chloride is a hydrated salt containing not less than 75 per cent of $CaCl_2$ (110.99).

Preparation—Hydrated calcium chloride is obtained as a by-product of various industrial processes, such as the manufacture of ammonia water and ammonia soda, but may be prepared by saturating hydrochloric acid with chalk or marble, and carefully evaporating to dryness, at a temperature not exceeding 200° C., until it contains about 24 per cent of water.

$$\underset{\text{calcium carbonate}}{CaCO_3} + \underset{\text{hydrochloric acid}}{2HCl} = \underset{\text{calcium chloride}}{CaCl_2} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—White, slightly translucent, hard, odorless fragments or granules. It is very deliquescent.

One Gm. of Calcium Chloride is soluble in 1.2 cc. of water, and in about 10 cc. of alcohol, at 25° C. One Gm. is soluble in 0.7 cc. of boiling water and in about 2 cc. of boiling alcohol.

Tests for Identity—An aqueous solution of the salt (1 in 10) responds to the reactions for calcium, page 671, and for chlorides, page 567.

Tests for Purity—An aqueous solution of Calcium Chloride (1 in 20) is neutral or slightly alkaline to litmus paper.

Add ammonia water to an aqueous solution of the salt (1 in 20) until alkaline: no turbidity or precipitation occurs either before or after boiling (*iron, aluminum, or phosphates*).

Precipitate the calcium completely from 10 cc. of an aqueous solution of the salt (1 in 20) by adding ammonium oxalate T.S. and filter: the filtrate on evaporation and ignition leaves not more than 0.004 Gm. of residue (*magnesium or alkalies*).

An aqueous solution of the salt does not respond to the test for *heavy metals*, page 1519.

Assay—Proceed as directed under the assay for chlorides, page 1514, using about 0.3 Gm. of Calcium Chloride, accurately weighed in a stoppered weighing-bottle. Each cc. of tenth-normal silver nitrate corresponds to 0.00555 Gm. of $CaCl_2$.

This assay is explained on page 1463.

Preserve in well-stoppered bottles.

N. F. Preparation—Liquor Hydrastinæ Compositus.

Uses—It is used in internal hemorrhages, in certain bone diseases, nervous disorders, tuberculosis, enteritis, and wherever there is a deficiency of lime in the system. The dose is from five to fifteen grains (0.3 to 1 Gm.). It is incompatible with carbonates, phosphates, tartrates, and sulphates, since it forms

with these, insoluble calcium salts. Fused calcium chloride is used in chemical processes for dehydrating gases; this it does through its powerful affinity for water. It is also used as a dehydrating agent in desiccators.

CALCII GLYCEROPHOSPHAS. U. S. Calcium Glycerophosphate

[Calc. Glycerophos.—Calcium Glycerinophosphate]

The normal calcium salt of glycerophosphoric acid [$C_3H_5(OH)_2PO_4H_2 = 172.13$] containing, when dried to constant weight at 130° C., not less than 98 per cent of $C_3H_5(OH)_2PO_4Ca$ (210.18).

Preparation—This salt is prepared by adding glycerophosphoric acid to an excess of milk of lime or calcium carbonate, filtering out the excess of calcium salt, removing any dissolved lime by the addition of carbon dioxide, concentrating in vacuum, and precipitating the glycerophosphate by the addition of alcohol.

The following equation illustrates the reaction that takes place:

$$\underset{\text{glycerophosphoric acid}}{C_3H_5(OH)_2PO_4.H_2} + \underset{\text{calcium hydroxide}}{Ca(OH)_2} = \underset{\text{calcium glycerophosphate}}{C_3H_5(OH)_2PO_4Ca} + \underset{\text{water}}{2H_2O}$$

Description and Physical Properties—A fine, white, odorless powder. It is somewhat hygroscopic.

One Gm. of Calcium Glycerophosphate is soluble in about 50 cc. of water at 25° C. It is more soluble in water at a lower temperature; citric acid increases its solubility in water. It is insoluble in alcohol.

Tests for Identity—A saturated aqueous solution of Calcium Glycerophosphate is alkaline to litmus paper and to phenolphthalein T.S.

A cold, saturated aqueous solution of the salt upon boiling yields white, iridescent scales of anhydrous calcium glycerophosphate. When heated above 170° C., the salt is decomposed, evolving inflammable vapors, and at a red heat is converted into calcium pyrophosphate.

A saturated aqueous solution of the salt responds to the reactions for calcium, page 671, and for glycerophosphates, page 678.

With lead acetate T.S. a saturated aqueous solution of the salt yields a white curdy precipitate, which is soluble in nitric acid.

Tests for Purity—Dissolve 1 Gm. of Calcium Glycerophosphate in 10 cc. of diluted nitric acid, and add an equal volume of cold ammonium molybdate T.S.: no precipitate is formed within one hour (*phosphates*).

An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page 1519.

One Gm. of Calcium Glycerophosphate shows no more *chloride* than 1 cc. of fiftieth-normal hydrochloric acid, page 1556.

Two-tenths of 1 Gm. of Calcium Glycerophosphate shows no more *sulphate* than 1 cc. of fiftieth-normal sulphuric acid, page 1520.

Shake 1 Gm. of finely powdered Calcium Glycerophosphate with 25 cc. of dehydrated alcohol, filter the mixture, evaporate the filtrate on a water bath, and dry the residue for an hour at a temperature not exceeding 70° C.: the resulting residue weighs not more than 0.01 Gm. (*alcohol-soluble substances*).

The loss on drying a portion of the finely powdered salt to constant weight at 130° C. does not exceed 10 per cent (*water*).

Dry about 3 Gm. of Calcium Glycerophosphate to constant weight at about 130° C., weigh accurately, dissolve it in 250 cc. of distilled water, and then titrate with half-normal hydrochloric acid, using methyl orange T.S. as indicator, to a slight yet distinct pink. Each Gm. of dry Calcium Glycerophosphate requires not less than 9 cc. of half-normal hydrochloric acid (*minimum limit for glycerophosphate*).

Assay—Dry about 0.4 Gm. of Calcium Glycerophosphate to constant weight at 130° C., weigh accurately, dissolve in 20 cc. of a 5 per cent solution of acetic acid, and add 30 cc. of distilled water. Heat the mixture to boiling, and add an excess of ammonium oxalate T.S. Collect the resulting precipitate, wash, dry, and ignite to constant weight. This residue of calcium oxide corresponds to not less than 26.1 per cent of the weight of dried Calcium Glycerophosphate taken.

Dry a portion of Calcium Glycerophosphate to constant weight at 230° C. and ignite it to constant weight. The weight of calcium pyrophosphate corresponds to not less than 59.2 per cent of the weight of Calcium Glycerophosphate taken.

This assay is explained on page 1478.

Preserve in well-closed containers.

N. F. Preparations—Elixir Calcii et Sodii Glycerophosphatum; Elixir Glycerophosphatum Compositum; Elixir Terpini Hydratis et Creosoti Compositum.

Uses—It is used in doses of four to ten grains (0.25 to 0.6 Gm.) as a tonic and nervine, and where calcium salts are indicated.

Tests for Glycerophosphates

Glycerophosphates—Solutions of glycerophosphates yield no precipitate in the cold with ammonium molybdate T.S., but upon heating, an abundant yellow precipitate is formed. Moderately diluted solutions of glycerophosphates, when treated with calcium chloride T.S., remain unaffected in the cold but on boiling, a precipitate is produced which redissolves on cooling.

CALCII LACTAS. U. S. Calcium Lactate

[Calc. Lact.]

Calcium Lactate contains not less than 70 per cent and not more than 75 per cent of $Ca(C_3H_5O_3)_2$ (218.18), corresponding to not less than 98 per cent of the hydrated salt $[Ca(C_3H_5O_3)_2.5H_2O = 308.26]$.

Preparation—It may be prepared by dissolving calcium carbonate in warm diluted lactic acid, filtering while hot, and crystallizing.

$$\underset{\text{calcium carbonate}}{CaCO_3} + \underset{\text{lactic acid}}{2HC_3H_5O_3} = \underset{\text{calcium lactate}}{Ca(C_3H_5O_3)_2} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{water}}{H_2O}$$

In the manufacture of lactic acid calcium lactate is obtained as an intermediate product.

Description and Physical Properties—White, granular masses or powder. It is odorless or has a slight odor. It is somewhat efflorescent and at 120° C. becomes anhydrous.

One Gm. of Calcium Lactate is soluble in 20 cc. of water at 25° C. It is practically insoluble in alcohol.

Tests for Identity—An aqueous solution of the salt (1 in 20) responds to the reactions for calcium, page 671, and for lactates, page 1183.

Tests for Purity—When dried to constant weight at 120° C., Calcium Lactate loses not less than 25 per cent and not more than 30 per cent of its weight.

A solution of 1 Gm. of Calcium Lactate in 20 cc. of distilled water requires not more than 0.5 cc. of tenth-normal sodium hydroxide for neutralization, using phenolphthalein T.S. as indicator.

An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page 1519.

Add ammonium oxalate T.S. to 20 cc. of a hot aqueous solution of Calcium Lactate (1 in 20) until no further precipitate is produced, filter the mixture after three hours, and wash the precipitate with 50 cc. of distilled water: the combined filtrate and washings leave not more than 0.01 Gm. of residue on evaporation and subsequent ignition (*magnesium or alkalies*).

Stir about 0.5 Gm. of the salt with 1 cc. of sulphuric acid: the mixture does not emit an odor of volatile fatty acids even on warming.

Assay—Dry about 2 Gm. of Calcium Lactate to constant weight at 120° C., weigh accurately in a crucible, incinerate, wash the incinerated residue into a flask with about 50 cc. of distilled water, add exactly 50 cc. of half-normal hydrochloric acid, and titrate the excess of acid with half-normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of half-normal hydrochloric acid corresponds to 0.05455 Gm. of $Ca(C_3H_5O_3)_2$.

This assay is explained on page 1459.

Preserve in well-closed containers.

Uses—It is used to control hemorrhage, and in other diseases where calcium is indicated. Dose, from five to ten grains (0.3 to 0.6 Gm.) three or four times a day.

CALCII HYPOPHOSPHIS. N. F. Calcium Hypophosphite

(U. S. P. IX)

[Calc. Hypophos.]

Calcium Hypophosphite contains, when dried to constant weight over sulphuric acid, not less than 98 per cent of $Ca(PH_2O_2)_2$ (170.18).

Caution should be observed in dispensing Calcium Hypophosphite as an explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents.

Preparation—This salt is made by boiling milk of lime and phosphorus together until the spontaneously inflammable gas, hydrogen phosphide, ceases to be evolved; it is necessary to provide for the safe escape of this gas by conducting it by a hood into a powerful draught.

$$\underset{\text{phosphorus}}{8P} + \underset{\text{calcium hydroxide}}{3Ca(OH)_2} + \underset{\text{water}}{6H_2O} = \underset{\text{calcium hypophosphite}}{3Ca(PH_2O_2)_2} + \underset{\text{hydrogen phosphide}}{2PH_3}$$

The liquid is filtered to separate the insoluble phosphate and residuary lime, then concentrated, and refiltered to separate the calcium carbonate formed by the action of the air on a little lime held in solution, and lastly evaporated till a pellicle appears; after which the salt may be allowed to crystallize by setting the liquid aside, or may be obtained in the granular form by continuing the heat, and stirring.

The heat employed in evaporating the solution should not be above 85° C. (185° F.), for fear of explosions, several accidents having occurred through carelessness in this respect, even when the evaporation was conducted with a water bath.

Description and Physical Properties—Calcium Hypophosphite occurs as colorless, transparent, monoclinic prisms, as small lustrous scales, or as a white, crystalline powder; odorless; having a nauseous and bitter taste, permanent in the air.

One Gm. of Calcium Hypophosphite is slowly soluble in 6.5 cc. of water at 25° C.; insoluble in alcohol.

Tests for Identity—When heated the salt decrepitates and begins to decompose, giving off water and evolving spontaneously inflammable hydrogen phosphide, and on complete ignition leaving a residue of calcium pyrophosphate.

When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, with agitation, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. Upon the further addition of the solution of Calcium Hypophosphite the precipitate becomes gray from reduction to metallic mercury.

An aqueous solution of Calcium Hypophosphite (1 in 20) yields with ammonium oxalate T.S. a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid.

Tests for Purity—Dissolve 1 Gm. of the salt in 20 cc. of distilled water; it requires not more than 1 cc. of tenth-normal potassium hydroxide to produce a pink color, phenolphthalein T.S. being used as indicator.

When 1 Gm. of the salt is dissolved in 20 cc. of distilled water, not more than 0.005 Gm. of residue remains (*phosphate*).

Mix 5 cc. of an aqueous solution of the salt (1 in 10) in a test tube with 0.5 cc. of diluted hydrochloric acid and heat on a water bath; no offensive odor develops within thirty minutes.

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

Pour 5 cc. of an aqueous solution of the salt (1 in 25) into a beaker containing 3 cc. of nitric acid, diluted with about 10 cc. of distilled water, and evaporate it to dryness on a water bath. The residue meets the requirements of the test for arsenic (see page 1512).

Assay—Dissolve about 0.75 Gm. of Calcium Hypophosphite, previously dried to constant weight over sulphuric acid and accurately weighed, in 10 cc. of distilled water, add 10 cc. of nitric acid and evaporate to dryness on a water bath. Add 5 cc. of nitric acid to the residue, again evaporate to dryness on a water bath and dissolve the residue in sufficient distilled water to measure 100 cc. Transfer 10 cc. of this solution to a 100 cc. graduated flask, add sodium hydroxide T.S. (free from chloride) until a slight, permanent precipitate is produced; then add 50 cc. of tenth-normal silver nitrate and agitate well. Then gradually add zinc oxide (free from chloride) in small portions until the liquid is neutral to litmus. Then add distilled water to make 100 cc., agitate the mixture thoroughly, filter through a dry filter, rejecting the first 20 cc. of filtrate, collect 50 cc. of the subsequent filtrate, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate to the production of a red color.

Each cc. of tenth-normal silver nitrate corresponds to 0.002836 Gm. of $Ca(PH_2O_2)_2$. Each Gm. of Calcium Hypophosphite, dried to constant weight, corresponds to not less than 345.5 cc. of tenth-normal silver nitrate.

This assay is explained on page 1464.

Preserve it in well-closed containers. Caution should be observed in dispensing Calcium Hypophosphite as an explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents.

N. F. Preparations—Emulsum Olei Morrhuæ cum Hypophosphitibus; Liquor Hypophosphitum Compositus; Syrupus Calcii et Sodii Hypophosphitum; Syrupus Calcii Hypophosphitis; Syrupus Hypophosphitum; Syrupus Hypophosphitum Compositus.

Uses—Calcium hypophosphite is used pharmaceutically to prepare the other hypophosphites, hypophosphorous acid, and as an ingredient in the syrup and compound syrup of hypophosphites and other preparations. Medicinally, it is used in phthisis and other wasting diseases, and in cases of defective nerve nutrition. The dose is from five to thirty grains (0.32 to 2 Gm.).

CALCII LACTOPHOSPHAS. N. F. Calcium Lactophosphate

[Calc. Lactophos.]

A mixture in variable proportions of calcium lactate, calcium acid lactate, and calcium acid phosphate, corresponding to not less than 1.5 per cent and not more than 2 per cent of (P_2O_5).

Preparation—It may be prepared by mixing 15 parts of calcium carbonate, 30 parts of lactic acid, 9.86 parts of phosphoric acid and 150 parts of distilled water, and evaporating to dryness in a warm place, avoiding the use of a water bath.

Description and Physical Properties—Calcium Lactophosphate occurs in white granules or as a white powder, without odor.

It is soluble in water, almost insoluble in alcohol.

Its aqueous solution (1 in 20) is acid to litmus.

Tests for Identity—The addition of ammonium oxalate T.S. to an aqueous solution of Calcium Lactophosphate produces a white precipitate insoluble in acetic acid but soluble in hydrochloric acid.

Add 10 cc. of diluted sulphuric acid and 5 cc. of potassium permanganate T.S. to 5 cc. of an aqueous solution of Calcium Lactophosphate (1 in 20) and gently warm the mixture; the odor of acetaldehyde is evolved.

Add silver nitrate T.S. or ammonium molybdate T.S. to separate portions of an aqueous solution of Calcium Lactophosphate (1 in 20); a yellow precipitate is produced.

Tests for Purity—Mix 0.5 Gm. of Calcium Lactophosphate with 5 cc. of sulphuric acid; not more than a slight coloration results within one minute (*readily carbonizable impurities*).

Ten cc. of an aqueous solution of Calcium Lactophosphate (1 in 100) mixed with 1 cc. of diluted hydrochloric acid, does not at once become turbid on the addition of a few drops of barium chloride T.S. (*sulphate*).

Ten cc. of an aqueous solution of Calcium Lactophosphate (1 in 100) when mixed with a few drops of nitric acid, yields not more than an opalescence on the addition of a few drops of silver nitrate T.S. (*chloride*).

An aqueous solution of Calcium Lactophosphate does not respond to the test for heavy metals (see page 1519).

Mix 0.2 Gm. of Calcium Lactophosphate with 1 Gm. of potassium nitrate, ignite the mixture cautiously, in small portions at a time until the carbonaceous matter is all or nearly all burned off, then add to the residue 20 cc. of diluted sulphuric acid and evaporate the mixture until fumes of sulphuric anhydride are evolved. The residue meets the requirements of the test for arsenic (see page 1512).

Dissolve 1 Gm. of Calcium Lactophosphate and 2 Gm. of ammonium chloride in 75 cc. of distilled water, heat the solution to boiling and add an excess of ammonium oxalate T.S. (about 20 cc.). Allow the precipitate to subside completely, then filter and supersaturate the filtrate with ammonia water; not more than a slight turbidity is produced (*magnesium*).

Assay—Dissolve about 1 Gm. of Calcium Lactophosphate, accurately weighed, in a mixture of 15 cc. of distilled water and 10 cc. of nitric acid contained in a 200 cc. beaker, and then add ammonia T.S. to a point just short of neutralization. Dilute the solution to 100 cc., heat to 60° C., add 25 cc. of ammonium molybdate T.S. and agitate well. Allow the mixture to remain at 60° for fifteen minutes, then filter through paper and wash with distilled water until the washings are neutral. Transfer the precipitate and filter back to the beaker, dissolve the precipitate in 30 cc. of half-normal sodium hydroxide, and titrate the excess of alkali with half-normal hydrochloric acid, using phenolphthalein T.S. as indicator. Each cc. of half-normal alkali corresponds to 0.001544 Gm. of P_2O_5.

This assay is explained on page 1455.

N. F. Preparations—Lactophosphatis; Syrupus Calcii Lactophosphatis; Syrupus Calcii Lactophosphatis et Ferri.

Uses—It is used as a tonic and to supply calcium to the system, usually in the form of the official syrup. The dose is five to ten grains (0.32 to 0.65 Gm.).

CALCII PHOSPHAS PRÆCIPITATUS. N. F. Precipitated Calcium Phosphate

[Calc. Phos. Præc.]

Calcium Phosphate ($Ca_3(PO_4)_2$=310.29) losing, when dried at 200° C., not more than 4 per cent of moisture.

Preparation—Take of bone, calcined to whiteness, and in fine powder, 4 oz. troy; hydrochloric acid, 8 oz. troy; ammonia water, 12 fl. oz., or a sufficient quantity; distilled water, a sufficient quantity. Macerate the bone in the acid, diluted with a pint of distilled water, until it is dissolved, and filter the solution. Add another pint of distilled water, and then, gradually, ammonia water, until the liquid acquires an alkaline reaction. Mix the precipitate obtained, while yet in the state of magma, with twice its bulk of boiling distilled water, and pour the whole upon a strainer. Wash the precipitate with boiling distilled water until the washings cease to be affected by a solution of nitrate of silver, acidulated with nitric acid. Lastly dry the precipitate with a gentle heat.

Calcium phosphate exists in calcined bone; it is soluble in hydrochloric acid, but is precipitated from its solution by ammonia water, ammonium chloride remaining in solution.

It may be prepared from calcium chloride and sodium phosphate in the presence of ammonia water at boiling temperature. The reaction is as follows:

$$3CaCl_2 + 2Na_2HPO_4 + 2NH_4OH = Ca_3(PO_4)_2 + 4NaCl + 2NH_4Cl + 2H_2O$$

calcium chloride	sodium phosphate	ammonia water	calcium phosphate	sodium chloride	ammonium chloride	water

Description and Physical Properties—Precipitated Calcium Phosphate occurs as a white, amorphous or microcrystalline, bulky powder, odorless and tasteless; permanent in the air. At an intense white heat the salt fuses without decomposition.

Almost insoluble in cold water; partly decomposed by boiling water; almost insoluble in acetic acid, except when freshly precipitated; easily dissolved by hydrochloric or nitric acid; insoluble in alcohol.

Tests for Identity—When moistened with silver nitrate T.S., either before or after ignition, the salt acquires a yellow color (distinction from *acid calcium phosphate* which, after ignition when moistened with silver nitrate T.S., remains white).

For applying tests of identity and of purity, prepare a solution by shaking 2 Gm. of Precipitated Calcium Phosphate with 20 cc. of distilled water adding nitric acid, drop by drop, until solution is effected, and then sufficient distilled water to make the liquid measure 40 cc. While making this solution, no effervescence occurs on adding the acid (*carbonate*).

To a portion of this solution add a slight excess of ammonia water, then an excess of silver nitrate T.S. and afterwards acetic acid, drop by drop, until the excess of ammonia is neutralized; the color of the precipitate changes from white to yellow.

Ammonium molybdate T.S. precipitates from the solution yellow ammonium phosphomolybdate; the reaction is accelerated by a gentle heat, not exceeding 65° C.

Tests for Purity—Add to 5 cc. of the solution, acidulated with nitric acid, 0.5 cc. of silver nitrate T.S.; not more than a slight turbidity is produced (*chloride*).

Add to five cc. of the solution, strongly acidulated with nitric acid, 1 cc. of potassium sulphate T.S.; no turbidity appears within fifteen minutes (*barium*).

An aqueous solution of Precipitated Calcium Phosphate (1 in 50), obtained by shaking the salt with distilled water, adding hydrochloric acid, drop by drop, and heating until solution is effected, does not respond to the test for heavy metals (see page 1519).

Five cc. of a solution of Precipitated Calcium Phosphate in diluted nitric acid (1 in 25), heated with 1 cc. of sulphuric acid until fumes of sulphur trioxide appear, meets the requirements of the test for arsenic (see page 1512).

Preparations—Liquor Phosphatum Acidus; Liquor Phosphatum Compositus; Pulvis Antimonialis; Syrupus Phosphatum Compositus; Syrupus Phosphatum cum Quinina et Strychnina.

Uses—Precipitated calcium phosphate, on account of its insolubility in water, was used in making medicated waters in preference to magnesium carbonate and other similar substances in the U. S. P. 1890, but has been replaced by purified talc in later revisions of the U. S. P. It is administered largely now in combination with lactic acid and phosphoric acid, for use in cases of defective nutrition, as in the official syrup and in the N. F. emulsion. The dose is from 10 to 30 grains (0.65 to 2 Gm.).

LIQUOR CALCIS SULPHURATÆ. N. F. Solution of Sulphurated Lime

[**Liq. Calc. Sulphurat.**—Solution of Oxysulphuret of Calcium, Vleminckx Solution, Vleminckx Lotion]

	Metric	Alternative
Lime	**165 Gm.**	5 oz. av. 222 gr.
Sublimed Sulphur	**250 Gm.**	8 oz. av. 151 gr.
Water, a sufficient quantity,		
To make about	**1000 cc.**	2 pints

Slake the lime, mix it with the sulphur and add the mixture gradually to 1750 cc. [3½ pints] of boiling water. Boil this mixture, with frequent agitation, until it is reduced to 1000 cc. [2 pints], and maintain this volume, one hour while boiling, by the addition of water from time to time. Cool and strain the mixture and having allowed the solution to become clear by standing in a stoppered bottle, decant the clear brownish liquid, and preserve it in completely filled and well-stoppered bottles.

Solution of Sulphurated Lime is a clear, brownish red liquid with a slight hydrogen sulphide-like odor and an alkaline reaction.

Add to 5 cc. of the Solution an excess of diluted hydrochloric acid: the color changes to a pale yellow, a white precipitate of sulphur appears, and hydrogen sulphide is evolved with effervescence.

Boil the liquid obtained in the foregoing test, filter, and add a slight excess of ammonia T.S., followed by a slight excess of acetic acid: the subsequent addition of 1 cc. of ammonium oxalate T.S. produces a white precipitate.

Uses—Used externally in the treatment of itch, scabies and other skin diseases; for application it is usually diluted with an equal volume or more of water.

LIQUOR HYPOPHOSPHITUM COMPOSITUS. N. F. Compound Solution of Hypophosphites

[Liq. Hypophos. Co.]

	Metric	Alternative
Calcium Hypophosphite	8.500 Gm.	124 gr.
Potassium Hypophosphite	8.500 Gm.	124 gr.
Sodium Hypophosphite	2.200 Gm.	34 gr.
Ferric Hypophosphite	4.400 Gm.	64 gr.
Manganese Hypophosphite	2.200 Gm.	32 gr.
Quinine	2.000 Gm.	29 gr.
Strychnine	0.065 Gm.	1 gr.
Potassium Citrate	8.500 Gm.	124 gr.
Hypophosphorous Acid	7.000 cc.	108 min.
Orange Flower Water	35.000 cc.	1 fl. oz. 58 min.
Glycerin	350.000 cc.	11 fl. oz. 96 min.
Distilled Water, a sufficient quantity,		
To make	1000 cc.	2 pints

Dissolve the calcium, sodium and potassium hypophosphites in 300 cc. [9½ fl. oz.] of distilled water. Dissolve the remaining salts in 250 cc. [8 fl. oz.] of distilled water with the aid of heat and add the hypophosphorous acid in which the quinine and strychnine have previously been dissolved. Mix the two solutions, add the orange flower water and glycerin, and sufficient distilled water to make the product measure 1000 cc. [2 pints]; allow the mixture to stand 12 hours and filter.

Compound Solution of Hypophosphites is a clear, colorless liquid, almost odorless, and with a sweetish, acidulous, and bitter taste, and a slightly acid reaction.

Acidulate 5 cc. of the Solution with acetic acid and add 1 cc. of ammonium oxalate T.S.: a white precipitate is produced. A clean platinum wire dipped in the Solution and then held in a non-luminous flame, shows the characteristic flame of sodium.

When this flame is observed through a blue glass, the potassium flame is recognized.

Acidulate 5 cc. of the Solution with hydrochloric acid and add a few drops of potassium ferrocyanide T.S.: a blue color is observed.

Render 25 cc. of the Solution alkaline with ammonia T.S. and shake out with 10 cc. of ether. Evaporate the ether and apply the thalleioquin test to the residue. It shows the presence of quinine. The liquid which has been extracted with ether is subsequently shaken cut with 10 cc. of chloroform. Evaporate the chloroform, add 0.5 cc. of sulphuric acid to the dry residue and drop in a fragment of a crystal of potassium dichromate. A fugitive purple color is produced, showing the presence of strychnine.

Add to 5 cc. of the Solution, one half cc. of silver nitrate T.S.: a white precipitate is produced, which turns brown and eventually black.

Evaporate 1 cc. of Compound Solution of Hypophosphites almost to dryness and ignite carefully. Dissolve the ash in 10 cc. of distilled water, filter, add 1 Gm. of ammonium persulphate, boil until solution is effected and add 1 cc. of silver nitrate T.S.: a purple color results, indicating the presence of manganese.

Uses—The N. F. solutions of hypophosphites contain no sugar and therefore may be used when sugar is contraindicated. Its use is similar to other hypophosphites in doses of 1 fluidrachm (4 cc.).

LIQUOR PHOSPHATUM ACIDUS. N. F. Acid Solution of Phosphates

[Liq. Phos. Acid.—Solution of Acid Phosphates]

	Metric	Alternative
Precipitated Calcium Carbonate	50 Gm.	1 oz. av. 293 gr.
Magnesium Carbonate	5 Gm.	73 gr.
Phosphoric Acid	120 cc.	3 fl. oz. 403 min.
Distilled Water, a sufficient quantity,		
To make	1000 cc.	2 pints

Mix the phosphoric acid with 700 cc. [22½ fl. oz.] of distilled water and dissolve the carbonates in this mixture. Then add sufficient distilled water to make the product measure 1000 cc. [2 pints], and filter.

Acid Solution of Phosphates is a clear, colorless, odorless liquid, with an acid taste and a strongly acid reaction.

Add to 5 cc. of the Solution an excess of ammonia T.S.: a thick, gelatinous, white precipitate is produced.

Uses—It is used as a tonic and alterative, usually added to nutritive drinks. The dose is 1 fluidrachm (4 cc.).

LIQUOR PHOSPHATUM COMPOSITUS. N. F. Compound Solution of Phosphates

[Liq. Phos. Co.]

	Metric	Alternative
Precipitated Calcium Carbonate	70 Gm.	2 oz. av. 147 gr.
Soluble Ferric Phosphate	35 Gm.	1 oz. av. 74 gr.
Ammonium Phosphate	35 Gm.	1 oz. av. 74 gr.
Sodium Citrate	35 Gm.	1 oz. av. 74 gr.
Citric Acid	120 Gm.	4 oz. av. 2 gr.
Phosphoric Acid	106 cc.	3 fl. oz. 188 gr.
Glycerin	375 cc.	12 fl. oz.
Orange Flower Water	125 cc.	4 fl. oz.
Distilled Water, a sufficient quantity, To make	1000 cc.	2 pints

Dissolve the citric acid and phosphoric acid in 100 cc. [3 fl. oz. 96 min.] of distilled water and gradually add the precipitated calcium carbonate. When the latter is dissolved and effervescence has ceased, add the orange flower water and glycerin, and mix well. Dissolve the ferric phosphate, ammonium phosphate and sodium citrate in 100 cc. [3 fl. oz. 96 min.] of hot distilled water, cool and add to the solution previously prepared. Then add sufficient distilled water to make the product measure 1000 cc. [2 pints], and filter.

Compound Solution of Phosphates is a clear, pale yellow liquid, with an orange flower-like odor, an acid taste and a strongly acid reaction. Add to 5 cc. of the Solution an excess of ammonia T.S.: a thick, gelatinous, pale yellow precipitate is produced.

This preparation was introduced to provide a relatively permanent solution of the phosphates for the extemporaneous preparation of the N. F. syrups which rapidly discolor, due to the caramelization of the sugar by the free acid.

N. F. Preparations—Syrupus Phosphatum Compositus; Syrupus Phosphatum cum Quinina et Strychnina.

Unofficial Salts of Calcium

Calcii Benzoas, $Ca(C_7H_5O_2)_2.3H_2O$ Calcium Benzoate	Soluble white powder or crystals; made by the action of benzoic acid on calcium hydroxide. It is used in preparing certain aromatic ketones and has been employed in medicine as an alterative and antiseptic. Dose, 10 to 30 grains (0.6 to 2 Gm.)
Calcium Chloride Urea, N. N. R. $CaCl_2.4(NH_2)_2CO$ Afenil	Colorless crystals, very soluble in water. Has the same action as calcium chloride. Used intravenously. Dose, 10 cc. of 10 per cent solution by injection. Manufactured by Knoll and Co.
Calcii Hydroxidum, $Ca(OH)_2$ Calcium Hydroxide	A white, dry powder. It is very slightly soluble in water. It is made by the action of water on calcium oxide. Calcium hydroxide is used on a large scale in the manufacture of mortar, cements, calcium salts, and is the active constituent of lime water
Calcii Iodas, $Ca(IO_3)_2.6H_2O$ Calcium Iodate	A white, crystalline powder; slightly soluble in water. It is used as an intestinal antiseptic. Dose, from 3 to 5 grains (0.2 to 0.32 Gm.)
Calcii Iodidum, CaI_2 Calcium Iodide	A yellowish-white powder; gradually decomposed by absorbing moisture and carbon dioxide from the air. It is deliquescent and very soluble in water
Calcii Phenolsulphonas, $Ca(C_6H_5SO_4)_2.H_2O$ Calcium Phenolsulphonate	A white crystalline powder; soluble in water. It is used in medicine as an intestinal antiseptic and astringent. Dose, 5 to 15 grains (0.32 to 1 Gm.)
Calcii Salicylas, $Ca(C_7H_5O_3)_2.2H_2O$ Calcium Salicylate	A white crystalline powder, having an alkaline reaction. It is very slightly soluble in water but readily soluble in carbonated water. It is used in gastroenteritis and the summer diarrhea of children. Dose, 8 to 15 grains (0.5 to 1 Gm.)
Calcii Sulphas, $CaSO_4.2H_2O$ Calcium Sulphate	Commonly called *gypsum*, as it occurs in nature. A white powder, insoluble in water. Plaster of Paris is made from this salt by driving off three-fourths of its water of crystallization. Gypsum is also used as a glaze in paper manufacture and as a polishing powder
Calcii Sulphas Exsiccatus, $CaSO_4.\frac{1}{2}H_2O$ Exsiccated Calcium Sulphate (Plaster of Paris)	A fine, white powder; very slightly soluble in water. When mixed with half its weight of water it forms a smooth paste which rapidly hardens. It is used in decorative and stucco work and in making *plaster of Paris bandages*
Calcii Sulphidum, CaS Calcium Sulphide	Light-gray cubes; slightly soluble in water; dissolved by acids with the evolution of hydrogen sulphide. This compound is used in depilatories and in luminous paint
Calcii Sulphidum Crudum Crude Calcium Sulphide, U. S. P. IX (Calx Sulphurata, Sulphurated Lime)	A pale gray or yellowish powder having a faint odor of hydrogen sulphide. It gradually decomposes on exposure to moist air. It is very slightly soluble in cold water. Sulphurated lime is used as a depilatory and internally for acne, and other skin diseases. It has also been suggested as an antidote to bichloride of mercury. The dose is ½ to 1 grain (0.03 to 0.06 Gm.)

Unofficial Salts of Calcium—*Continued*

Calcii Sulphis, $CaSO_3$ Calcium Sulphite	A white powder, slightly soluble in water but readily soluble in water containing sulphur dioxide. It is used as a disinfectant, an antichlor, and a preservative. Its dose, as an antiseptic, is from 1 to 5 grains (0.06 to 0.32 Gm.)
Calcii Sulphydras, $CaH_2S_2.6H_2O$ Calcium Sulphydrate	Colorless, transparent crystals that decompose in air. It should be kept in well-closed containers. It is soluble in water and is used as a depilatory
Calcii Thiosulphas, $CaS_2O_3.6H_2O$ Calcium Thiosulphate	White crystals that are readily soluble in water. This salt is the commercial source of "hypo" or sodium thiosulphate, since, when treated, in solution, with sodium carbonate it yields the insoluble calcium carbonate and a solution of sodium thiosulphate. In medicine it is used as an internal antiseptic. Dose, 3 to 10 grains (0.2 to 0.65 Gm.)

RADIUM AND ITS DISINTEGRATION PRODUCTS AND COMPOUNDS

Radium is from the Latin "radius", meaning "ray" and indicative of the active emanations, characteristic of this marvelous element. It belongs to the barium group, and has an atomic weight of 226.0. It is a bright white metal, melting at about 700° C.

It was discovered in 1898 by Pierre and Madame Curie, from the concentrates of some of the Austrian uranium mines after the extraction of the uranium from the ore. The principal radium-containing ores are *carnotite* and *pitchblende*. It is possible that radium is a disintegration product of uranium, which is the element possessing the highest atomic weight known to chemistry. Radium has been the key to some of the mysteries of physical chemistry and the composition of the atom.

It exists in very minute amounts in the ores from which it is extracted, only a small fraction of a grain of radium being present in each ton of the ore. This accounts for its extremely high cost, which is approximately $100,000 a gram. There has been extracted and purified, up to the present time, a total of about 200 grams of radium. The insoluble carbonate and sulphate of radium, and the soluble bromide and chloride are the salts most frequently used. Radium and its compounds are used for their radioactivity, which has been defined as "the property of spontaneously emitting radiations, part of which are capable of passing through plates of metal and other substances opaque to ordinary light, and which have the power of discharging electrified bodies". All of the radioactive elements undergo spontaneous disintegration. During this disintegration certain rays are emitted which are known as alpha, beta and gamma rays. The *alpha rays* are material particles of atomic size, carrying a positive electric charge. After losing this charge the particles become atoms of helium. This transformation, which has been substantiated by much experimental evidence, is a true example of the transformation of one element into another. The *beta rays* are subatomic in size, are not material but consist of electrons, and are identical with the cathode rays of an X-ray tube. The *gamma rays* are like light rays of short wave length. Radioactivity is therefore due to an atomic explosion, the particles and rays being emitted with a speed almost as great as that of light, which travels 186,000 miles a second.

The energy that is thus represented is tremendous. It is stated that the interatomic energy of a gram of radium, if it could be harnessed, would yield power enough to drive a huge ocean liner across the Atlantic Ocean.

In the transformations of radium a series of products is formed. The first of these is the gas *niton*, with a density of over one hundred times that of the element hydrogen. In less than four days, half of this emanation disintegrates

with the formation of *Radium A*, and the emission of alpha rays. Radium A is identical with *polonium*. By the successive loss of alpha and beta rays other disintegration products are produced. Gamma rays usually accompany the emission of a beta particle. The *Radium C* group yields the most penetrating rays and those which are most useful of the therapeutic properties of radium. The following table from the N. N. R. of 1925 shows a complete list of the disintegration products of radium. It is estimated that the natural disintegration of radium is taking place at such a rate that in 1700 years half of any given quantity will have changed.

Radium and Its Disintegration Products

Substance	Chemical Nature	Atomic Weight	Valence	Half Value Periods	Rays
Radium	Metal	226	2	1,780 yrs.	Alpha
Radium emanation	Inert gas	222	0	3.85 days	Alpha
Radium A	Solid non-metal identical with polonium	218	6	3.0 min.	Alpha
Radium B	Identical with lead	214	4	26.7 min.	Beta, Gamma
Radium C_1	Identical with bismuth	214	5	19.5 min.	Alpha, Beta, Gamma
Radium C_2	Identical with thallium	210	3	1.4 min.	Beta, Gamma
Radium C	Identical with polonium	214	6	10^{-6} sec.	Alpha
Radium D	Identical with lead	210	4	15.8 yrs.	Beta, Gamma
Radium E	Identical with bismuth	210	5	4.85 days	Beta, Gamma
Radium F	Polonium	210	6	136 days	Alpha

Radium and its products are valued in mathematical terms of radioactivity expressed in units of distinctive character created for this purpose. The ionization or dissociation produced in certain gases by the influence of radioactivity is used as a basis of determining activity.

The units commonly employed are as follows:

1. *Milligrams* and *micrograms* (a microgram is 0.001 mgm.).

2. *Curies, millicuries* and *microcuries.* The curie is the quantity of emanation represented by 1 Gm. of radium, in equilibrium with its disintegration products (a millicurie is 0.001 curie, a microcurie is 0.000001 curie).

3. *Mache units.* A mache unit is the equivalent of 1/2700 of one microcurie of radium emanation. The use of this latter unit is being discouraged.

Purchasers and users of radium salts may have their radioactive value determined upon application to the U. S. Bureau of Standards.

Radium emanation has been termed "radon" in scientific literature. It may be collected and purified and kept in sealed glass tubes which are then kept in a metal container until needed for use. The emanation is sometimes dissolved in water for use.

Radium therapy requires the knowledge of skilled specialists. Pharmacists are sometimes called upon to supply radium salts or radium emanation devices.

For detailed descriptions of these forms, see N. N. R. 1925.

Barium, Ba.; 137.37

Barium takes its name from a Greek word meaning "heavy". This element furnishes but one official salt, the sulphate, although several others are found among the reagents—the chloride, the nitrate, and also the hydroxide. Barium dioxide was formerly designated in the official process for making solution of hydrogen dioxide, but since the U. S. P. no longer gives a method for preparing this solution the dioxide is not given official recognition, though it is used in enormous quantities in the production of hydrogen dioxide and is now manufactured in the United States. Barium occurs abundantly as *heavy spar*, a sulphate, and as *witherite*, a carbonate. It is a malleable metal, having a yellowish-white luster, decomposing water, and gradually oxidizing in the air.

Tests for Salts of Barium

Barium—Solutions of barium salts yield a white precipitate with diluted sulphuric acid. This precipitate is insoluble in hydrochloric or nitric acid. Barium salts impart a green color to a non-luminous flame.

BARII SULPHAS. U. S. Barium Sulphate

Barium Sulphate [$BaSO_4 = 233.43$], freed from soluble barium salts.

The Pharmacopœia adds the following special note to emphasize to both the physician and the pharmacist the danger from mistakes when prescribing this salt.

Caution—In prescribing Barium Sulphate the title should never be abbreviated, to avoid confusion with the poisonous barium sulphide or sulphite.

Other salts of barium, especially the sulphide are employed for legitimate purposes and are frequently sold by the manufacturer or wholesale druggist, but they are so rarely prescribed by the physician that it is a safe rule never to dispense any other salt than the *sulphate* even should the doctor write for "Bar. Sulph."

Preparation—While the mineral *heavy spar* or *barytes* consists of crude barium sulphate this is usually ground to powder and strongly heated in contact with charcoal or some other carbonaceous substance, which removes the oxygen as carbonic oxide and converts the sulphate into sulphide, as indicated by the following equation:

$$\underset{\text{barium sulphate}}{BaSO_4} + \underset{\text{carbon}}{C_4} = \underset{\text{carbon monoxide}}{4CO} + \underset{\text{barium sulphide}}{BaS}$$

In preparing the purified sulphate the sulphide, which contains $Ba(SH)_2$ and $Ba(OH)_2$, is mixed with water and treated with dilute sulphuric acid, when the extremely insoluble barium sulphate separates and is collected, purified, and dried. The equation is as follows:

$$\underset{\text{barium hydroxide}}{Ba(OH)_2} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{barium sulphate}}{BaSO_4} + \underset{\text{water}}{2H_2O}$$

It may also be prepared by precipitating a solution of barium chloride by the addition of sodium sulphate, as indicated in the following equation:

$$\underset{\text{barium chloride}}{BaCl_2} + \underset{\text{sodium sulphate}}{Na_2SO_4} = \underset{\text{barium sulphate}}{BaSO_4} + \underset{\text{sodium chloride}}{2NaCl}$$

Commercial grades of the precipitated barium sulphate, under the names *permanent white* or *blanc fixé*, are extensively used as a paint pigment, fre-

quently replacing white lead, chiefly because it does not darken with sulphides but also because it is less expensive.

Description and Physical Properties—A fine, white, odorless, tasteless and bulky powder, free from grittiness.

Barium Sulphate is insoluble in water, in organic solvents, and in aqueous solutions of acids and alkalies.

Tests for Identity—Mix 0.5 Gm. of Barium Sulphate with 2 Gm. each of anhydrous sodium carbonate and anhydrous potassium carbonate, heat the mixture in a crucible until fusion is complete, treat the resulting fused mass with hot water, and filter. Acidulate a portion of the filtrate with hydrochloric acid, and add 1 cc. of barium chloride T.S.: a white precipitate forms.

Dissolve in acetic acid a portion of the well-washed precipitate, obtained in the preceding test: the solution responds to the reactions for barium, page 686.

Tests for Purity—Boil 10 Gm. of Barium Sulphate with a mixture of 10 cc. of diluted hydrochloric acid and 90 cc. of distilled water for ten minutes, and add sufficient distilled water to restore the original volume. During boiling there should be no evolution of hydrogen sulphide, recognizable by the darkening of lead acetate paper exposed to the vapor (*sulphide*). Cool the mixture, and filter through paper which has been previously washed with a solution of 10 cc. of diluted hydrochloric acid and 90 cc. of distilled water, returning the first portions if necessary until a perfectly clear filtrate is obtained. Evaporate 50 cc. of the filtrate to dryness on a water bath, add two drops of hydrochloric acid and 10 cc. of hot distilled water. Filter through acid-washed paper, wash with 10 cc. of hot distilled water, and evaporate the combined filtrate and washings to dryness in a tared dish on a water bath. The residue, when dried to constant weight at from 100° to 110° C., should not be more than 0.3 per cent (*limit of acid-soluble substances*). Treat this residue with 10 cc. of distilled water, filter the solution through a filter previously washed with a mixture of 10 cc. of diluted hydrochloric acid and 90 cc. of distilled water, and add 0.5 cc. of diluted sulphuric acid: no turbidity should develop within one-half hour (*soluble barium salts*).

Boil 1 Gm. of Barium Sulphate with a mixture of 3 cc. of nitric acid and 5 cc. of distilled water during five minutes. Filter, and add to the warm filtrate an equal volume of ammonium molybdate T.S.: no yellow precipitate is formed (*phosphate*).

Digest 1 Gm. of Barium Sulphate with 20 cc. of distilled water during five minutes: the latter remains neutral to litmus paper (*free acid or alkali*).

Boil 5 Gm. of Barium Sulphate with 50 cc. of diluted acetic acid, and filter while hot: the filtrate meets the requirements of the test for *heavy metals*, page 1519.

Triturate 2 Gm. of Barium Sulphate with 5 cc. of concentrated hydrochloric acid, and add 10 cc. of a freshly made, saturated solution of stannous chloride: no dark coloration occurs within one-half hour (*arsenic*).

Uses—Barium sulphate is used in roentgenography for the purpose of making the intestinal tract opaque to the X-ray so that it may be photographed. As the amount required is large (two to eight ounces, and as soluble salts of barium are extremely poisonous, it is highly important to be sure that the sulphate dispensed is of U. S. P. quality. Very rigid tests are provided for the exclusion of soluble barium salts.

The N. N. R. describes the method of administration as follows:

For the Roentgen-Ray Examination of the Stomach—The evening before the examination, the patient receives 1 fluidounce of castor oil. In the morning an ordinary portion of wheat-meal porridge, with which 2 ounces of barium sulphate has been well mixed, together with a little sugar and cream, is administered by mouth. The patient is then directed to abstain from further food. The examination is made six hours later.

For the Roentgen-Ray Examination of the Colon—An enema consisting of 16 ounces of mucilage of acacia, 3 pounds of condensed milk, and 8 ounces of barium sulphate is warmed to body temperature and injected into the rectum from a height of from 3 to 6 feet (90 to 170 cm.). The examination is made with a fluoroscope while the injection is passing into the rectum.

Unofficial Salts of Barium

Barii Acetas, $Ba(C_2H_3O_2)_2.H_2O$ Barium Acetate	A poisonous, white, crystalline powder; soluble in water. It is chiefly used as a chemical reagent
Barii Benzoas, $Ba(C_7H_5O_2)_2.2H_2O$ Barium Benzoate	Small, colorless, laminar crystals; soluble in water. It is used as a heart stimulant, and is very poisonous
Barii Bromidum, $BaBr_2.2H_2O$ Barium Bromide	Poisonous, colorless crystals; soluble in water. It is used as a reagent and in the manufacture of other bromides

Unofficial Salts of Barium—*Continued*

Barii Carbonas, $BaCO_3$ Barium Carbonate	An insoluble, white powder, readily decomposed by acids with the evolution of carbon dioxide. It is made by precipitation and occurs as a native mineral called *witherite*. Barium Carbonate is used in the preparation of other barium compounds. It is used as a rat poison
Barii Chloridum, $BaCl_2.2H_2O$ Barium Chloride (See U. S. P. Test Solution)	Colorless, flat crystals; poisonous, and readily soluble in water. Barium chloride is used as a chemical reagent, in boiler compounds, in the leather industry, in rat and vermin poisons, and in medicine as a cardiac tonic and alterative. The dose is from ½ to 1½ grains (0.03 to 0.1 Gm.)
Barii Chromas, $BaCrO_4$ Barium Chromate	A heavy, yellow, crystalline powder; insoluble in water. It is poisonous. It is called yellow ultramarine and is used as a yellow paint pigment, and in Swedish matches
Barii Dioxidum, BaO_2 Barium Dioxide	A white or grayish-white powder. It is decomposed by water, forming the hydrated barium dioxide. It is poisonous. Barium dioxide is largely used in preparing medicinal peroxide of hydrogen; also in the manufacture of oxygen by the "Brin process", and as a bleaching agent
Barii Hydroxidum, $Ba(OH)_2.8H_2O$ Barium Hydroxide (See U. S. P. Test Solution)	A poisonous, white powder; soluble in water forming a solution known as baryta water. Barium hydroxide absorbs carbon dioxide from the air, hence it should be kept well stoppered. It is used as a reagent, in the manufacture of barium salts and in refining vegetable and animal oils
Barii Iodidum, $BaI_2.2H_2O$ Barium Iodide	Poisonous, colorless crystals that decompose and redden on exposure to air. It is readily soluble in water, and is used as an alterative. The dose is from one tenth to one half grain (0.006 to 0.03 Gm.)
Barii Nitras, $Ba(NO_3)_2$ Barium Nitrate (See U. S. P. Test Solution)	Lustrous, white, poisonous crystals or a white powder, soluble in water. It is chiefly used in pyrotechnics, as *green fire*, in green railroad torches and in marine signals
Barii Sulphidum, BaS Barium Sulphide	A yellowish-green or gray powder; soluble in water and dissolved by hydrochloric acid with the evolution of hydrogen sulphide. It is poisonous. Barium sulphide is used as a depilatory, in the manufacture of other barium compounds, and for generating pure hydrogen sulphide for analytical purposes

Strontium, Sr; 87.63

Strontium is named after Strontian, a village in Scotland where *strontianite* was first found. It enters into one official salt. It occurs in nature chiefly as sulphate and carbonate. It is a yellow metal, sp. gr. 2.5; malleable, but somewhat harder than lead. Its use in medicine is due to Laborde's demonstration in 1890 that its salts are not poisonous in ordinary doses, but, in certain cases, beneficial.

Tests for Salts of Strontium

An incompatibility frequently encountered in connection with the dispensing of soluble strontium salts occurs when a soluble carbonate is present, as in aromatic spirit of ammonia, which causes the precipitation of strontium carbonate, or when a soluble citrate is present, as in solution of potassium or sodium citrate which causes the precipitation of strontium citrate. Such a prescription must be dispensed with a "shake label".

Strontium compounds moistened with hydrochloric acid impart a crimson color to a non-luminous flame. Calcium sulphate T.S. produces a white precipitate with solutions of strontium salts.

STRONTII SALICYLAS. U. S. Strontium Salicylate

[Stront. Salicyl.]

Strontium Salicylate, when dried to constant weight over sulphuric acid, contains not less than 99 per cent of $Sr(C_7H_5O_3)_2.2H_2O$ (397.81).

Preparation—It may be made by decomposing strontium carbonate with a strong, hot solution of salicylic acid, filtering, and crystallizing.

$$\underset{\text{strontium carbonate}}{SrCO_3} + \underset{\text{salicylic acid}}{2HC_7H_5O_3} = \underset{\text{strontium salicylate}}{Sr(C_7H_5O_3)_2} + \underset{\text{water}}{H_2O} + \underset{\text{carbon dioxide}}{CO_2}$$

Description and Physical Properties—A white, odorless, crystalline powder, having a somewhat sweet, saline taste.

One Gm. of Strontium Salicylate is soluble in 19 cc. of water and in 61 cc. of alcohol, at 25° C. One Gm. is soluble in 3.7 cc. of boiling water and in 14 cc. of boiling alcohol.

Tests for Identity—When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaving a residue of strontium carbonate and carbon.

An aqueous solution of the salt (1 in 20) responds to the reactions for strontium, page 688, and for salicylates, page 826.

Test for Purity—An aqueous solution of the salt (1 in 30) is colorless.

Add 1 cc. of diluted sulphuric acid to 10 cc. of an aqueous solution of Strontium Salicylate (1 in 50), and filter: the filtrate meets the requirements of the test for *heavy metals*, page 1519.

Agitate 2 Gm. of Strontium Salicylate with 10 cc. of diluted acetic acid, heat the mixture, cool, and filter: the filtrate upon the addition of 5 drops of potassium dichromate T.S. does not become cloudy within three minutes (*barium*).

Assay—Place about 2 Gm. of Strontium Salicylate, previously dried to constant weight over sulphuric acid and accurately weighed, in a tared platinum crucible, and thoroughly carbonize it at a temperature not exceeding red heat. Dissolve the residue in 30 cc. of half-normal hydrochloric acid, and submit it to residual titration with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of half-normal hydrochloric acid corresponds to 0.09945 Gm. of $Sr.(C_7H_5O_3)_2.2H_2O$.

This assay is explained on page 1456.

Preserve in well-closed containers, protected from heat and light.

Uses—Strontium salicylate is used for rheumatism in place of sodium salicylate in doses of ten to fifteen grains (0.65 to 1 Gm.). Its uses are similar to those of the sodium salt.

Unofficial Salts of Strontium

Strontii Bromidum, $SrBr_2.6H_2O$, U. S. P. IX Strontium Bromide	Colorless, transparent crystals; very soluble in water. It is hygroscopic in moist air but effloresces when exposed to dry air. It is used in epilepsy and other nervous diseases. The dose is from 15 to 30 grains (1 to 2 Gm.)
Strontii Carbonas, $SrCO_3$, N. F. IV Strontium Carbonate	This salt occurs in nature as the mineral *strontianite*. It may be prepared by precipitating any soluble salt of strontium with sodium carbonate. It is a white powder; insoluble in water. It is used in pyrotechnics, in the manufacture of iridescent glass, and in producing other salts of stronium. It has been used in the preparation of the compound elixir of formates
Strontii Chloridum, $SrCl_2$ Strontium Chloride	White, crystalline needles having a sharp, bitter taste. It is readily soluble in water and is used in the manufacture of strontium carbonate and in producing red fire
Strontii Hydroxidum, $Sr(OH)_2$ Strontium Hydroxide	Colorless, deliquescent crystals; slightly soluble in water. It is used in the manufacture of other strontium compounds, but chiefly in the sugar industry, to separate crystallizable sugar from molasses
Strontii Iodidum, $SrI_2.6H_2O$, U. S. P. IX Strontium Iodide	A white, deliquescent granular powder that becomes yellow on exposure to air and light. It is very soluble in water. Strontium Iodide is sometimes used instead of potassium iodide, as it is believed to be less irritating to the intestinal tract, or less depressing to the general nutrition. The dose is from 5 to 20 grains
Strontii Lactas, $Sr(C_3H_5O_3)_2.3H_2O$ Strontium Lactate	A white granular powder; soluble in water and having a slightly bitter taste. It is used as a tonic, diuretic, anthelmintic, and in the treatment of nephritis. The dose is from 5 to 30 grains (0.3 to 2 Gm.)
Strontii Nitras, $Sr(NO_3)_2$ Strontium Nitrate	A soluble white powder. It is used in pyrotechnics, especially in the production of *red fire*, marine signals, and railroad flares
Strontii Oxidum, SrO Strontium Oxide	A grayish-white, porous, caustic mass. It is soluble in water with the evolution of heat, forming strontium hydroxide.
Strontii Sulphas, $SrSO_4$ Strontium Sulphate	A white, crystalline powder; very slightly soluble in water. This compound occurs in nature as the mineral *celestite*. It is chiefly used in pyrotechnics

CHAPTER LI

ZINC, ALUMINUM, THORIUM, CERIUM, AND CADMIUM

Zn; 65.37. Al; 27.0. Th; 232.15. Ce; 140.25. Cd; 112.40

THESE metals are grouped together on account of the similarity in some of their physical properties, rather than because of the chemical analogies existing between them.

Metallic zinc (Zn = 65.37) of not less than 99 per cent purity was official in the U. S. P. IX for preparing solution of zinc chloride. The process was not retained in the U. S. P. X and zinc was also omitted. A zinc of special purity for the arsenic test, will be found among the reagents (see Chapter XCII). Zinc is sometimes used in preparing hydrogen.

Zinc, Zn; 65.37

Tests for Zinc Salts

In alkaline solutions, zinc salts yield a white precipitate with hydrogen sulphide. This precipitate is insoluble in acetic acid but is dissolved by diluted hydrochloric acid. Ammonium sulphide produces a similar precipitate in neutral or alkaline solutions. Zinc salts in solution yield with potassium ferrocyanide T.S. a white precipitate which is insoluble in diluted hydrochloric acid.

History—*Zinc* from "zinken", a word used by Paracelsus who regarded the element as a semi-metal. Although the alloy of zinc and copper, called brass, was known to the Romans, the metal zinc does not appear to have been separated and described until the sixteenth century. Its identity was a mystery for several centuries. Paracelsus thought it was a form of copper, others thought it was altered mercury, tin, or bismuth.

Preparation—Zinc is obtained by roasting *smithsonite*, impure zinc carbonate, with charcoal, in powder, and collecting the zinc by distillation, the vapors being conducted into water, where the zinc is condensed. It is also obtained in large quantities from *zinc blende*, which is a zinc sulphide. The ore containing the sulphide is first concentrated by a flotation process. The sulphide is then converted into oxide by roasting.

$$\underset{\text{zinc sulphide}}{ZnS} + 3O = \underset{\text{zinc oxide}}{ZnO} + \underset{\text{sulphur dioxide}}{SO_2}$$
(oxygen)

The oxide is then reduced to metal by heating with carbon.

$$\underset{\text{zinc oxide}}{ZnO} + \underset{\text{carbon}}{C} = \underset{\text{zinc}}{Zn} + \underset{\text{carbon monoxide}}{CO}$$

In the roasting process for treating this ore, the sulphur dioxide which is produced is converted into sulphuric acid.

Zinc is bivalent, and combines with oxygen, chlorine, and phosphorus, forming zinc oxide, chloride, and phosphide, and with numerous acids to form salts. A very pure grade of zinc is now made by electrolysis. The U. S. P. IX description and tests for zinc were as follows:

Description and Tests—Zinc is a bluish-white metal, showing a crystalline fracture. In thin sheets, or in irregular, granulated pieces, or molded into thin pencils, or in powder. It has a specific gravity ranging from 6.9, when it is cast, to 7.2 after it is rolled.

It is dissolved by diluted sulphuric or hydrochloric acid with the evolution of hydrogen, usually leaving some insoluble residue.

Impurities and Tests for Impurities—*Sulphur*—Add 1 Gm. of Zinc to 25 cc. of diluted sulphuric acid; the liberated hydrogen does not have a disagreeable odor, nor does it color a strip of paper moistened with lead acetate T.S.

Arsenic, Antimony, and Phosphorus—With silver nitrate T.S. the filtered solution is colorless, and yields a white, gelatinous precipitate with potassium ferrocyanide T.S. and a white precipitate with ammonium sulphide T.S.

Assay—Dissolve about 1 Gm. of Zinc, accurately weighed, in a slight excess of hydrochloric acid and add sufficient distilled water to make 100 cc. Dilute 10 cc. of the clear solution with distilled water to make 100 cc., render it slightly alkaline with ammonia water and subsequently treat it as directed in the assay for *Zinci Acetas* (page 691), for the determination of zinc oxide. Each Gm. of Zinc corresponds to not less than 1.232 Gm. of ZnO.

Zinc may also be assayed by the Electrolytic method.

ZINCI ACETAS. U. S. Zinc Acetate

[Zinc. Acet.]

Zinc Acetate contains not less than 83.16 per cent and not more than 87.32 per cent of $Zn(C_2H_3O_2)_2$ (183.44), corresponding to not less than 99.5 per cent of the crystallized salt $[Zn(C_2H_3O_2)_2.2H_2O = 219.47]$.

Preparation—This salt may be made by adding 2 parts of zinc oxide to 8½ parts of acetic acid, and 5 parts of distilled water; then digesting the mixture for half an hour, heating to the boiling point, filtering while hot, crystallizing, draining the crystals in a funnel, and drying them on bibulous paper. An additional quantity of crystals may be obtained by evaporating the mother liquor to one-half, slightly acidulating with acetic acid, and crystallizing.

The reaction is expressed by the following equation:

$$\underset{\text{zinc oxide}}{ZnO} + \underset{\text{acetic acid}}{2HC_2H_3O_2} = \underset{\text{zinc acetate}}{Zn(C_2H_3O_2)_2} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—Soft, white, six-sided, monoclinic plates, having a pearly luster, a faintly acetous odor, and, in dilute solutions, an astringent, metallic taste. When exposed to air, the salt gradually effloresces and loses some of its acid.

One Gm. of Zinc Acetate is soluble in 2.3 cc. of water and in 30 cc. of alcohol, at 25° C. One Gm. is soluble in 1.6 cc. of boiling water and in about 1 cc. of boiling alcohol.

When heated, Zinc Acetate is partially fused, losing water and acetic acid. At a higher temperature it is decomposed, with the evolution of inflammable and empyreumatic vapors, and leaves a residue consisting chiefly of zinc oxide.

Tests for Identity—An aqueous solution of the salt responds to the reactions for zinc, page 690, and for acetates, page 800.

Tests for Purity—An aqueous solution of the salt is neutral or slightly acid to litmus paper.

A 10 cc. portion of an aqueous solution of the salt (1 in 50) to which 1 cc. of hydrochloric acid has been added, meets the requirements of the test for *heavy metals*, page 1519.

An aqueous solution of the salt meets the requirements of the test for *arsenic*, page 1512.

Assay—Dissolve about 1 Gm. of Zinc Acetate, accurately weighed, in 100 cc. of distilled water, render the solution slightly alkaline with ammonia T.S., and warm to 80° C. Completely precipitate the zinc as zinc sulphide by the addition of ammonium sulphide T.S. and warm the liquid on a water bath until the precipitate settles. Collect the latter on a filter, wash it with distilled water containing a few drops of ammonium sulphide T.S. then dissolve it in hot, dilute nitric acid (1 in 3), evaporate the solution to dryness in a tared dish, ignite the residue, and weigh it as zinc oxide. The weight of zinc oxide obtained, multiplied by 2.254, indicates its equivalent in $Zn(C_2H_3O_2)_2$. Each Gm. of Zinc Acetate corresponds to not less than 0.369 Gm. and not more than 0.387 Gm. of ZnO.

This assay is explained on page 1478.

Zinc Acetate may also be assayed by the electrolytic method, page 1515.

Preserve in well-closed containers.

Uses—Zinc acetate is used locally for its astringent effect, in eye washes, injections, etc. If used internally, the dose is two grains (0.125 Gm.).

ZINCI CHLORIDUM. U. S. Zinc Chloride
[Zinc. Chlor.]

Zinc Chloride contains not less than 95 per cent of $ZnCl_2$ (136.29).

Preparation—Zinc chloride is easily prepared by digesting metallic zinc in hydrochloric acid and evaporating the solution to dryness;

$$\underset{\text{zinc}}{2Zn} + \underset{\substack{\text{hydrochloric}\\\text{acid}}}{4HCl} = \underset{\substack{\text{zinc}\\\text{chloride}}}{2ZnCl_2} + \underset{\text{hydrogen}}{4H}$$

or, preferably, by evaporating the official solution of zinc chloride.

It may also be prepared by decomposing either zinc oxide or zinc carbonate with the appropriate amount of hydrochloric acid.

Description and Physical Properties—A white, or nearly white, odorless, granular powder, or in porcelain-like masses, or molded into pencils. It is very deliquescent.

One Gm. of Zinc Chloride is soluble in 0.25 cc. of water and in about 1.3 cc. of alcohol, at 25° C. It is soluble in 2 parts of glycerin.

When heated to about 260° C., Zinc Chloride fuses to a clear liquid. At a higher temperature (about 730° C.), it is partly volatilized in dense, white fumes, and partly decomposed, leaving a residue of zinc oxide.

An aqueous solution of the salt (1 in 10) is acid to litmus paper.

Tests for Identity—An aqueous solution of the salt responds to the reactions for zinc, page 690, and for chlorides, page 567.

Tests for Purity—Mix an aqueous solution of Zinc Chloride (1 in 20) with an equal volume of alcohol: a single drop of hydrochloric acid is sufficient to render 10 cc. of the mixture perfectly clear (*oxychloride*).

Completely precipitate the zinc from a solution of 1 Gm. of the salt in 50 cc. of distilled water by means of ammonium sulphide T.S., filter, evaporate the filtrate, and ignite gently: the weight of the residue does not exceed 0.004 Gm.

A 10 cc. portion of an aqueous solution of the salt (1 in 50), to which 1 cc. of diluted hydrochloric acid has been added, meets the requirements of the test for *heavy metals*, page 1519.

Add ammonium carbonate T.S. in small portions, to an aqueous solution of Zinc Chloride (1 in 20): the precipitate produced is white, and redissolves completely in an excess of the reagent.

Add sufficient sodium hydroxide T.S. to 5 cc. of an aqueous solution of the salt (1 in 10) to redissolve the precipitate which first forms, and then warm the solution: the odor of ammonia is not perceptible (*ammonium salts*).

One Gm. of Zinc Chloride shows no more *sulphate* than corresponds to 0.3 cc. of fiftieth-normal sulphuric acid, page 1520.

Assay—Proceed as directed under the assay for chlorides, page 1514, using about 0.3 Gm. of Zinc Chloride, accurately weighed in a stoppered weighing bottle. Each cc. of tenth-normal silver nitrate corresponds to 0.006815 Gm. of $ZnCl_2$.

Zinc Chloride may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1463.

Preserve in small, glass-stoppered bottles.

Uses—Zinc chloride in dilute solution is used as an antiseptic and astringent (see Liquor Zinci Chloridi, below). Mixed with flour and water, it is used as an escharotic.

LIQUOR ZINCI CHLORIDI. U. S. Solution of Zinc Chloride
[Liq. Zinc. Chlor.]

Solution of Zinc Chloride is an aqueous solution containing not less than 48.5 per cent and not more than 52 per cent of $ZnCl_2$ (136.29).

The following method for its preparation was official in the U. S. P. IX:

	Metric	Alternative
Zinc, granulated	**240 Gm.**	6 oz. av. 84 gr.
Hydrochloric Acid	**840 Gm.**	21 oz. av. 293 gr.
Nitric Acid	**12 Gm.**	135 gr.
Precipitated Zinc Carbonate	**12 Gm.**	135 gr.
Distilled Water, a sufficient quantity,		
To make	**1000 Gm.**	1 pint

Add the hydrochloric acid gradually to the zinc and 250 cc. [4 fl. oz.] of distilled water contained in a glass or porcelain vessel, and allow the mixture to stand until the reaction ceases and the acid is saturated. Then pour off the liquid, add the nitric acid and heat the mixture at a temperature not exceeding 115° C. until a portion, when removed and cooled, solidifies. Allow it to cool, and dissolve the solidified mass in sufficient distilled water to make the product weigh 1000 Gm. [or measure, 1 pint]. Then add the precipitated zinc carbonate, agitate the mixture occasionally during twenty-four hours, and set it aside until it has become clear by subsidence. Separate the clear solution by decantation or by means of a siphon, and preserve it in tightly stoppered bottles.

When zinc is treated with hydrochloric acid, hydrogen is evolved and zinc chloride is produced according to the equation given on page 692.

Zinc is almost invariably contaminated with iron, and more or less ferrous chloride is present in the first solution. Nitric acid is added, and the solution is evaporated to dryness. The iron salt is thus oxidized, and it is then precipitated by the addition of zinc carbonate, the insoluble ferric hydroxide and carbonate, with any excess of zinc carbonate, being filtered out.

Description and Physical Properties—A clear, colorless or slightly yellow, odorless, caustic liquid. It is strongly acid to litmus paper.

Specific gravity: about 1.548 at 25° C.

Tests for Identity and Purity—Solution of Zinc Chloride responds to the reactions for zinc, page 690, and for chlorides, page 567, and meets the requirements of the tests for purity for an aqueous solution of the salt under *Zinci Chloridum*, when taken in proportionate amount.

Assay—Place in a tared flask about 0.5 cc. of Solution of Zinc Chloride, weigh accurately, and proceed as directed under the assay for chlorides, page 1514. Each cc. of tenth-normal silver nitrate corresponds to 0.006815 Gm. of $ZnCl_2$.

This assay is explained on page 1463.

Uses—This solution, sometimes called *Burnett's disinfecting fluid*, is used principally as an antiseptic and astringent. Among its advantages, absence of odor is one of the most prominent.

ZINCI OXIDUM. U. S. Zinc Oxide
[Zinc. Oxid.]

Zinc Oxide, when freshly ignited, contains not less than 99 per cent of ZnO (81.37).

Preparation—Zinc oxide may be prepared by exposing precipitated zinc carbonate, in a shallow vessel, to a low red heat until the water and carbon dioxide are wholly expelled.

$$\underset{\text{zinc carbonate}}{2ZnCO_3.3Zn(OH)_2} = \underset{\substack{\text{zinc}\\\text{oxide}}}{5ZnO} + \underset{\substack{\text{carbon}\\\text{dioxide}}}{2CO_2} + \underset{\text{water}}{3H_2O}$$

Commercial zinc oxide is made on the large scale by roasting *calamine* and coal, ground together, in a furnace of peculiar construction, and separating the impurities by blowing the mixed vapors up a large tower, allowing the heavier particles to subside in the tower, and then by a powerful draught blowing the zinc oxide into a room containing muslin bags, where the oxide is deposited. It is also prepared by heating metallic zinc in earthenware retorts until the zinc vapor ignites in contact with the air. The resulting oxide is then conducted into large chambers, where it is deposited.

$$\underset{\text{zinc}}{2Zn} + \underset{\text{oxygen}}{O_2} = \underset{\text{zinc oxide}}{2ZnO}$$

This kind of zinc oxide will not usually conform to the official tests; it is generally very white and filled with hard lumps, which are difficult to reduce to powder. The official powder has a marked cream tint, and can be mixed with ointment so that a smooth preparation is easily made without trituration. (See Unguentum Zinci Oxidi.)

Description and Physical Properties—A very fine, odorless, amorphous, white or yellowish-white powder, free from gritty particles. It gradually absorbs carbon dioxide from the air.

Zinc Oxide is insoluble in water and in alcohol. It dissolves in dilute acids, in ammonia T.S., and in ammonium carbonate T.S.

Tests for Identity—When strongly heated, it assumes a yellow color which disappears on cooling.

A solution of Zinc Oxide in a slight excess of diluted hydrochloric acid responds to the reactions for zinc, page 690.

Tests for Purity—Mix 1 Gm. of Zinc Oxide in a flask with 10 cc. of boiling, distilled water and add 2 drops of phenolphthalein T.S.: not more than 1 cc. of tenth-normal hydrochloric acid is required to discharge any red color that may be produced (*alkali*).

Mix 2 Gm. of Zinc Oxide with 10 cc. of distilled water, add 30 cc. of diluted sulphuric acid, and heat on a water bath with constant stirring: no effervescence occurs (*carbonate*), and the resulting solution is clear and colorless. Five cc. portions of the cooled solution yield white precipitates with potassium ferrocyanide T.S. or with sodium sulphide T.S. (*iron and many other metals*).

Add 2 Gm. of Zinc Oxide to 20 cc. of distilled water, and after stirring well, add 5 cc. of glacial acetic acid, and warm upon a water bath until solution is effected: the addition of 5 drops of potassium chromate T.S. produces no turbidity or precipitate (*lead*).

Assay—Digest about 1.5 Gm. of freshly ignited Zinc Oxide, accurately weighed, with 50 cc. of normal sulphuric acid until solution is complete. Then titrate the excess of sulphuric acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.04069 Gm. of ZnO.

This assay is explained on page 1457.

Zinc Oxide may also be assayed by the electrolytic method, page 1515.

U. S. P. Preparation—Unguentum Zinci Oxidi.

N. F. Preparations—Glycerogelatinum Zinci Durum; Glycerogelatinum Zinci Molle; Linimentum Calaminæ; Lotio Calaminæ; Mulla Zinci; Pasta Resorcinolis Fortior; Pasta Resorcinolis Mitis; Pasta Zinci; Pasta Zinci Mollis; Pasta Zinci Sulphurata; Unguentum Picis Compositum; Unguentum Resorcinolis Compositum.

History—The oxide of zinc was called by many curious names during its early history. *Pompholyx, nihil album, lana philosophica* and *flores zinci* are the principal examples of these.

Uses—Zinc oxide is chiefly used externally as a desiccant, and protective to inflamed surfaces; it may be dusted on the part or used in the form of an ointment. It is occasionally given internally in diarrhea.

ZINCI STEARAS. U. S. Zinc Stearate

[Zinc. Stear.]

Zinc Stearate is a compound of zinc with stearic acid and variable proportions of palmitic acid, corresponding to not less than 13 per cent and not more than 15.5 per cent of ZnO.

Preparation—Dissolve 10.1 Gm. of monohydrated sodium carbonate in 1000 cc. of distilled water, add 46.4 Gm. of stearic acid, heat the mixture until the reaction is complete, add 1000 cc. of hot distilled water and adjust the temperature to 50° C. Then dissolve 17.9 Gm. of zinc acetate in 1250 cc. of warm distilled water, adjust the temperature of the solution to 50° C. and pour this solution into the sodium stearate solution just prepared, stirring constantly. Collect the precipitate on a strainer, wash thoroughly, and dry.

Description and Physical Properties—A fine, white, bulky powder, free from grittiness, and having a faint characteristic odor.

Zinc Stearate is insoluble in water, alcohol, and ether.

When heated, the salt fuses. At a higher temperature it is decomposed, giving off inflammable vapors and the odor of burning fat, and finally leaving a residue consisting chiefly of zinc oxide.

Tests for Identity—Heat 1 Gm. of Zinc Stearate with a mixture of 25 cc. of distilled water and 5 cc. of hydrochloric acid: stearic acid is liberated and floats as an oily layer on the surface of the liquid, and the aqueous layer responds to the reactions for zinc, page 690.

Tests for Purity—The salt is neutral to moistened litmus paper.

Boil 1 Gm. of Zinc Stearate with 25 cc. of distilled water and 5 cc. of hydrochloric acid, filter while hot, and wash the filter with 25 cc. of hot distilled water. Render the filtrate alkaline with ammonia T.S., warm to 80° C., and add ammonium sulphide T.S. in excess. Filter, evaporate the filtrate to dryness, and ignite the residue. Dissolve this residue in 10 cc. of hot distilled water, filter, again evaporate, ignite, and weigh. Not more than 1 per cent of residue remains (*alkalies or alkali earths*).

The insoluble residue of fatty acids obtained in the preceding test when well washed and dried over sulphuric acid, melts at a temperature not below 56° C.

Assay—Boil about 1 Gm. of Zinc Stearate, accurately weighed, with 50 cc. of tenth-normal sulphuric acid for ten minutes, cool, and filter. Wash the filter and flask thoroughly with distilled water and titrate the excess of sulphuric acid with tenth-normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of tenth-normal sulphuric acid corresponds to 0.004069 Gm. of ZnO.

This assay is explained on page 1458.

N. F. Preparation—Unguentum Zinci Stearatis.

Uses—Zinc stearate is used in the official ointment of zinc stearate, and as a dusting powder in dermatologic practice, for its desiccating and protective effect. Poisoning has been reported in cases of infants in which the powder has been carelessly and freely applied so that inhalation of the substance has resulted. Its use as a "baby powder" is therefore being generally discontinued, and, when used, a form of container having a self-closing aperture has been adopted by most manufacturers.

ZINCI SULPHAS. U. S. Zinc Sulphate
[Zinc. Sulph.]

Zinc Sulphate contains not less than 55.86 per cent and not more than 58.63 per cent of $ZnSO_4$ (161.43), corresponding to not less than 99.5 per cent of the crystallized salt [$ZnSO_4.7H_2O = 287.54$].

Preparation—Zinc sulphate is made by acting on metallic zinc or zinc oxide, in excess, with diluted sulphuric acid, hydrogen being evolved. The resulting solution is freed from the contamination of iron by first passing chlorine into it, when ferric chloride is produced. Upon the addition of zinc carbonate, decomposition takes place, ferric hydroxide separates as an insoluble precipitate, which is removed by filtration, and a small quantity of zinc chloride is formed, which, being very soluble, remains in the mother liquor after the crystallization of the sulphate.

$$\underset{\text{zinc}}{2Zn} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{2H_2SO_4} = \underset{\substack{\text{zinc}\\\text{sulphate}}}{2ZnSO_4} + \underset{\text{hydrogen}}{4H}$$

The salt may also be made by the action of sulphuric acid on zinc oxide according to the equation:

$$\underset{\substack{\text{zinc}\\\text{oxide}}}{ZnO} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{H_2SO_4} = \underset{\substack{\text{zinc}\\\text{sulphate}}}{ZnSO_4} + \underset{\text{water}}{H_2O}$$

Zinc sulphate is also prepared by roasting zinc sulphide in a limited supply of oxygen and extracting the sulphate with water.

Description and Physical Properties—Colorless, transparent, rhombic crystals, or a granular, crystalline powder, without odor, and having an astringent, metallic taste. It is efflorescent in dry air.

One Gm. of Zinc Sulphate is soluble in 0.6 cc. of water and in 2.5 cc. of glycerin, at 25° C. It is insoluble in alcohol.

When rapidly heated, Zinc Sulphate melts. When strongly ignited, it is partly decomposed, losing both water and sulphuric acid.

Its aqueous solution (1 in 10) is acid to litmus paper.

Tests for Identity—An aqueous solution of the salt responds to the reactions for zinc, page 690, and for sulphates, page 581.

Tests for Purity—A 10 cc. portion of an aqueous solution of Zinc Sulphate (1 in 50), acidulated with 1 cc. of diluted hydrochloric acid, meets the requirements of the test for *heavy metals*, page 1519.

An aqueous solution of the salt meets the requirements of the test for *arsenic*, page 1512.

An aqueous solution of Zinc Sulphate (1 in 20) is not colored pink by methyl orange T.S. (*free acid*).

One Gm. of Zinc Sulphate shows no more *chloride* than corresponds to 0.3 cc. of fiftieth-normal hydrochloric acid, page 1520.

Dissolve 1 Gm. of Zinc Sulphate in 50 cc. of distilled water, precipitate the zinc completely by means of ammonium sulphide T.S., filter, evaporate the filtrate to dryness, and ignite: the weight of the residue does not exceed 0.5 per cent (*alkalies or alkali earths*).

Assay—Proceed as directed under *Zinci Acetas*, using 1 Gm. of Zinc Sulphate. The weight of zinc oxide obtained, multiplied by 1.984, indicates its equivalent in $ZnSO_4$. Each Gm. of Zinc Sulphate corresponds to not less than 0.2815 Gm. and not more than 0.2955 Gm. of ZnO.

This assay is explained on page 1479.

Zinc Sulphate may also be assayed by the electrolytic method, page 1515.

Preserve in well-closed containers.

N. F. Preparations—Lotio Alba; Mistura Adstringens; Pulvis Antisepticus.

Uses—Zinc sulphate is the most important of the zinc salts. It is used medicinally as a prompt and certain emetic in doses of ten to thirty grains (0.6 to 2 Gm.); as a tonic and astringent, one to two grains (0.065 to 0.13 Gm.). It is also used locally for its astringent action.

Average dose—15 grains (1 Gm.).

ZINCI PHENOLSULPHONAS. N. F. Zinc Phenolsulphonate

(U. S. P. IX)

[**Zinc. Phenolsulph.**—ZINC SULPHOCARBOLATE]

Zinc Phenolsulphonate contains not less than 73.7 per cent and not more than 77.4 per cent of anhydrous zinc phenolsulphonate, corresponding to not less than 99.5 per cent of the crystallized salt $(C_6H_5O.SO_3)_2Zn.8_2O = 555.76$).

Preparation—This salt is made by mixing solutions of barium phenolsulphonate and zinc sulphate; barium sulphate is precipitated, the solution is evaporated, and the crystals which separate are washed and dried. The reaction is explained by the following equation:

$$\underset{\text{barium phenolsulphonate}}{Ba(C_6H_4OHSO_3)_2} + \underset{\text{zinc sulphate}}{ZnSO_4} = \underset{\text{zinc phenolsulphonate}}{Zn(C_6H_4OHSO_3)_2} + \underset{\text{barium sulphate}}{BaSO_4}$$

Description and Physical Properties—Zinc Phenolsulphonate occurs as colorless, transparent, rhombic prisms or tabular crystals, or in granular form; odorless, and having an astringent, metallic taste. When exposed to the air the salt effloresces, and upon exposure to light, and air may become slightly pink.

One Gm. of Zinc Phenolsulphonate dissolves in 1.6 cc. of water, and in 1.8 cc. of alcohol at 25° C.; also in 0.4 cc. of boiling water.

Tests for Identity—Its aqueous solution (1 in 10) is acid to litmus.

When heated to 125° C., the salt loses all of its water of crystallization. At a higher temperature, it chars, emitting inflammable vapors having the odor of phenol, and finally leaves an incombustible residue.

An aqueous solution of the salt (1 in 20) yields a white, gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S.

Ammonium carbonate T.S., when added in small portions to an aqueous solution of the salt (1 in 20) produces a white precipitate which redissolves completely upon the addition of an excess of the reagent.

A dilute solution of the salt (1 in 100) is colored pale violet by ferric chloride T.S.

Tests for Purity—The addition of a few drops of barium chloride T.S. to 10 cc. of an aqueous solution of the salt (1 in 20), previously acidulated with three drops of hydrochloric acid, produces not more than a slight turbidity (*sulphate*).

Ten cc. of an aqueous solution of the salt (1 in 50) to which 1 cc. of diluted hydrochloric acid has been added, does not respond to the test for heavy metals (see page 1519).

An aqueous solution of the salt meets the requirements of the test for arsenic (see page 1512).

Assay—Dissolve about 1 Gm. of Zinc Phenolsulphonate, accurately weighed, in 100 cc. of distilled water, render the solution slightly alkaline with ammonia water and warm it to 80° C. Completely precipitate the zinc as zinc sulphide by the addition of ammonium sulphide T.S. and warm the liquid on a water bath until the precipitate settles. Collect the precipitate on a filter, wash it with distilled water containing a few drops of ammonium sulphide T.S., then dissolve it in hot dilute nitric acid (1 in 3), evaporate the solution in a tared porcelain or platinum dish, ignite the residue and weigh it as zinc oxide. The amount of zinc oxide obtained multiplied by 5.059 indicates its equivalent in $Zn(C_6H_5SO_4)_2$.

This assay is explained on page 1479.

Zinc Phenolsulphonate may also be assayed by the electrolytic method (see U. S. P. X).

Preserve it in small, well-closed containers.

N. F. Preparation—Liquor Iodi et Zinci Phenolsulphonatis.

Uses—Zinc phenolsulphonate is used as an antiseptic astringent and stimulant. When used internally, it may be given in doses of two grains (0.13 Gm.).

CALAMINA PRÆPARATA. N. F. Prepared Calamine

[Calamin. Præp.—Lapis Calaminaris]

Prepared Calamine is Zinc Oxide containing a small amount of ferric oxide. It contains, after ignition, not less than 98 per cent ZnO (81.37).

Preparation—The native zinc oxide is calcined in covered earthen crucibles, then powdered and freed from gritty particles by elutriation. The pinkish color is due to the presence of iron. The name *calamine* is applied more frequently by mineralogists to a native form of zinc silicate, which being insoluble is not suitable for use in this preparation. The true *calamine*, which is the impure oxide, is easily distinguished from the silicate by adding diluted hydrochloric acid which almost completely dissolves the former, but has no effect upon the latter. *Artificial calamine* has been found on the market prepared by mixing zinc carbonate, zinc oxide, and ferric oxide, or by coloring talc or other insoluble substances with ferric hydroxide.

Description and Physical Properties—Prepared Calamine is a pink powder passing through a No. 100 sieve.

It is insoluble in water but dissolves in mineral acids, leaving a small amount of insoluble residue.

Tests for Identity and Purity—A filtered solution of Prepared Calamine in diluted hydrochloric acid yields the reactions of zinc.

Digest 1 Gm. of Prepared Calamine with 20 cc. of warm water, filter and add 2 drops of phenolphthalein T.S. If a red color is produced, not more than 0.2 cc. of tenth-normal sulphuric acid is required to discharge it (*alkaline substances*).

0.2 Gm. of Prepared Calamine dissolved in 5 cc. of diluted sulphuric acid meets the requirements of the test for arsenic (see page 1512).

Dissolve 1 Gm. of Prepared Calamine in 25 cc. of diluted hydrochloric acid, filter, and add to the filtrate ammonia water until the precipitate first formed is redissolved, then add 5 cc. more ammonia water. To 10 cc. of this solution add 2 cc. of ammonium oxalate T.S. Not more than a slight turbidity is produced (*calcium*). To another 10 cc. portion add 2 cc. of sodium phosphate T.S. Not more than a slight turbidity is produced (*calcium* or *magnesium*.)

To 1 Gm. of Prepared Calamine add 15 cc. of water, stir well, then add 3 cc. of glacial acetic acid, warm on the water bath until dissolved and filter. On adding five drops of potassium chromate T.S. to the filtrate no turbidity is produced (*lead*).

Assay—Ignite about 1.5 Gm. of Prepared Calamine, cool, weigh accurately and dissolve it by warming with 50 cc. of normal sulphuric acid. Filter, wash the residue and filter with hot distilled water until the washings are no longer acid to litmus paper, then titrate the combined cooled filtrate and washings with normal sodium hydroxide, using methyl orange as indicator. Each cc. of normal sulphuric acid corresponds to 0.04069 Gm. of ZnO.

This assay is explained on page 1458.

N. F. Preparations—Linimentum Calaminæ; Lotio Calaminæ; Lotio Calaminæ Composita; Unguentum Calaminæ.

Uses—Its uses are similar to those for zinc oxide, being employed chiefly in protective ointments and lotions. It is often prescribed by dermatologists to give color to lotions or ointments.

Unofficial Salts of Zinc

Zinci Bromidum, $ZnBr_2$ Zinc Bromide	A white, hygroscopic crystalline powder; soluble in water. It is used in medicine as an antiepileptic. The dose is 1 to 2 grains (0.06 to 0.13 Gm.)
Zinci Carbonas Praecipitatus, U. S. P. IX Precipitated Zinc Carbonate	An impalpable white powder; insoluble in water but dissolved by dilute acids, with effervescence. It is used in skin diseases, principally in ointments, and is often used to replace the impure carbonate, termed *calamine*, which is now official in the N. F. (see page 697), but as an important quality of the latter is its pink color, the substitution is not usually satisfactory. It is sometimes dusted upon inflamed surfaces as an astringent and absorbent
Zinci Cyanidum, $Zn(CN)_2$ Zinc Cyanide	A poisonous, white powder; insoluble in water. It is used in medicine as an alterative, antiseptic, and anthelmintic. The dose is from $\frac{1}{10}$ to 1 grain (0.006 to 0.06 Gm.)
Zinci Dioxidum, ZnO_2 Zinc Dioxide, Zinc Peroxide	A white powder; insoluble in water and decomposed by acids. It is used as a bactericide and in medicine as a dressing for wounds
Zinci et Potassii Cyanidum, K_2ZnCN_4 Zinc and Potassium Cyanide	White crystals; soluble in water and having the medicinal properties of hydrocyanic acid. The dose is $\frac{1}{10}$ to 1 grain (0.006 to 0.06 Gm.)
Zinci Ferrocyanidum, $Zn_2FeCN_6.2H_2O$ Zinc Ferrocyanide	A white powder; insoluble in water. It is used as an alterative and antiseptic. The dose is ½ to 2 grains (0.03 to 0.13 Gm.)
Zinci Iodidum, ZnI_2 Zinc Iodide	A hygroscopic, white, crystalline powder; very soluble in water. It is used in medicine as an alterative and antiseptic. The dose is 1 to 2 grains (0.06 to 0.13 Gm.)
Zinci Lactas, $Zn(C_3H_5O_3)_2.3H_2O$ Zinc Lactate	White crystals, slightly soluble in water. It is used as an antiepileptic. The dose is ½ to 1 grain (0.03 to 0.06 Gm.)

Unofficial Salts of Zinc—*Continued*

Zinci Permanganas, $Zn(MnO_4)_2.6H_2O$ Zinc Permanganate N. N. R.	Violet brown, or almost black, hygroscopic crystals; very soluble in water. It is used in medicine as an antiseptic and astringent, and is used in urethritis as an injection or douche in 1 to 4000 solution. This salt is more fully described in the New and Nonofficial Remedies of 1925
Zinci Phosphidum, Zn_3P_2 Zinc Phosphide	A dark gray, gritty powder having a faint odor of phosphorus. It is insoluble in water but is dissolved by acids with the evolution of hydrogen phosphide. It is used as a stimulant to the nervous system. The dose is $\frac{1}{60}$ to $\frac{1}{2}$ grain (0.001 to 0.03 Gm.)
Zinci Salicylas, $Zn(C_7H_5O_3)_2.3H_2O$ Zinc Salicylate	White crystalline needles, soluble in water. It is used externally as a dusting powder and internally in place of zinc oxide. The dose is $\frac{1}{2}$ to 1 grain (0.03 to 0.06 Gm.)
Zinci Sulphanilas, N. N. R. $Zn(C_6H_4(NH_2)SO_3)_2.H_2O$ Zinc Sulphanilate, Soloid Nizin	Water-soluble tablets used in aqueous solution as an astringent and antiseptic. These tablets are prepared by Burroughs Wellcome and Company, and are described in the New and Nonofficial Remedies of 1925
Zinci Sulphidum, ZnS Zinc Sulphide	A yellowish-white powder, insoluble in water. It is used as a pigment in paints; with zinc oxide it constitutes *mineral white* and with barium sulphate, *lithopone*
Zinci Valeras, $Zn(C_5H_9O_2)_2.2H_2O$, U. S. P. IX Zinc Valerate	White pearly scales or a white powder, having the odor of valeric acid. It is readily soluble in water but, on exposure to air, it loses valeric acid and becomes less soluble. Zinc valerate is used in nervous diseases. The dose is from 1 to 3 grains (0.06 to 0.2 Gm.)
Oleatum Zinci Oleate of Zinc	A white, greasy, granular powder; soluble in alcohol and in ether, but insoluble in water. It is chiefly used externally as an antiseptic and astringent

Aluminum, Al; 27.0

Aluminum is from the Latin word "alumen", signifying alum. The metal is found largely in combination with silicic acid, in the rocks and clays forming a great portion of the earth's surface. Some of the precious stones and valuable minerals are compounds of aluminum; the ruby and sapphire, corundum, and emery, are crystallized forms of aluminum oxide. *Kaolin*, *clay*, and *fuller's earth* are well-known forms of native materials chiefly composed of aluminum silicates. Vast quantities of aluminum are chemically combined in the double silicates of aluminum and an alkali metal in the form of *feldspar* and *mica*. Aluminum is of a silver-white color. The metal, owing to improvements in its smelting, is much cheaper than it was formerly, and is extensively used in making ornamental and useful articles and, when suitably alloyed, forms light metals of great strength which are being used in engines and other large machines. Owing to its very low specific gravity (2.64 to 2.70), it is used for grain weights, because they are much larger, and thus more easily handled, than those made from brass (see page 50). Aluminum forms but one class of compounds used in medicine; it is trivalent. The oxides and sulphates unite with those of the alkali metals and form doublesalts, called alums.

Tests for Salts of Aluminum

Solutions of aluminum salts yield with ammonia T.S. a white precipitate which is insoluble in a moderate excess of ammonium hydroxide. Sodium hydroxide T.S. or sodium sulphide T.S. produces a similar precipitate which dissolves in an excess of either of these reagents.

ALUMEN. U. S. Alum

[Alum.]

Alum contains not less than 99.5 per cent of $AlNH_4(SO_4)_2.12H_2O$ (453.35) or $AlK(SO_4)_2.12H_2O$ (474.41). The label of the container must indicate whether the salt is Ammonium Alum or Potassium Alum.

Preparation—This valuable salt is made from alum clay, which is chiefly aluminum silicate, but contains iron pyrites, which on calcination furnishes the

sulphuric acid to combine with the alumina of the clay to form aluminum sulphate. It is also prepared on a large scale from aluminum hydroxide, a by-product in the cryolite process for making sodium carbonate. Potassium or ammonium sulphate or chloride is then added, when the double salt $AlK(SO_4)_2$ or $AlNH_4(SO_4)_2$ is produced. Both salts crystallize with twelve molecules of water. Ammonium alum, $AlNH_4(SO_4)_2$, is generally found in the market, because of its greater cheapness. Soda alum has been prepared, but cannot be crystallized in stable form. In the anhydrous form soda alum is the acidic element in the so-called "alum baking powders". It is known to the trade as "S. A. S." (sodium aluminum sulphate).

Description and Physical Properties—Large, colorless crystals, crystalline fragments, or a white powder. Alum is odorless, and has a sweetish, strongly astringent taste.

One Gm. of Ammonium Alum is soluble in 5.2 cc. of water at 25° C. and in 0.3 cc. of boiling water.

One Gm. of Potassium Alum is soluble in 7.2 cc. of water at 25° C. and in 0.3 cc. of boiling water.

Alum is insoluble in alcohol but is freely soluble in glycerin.

When heated, Alum fuses, and at about 200° C. loses all of its water of crystallization. When strongly heated, it loses sulphuric anhydride, becoming incompletely soluble in water.

Tests for Identity—Sodium hydroxide T.S. added to an aqueous solution of Ammonium Alum (1 in 20) at first causes a precipitate, which completely dissolves in an excess of the reagent, ammonia being evolved.

Potassium Alum imparts a violet color to a non-luminous flame.

The addition of 10 cc. of sodium bitartrate T.S. to 5 cc. of a saturated aqueous solution of Potassium Alum produces within thirty minutes a white, crystalline precipitate.

Sodium hydroxide T.S. added to an aqueous solution of Potassium Alum (1 in 20) at first causes a precipitate, which completely dissolves in an excess of the reagent, but no ammonia is evolved.

Unless otherwise indicated Ammonium Alum and Potassium Alum conform to the following tests:

An aqueous solution of Alum (1 in 20) is acid to litmus paper.

An aqueous solution of Alum (1 in 20) responds to the reactions for aluminum, page 698, and for sulphates, page 581.

Tests for Purity—An aqueous solution of Alum meets the requirements of the test for *heavy metals*, page 1519.

An aqueous solution of Alum meets the requirements of the test for *arsenic*, page 1512.

Add 5 drops of potassium ferrocyanide T.S. to 20 cc. of an aqueous solution of Alum (1 in 150): no blue color is produced immediately (*iron*).

Completely precipitate the aluminum from a boiling solution of 1 Gm. of Ammonium Alum in 100 cc. of distilled water by the addition of a slight excess of ammonia water, and filter: not more than 0.5 per cent of residue remains on evaporating the filtrate to dryness and igniting (*alkali and earths*).

Assay—Dissolve about 1 Gm. of Alum, accurately weighed, and about 1 Gm. of ammonium chloride in 250 cc. of distilled water. Heat the solution to boiling, and add a slight excess of ammonia T.S. to precipitate aluminum hydroxide. Collect the precipitate on a filter, wash thoroughly with hot distilled water, dry, ignite strongly, and weigh. The weight of the aluminum oxide so obtained, multiplied by 8.889, indicates its equivalent in $AlNH_4(SO_4)_2.12H_2O$ and when multiplied by 9.302 indicates its equivalent in $AlK(SO_4)_2.12H_2O$. Each Gm. of aluminum oxide corresponds to 8.874 Gm. of $AlNH_4(SO_4)_2.12H_2O$ and to 9.286 Gm. of $AlK(SO_4)_2.12H_2O$.

This assay is explained on page 1477.

U. S. P. Preparation—Alumen Exsiccatum.

N. F. Preparation—Liquor Cocci.

History—Alum was a mystery to the ancient chemists and pharmacists. They were acquainted with its properties but could not fathom its composition. It was called alumen by Pliny and *stypteria* by Dioscorides. It was extensively used in early times as a mordant in dyeing.

Uses—Alum is a powerful astringent because of its precipitation of albumin. It is slightly antiseptic. When powdered, it is used as an emetic in croup, in doses of a teaspoonful. It is sometimes used as a local styptic, and is frequently employed in making astringent lotions and injections. The dose as an astringent is from five to twenty grains (0.32 to 1.3 Gm.).

ALUMEN EXSICCATUM. U. S. Exsiccated Alum

[Alumn. Exsic.—Alumen Ustum, Dried Alum, Burnt Alum]

Exsiccated Alum, when recently dried to constant weight at 200° C., contains not less than 96.5 per cent of $AlNH_4(SO_4)_2$ (237.16) or of $AlK(SO_4)_2$ (258.22). The label of the container must indicate whether it is made from Ammonium Alum or Potassium Alum.

Alum, in small pieces	**100 Gm.**	20 oz. av.
To make about	**55 Gm.**	11 oz. av.

Place a thin layer of alum in a tared, shallow, porcelain dish, and heat it cautiously on a sand bath until liquefied. Continue the application of heat at a temperature not exceeding 200° C., and stir constantly until aqueous vapors cease to evolve and a dry, white, porous mass is obtained. When cold, reduce the product to a fine powder.

This preparation represents alum nearly deprived of its water of crystallization; the latter exists in alum in the large proportion of about 45 per cent, thus constituting almost half of its weight. Great care must be observed in the regulation of the heat during the exsiccation, as temperatures above 200° C. produce insoluble compounds of alum, chiefly aluminum oxysulphate.

Description and Physical Properties—A white, odorless powder. It has a sweetish, astringent taste, and absorbs moisture on exposure to air.

One Gm. of Exsiccated Alum is very slowly and usually incompletely soluble in about 20 cc. of water at 25° C. One Gm. is soluble in about 1.5 cc. of boiling water. It is insoluble in alcohol.

Tests for Identity—Exsiccated Alum responds to the reactions, respectively, for Ammonium Alum or Potassium Alum described under *Alumen*.

Tests for Purity—Add 2 Gm. of Exsiccated Alum to 40 cc. of distilled water, and allow it to stand with occasional agitation for twenty-four hours. Collect the insoluble residue on previously dried, counterbalanced filter papers, or a Gooch crucible, wash with 50 cc. of distilled water, and finally dry to constant weight at 100° C.: the residue weighs not more than 0.05 Gm.

Dry about 1 Gm. of Exsiccated Alum to constant weight at 200° C. in an air bath: the loss does not exceed 10 per cent.

An aqueous solution of Exsiccated Alum meets the requirements for *arsenic*, *heavy metals*, *iron*, and Exsiccated Ammonium Alum meets the test for limit of *alkali and earths*, under *Alumen*, allowance being made for the difference in strength.

Assay—Dry about 0.5 Gm. of Exsiccated Alum to constant weight at 200° C., weigh accurately, and dissolve in 100 cc. of distilled water. Filter, if necessary, thoroughly wash the insoluble residue with distilled water, dilute the filtrate and washings to about 250 cc. with distilled water, and add 1 Gm. of ammonium chloride. Proceed with the assay as directed under *Alumen*, beginning with the words "Heat the solution", second line of the assay. The weight of the aluminum oxide so obtained, multiplied by 4.650, indicates its equivalent in $AlNH_4(SO_4)_2$, and multiplied by 5.063 indicates its equivalent in $AlK(SO_4)_2$. Each Gm. of aluminum oxide corresponds to 4.643 Gm. of $AlNH_4(SO_4)_2$ and to 5.055 Gm. of $AlK(SO_4)_2$.

This assay is explained on page 1478.

Preserve in well-closed containers and do not dispense if it contains more than 10 per cent of moisture.,

Uses—It is used as an escharotic and is more powerful than alum not only because it is more concentrated but it also absorbs water from the tissues on account of being very hygroscopic.

ALUMINI CHLORIDUM. N. F. Aluminum Chloride

[Alum. Chlor.]

Aluminum chloride contains $AlCl_3.6H_2O$ (241.58) corresponding to not less than 20.5 per cent of aluminum oxide (Al_2O_3).

Preparation—Aluminum chloride may be prepared by heating aluminum in a current of chlorine, or by dissolving freshly precipitated aluminum hydroxide in hydrochloric acid and evaporating off the water, as follows:

$$\underset{\text{aluminum hydroxide}}{Al(OH)_3} + \underset{\text{hydrochloric acid}}{3HCl} = \underset{\text{aluminum chloride}}{AlCl_3} + \underset{\text{water}}{3H_2O}$$

Description and Physical Properties—Aluminum Chloride occurs as a white, or yellowish-white deliquescent, crystalline powder; nearly odorless; taste sweetish and very astringent.

One gram dissolves in about 0.5 cc. of water and in about 4 cc. of alcohol at 25° C., also soluble in glycerin.

Tests for Identity—An aqueous solution of the salt (1 in 10) is clear, and is acid to litmus. Separate portions of an aqueous solution of the salt (1 in 10) yield with silver nitrate T.S. a white curdy precipitate insoluble in nitric acid, with ammonia water a white gelatinous precipitate almost insoluble in an excess of ammonia water, and with sodium hydroxide T.S. a white gelatinous precipitate completely soluble in an excess of the reagent.

Tests for Purity—Ten cc. of an aqueous solution of the salt (1 in 100) after the addition of 0.2 cc. of barium chloride T.S., does not become cloudy within one minute (*sulphate*).

The addition of 0.3 cc. of potassium ferrocyanide T.S. to 20 cc. of an aqueous solution of the salt (1 in 50) does not produce a blue coloration within one minute (*iron*).

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

An aqueous solution of the salt meets the requirements of the test for arsenic (see page 1512).

Assay—Dissolve about 0.5 Gm. of the salt, previously dried over sulphuric acid and accurately weighed, in 100 cc. of distilled water, add 1 Gm. of ammonium chloride and then precipitate the aluminum hydroxide by the addition of a slight excess of ammonia water to the boiling solution. Collect the precipitate on a filter, wash it with distilled water, dry, ignite thoroughly and weigh. The weight of the aluminum oxide so obtained is not less than 20.5 per cent of the weight of the Aluminum Chloride taken for the assay.

This assay is explained on page 1478.

Preserve it in well-closed containers.

N. F. Preparation—Liquor Hydrastinæ Compositus.

Uses—Used in solution or pills in doses of two to five grains (0.13 to 0.32 Gm.). Because of the deliquescence of the salt, if made into pills they should be massed with Canada turpentine and powdered althæa. It is an astringent and antiseptic. The solution sold as *chloralum* is said to be a 20 per cent aqueous solution of aluminum chloride. Many proprietary preparations, sold as *perspiration preventatives* or as *deodorants*, are solutions of aluminum chloride, some being as high as 30 per cent in strength.

ALUMINI SULPHAS. N. F. Aluminum Sulphate

[Alum. Sulph.]

Aluminum sulphate contains not less than 99.5 per cent of $Al_2(SO_4)_3.18H_2O$ (666.47).

Preparation—Aluminum sulphate may be prepared from alum as follows: Take of alum and sodium carbonate, each 4 oz. troy; sulphuric acid, 1 oz. troy, 150 gr.; distilled water, a sufficient quantity. Dissolve the salts separately, each in 6 fluidounces of boiling water, and pour the solution of the alum gradually into that of the sodium carbonate; then digest with a gentle heat until the evolution of carbon dioxide ceases. Collect upon a filter the precipitate formed, and wash it with water, until the washings are no longer affected by barium chloride T.S. Next, with the aid of heat, dissolve the precipitate in the sulphuric acid, previously diluted with half a pint of water, and, having filtered the solution, evaporate it until a pellicle begins to form. Then remove it to a water bath, and continue the evaporation, with constant stirring, until a dry salt remains. Lastly, preserve this in a well-stoppered bottle.

Another method may be used: freshly precipitated hydroxide may be dissolved in diluted sulphuric acid, the solution evaporated, and the salt granulated.

Description and Physical Properties—Aluminum Sulphate occurs as a white, crystalline powder, shining plates, or crystalline fragments; without odor, having a sweetish and afterwards an astringent taste; permanent in the air.

One Gm. dissolves in 1 cc. of water at 25° C.; it is more soluble in boiling water, but insoluble in alcohol.

Tests for Identity—When gradually heated to about 200° C., it loses its water of crystallization (about 45.7 per cent of its weight).

An aqueous solution of the salt (1 in 20) is acid to litmus.

Separate portions of an aqueous solution of the salt (1 in 20) yield with barium chloride T.S. a white precipitate insoluble in hydrochloric acid, and with sodium hydroxide T.S. a white gelatinous precipitate which is soluble in an excess of the alkali, but which is again separated on the addition of a sufficient amount of ammonium chloride T.S.

Tests for Purity—Gently heat 1 Gm. of Aluminum Sulphate with 10 cc. of sodium hydroxide T.S.; the liquid does not evolve the odor of ammonia.

A filtered aqueous solution of the salt (1 in 10) does not become more than faintly opalescent within five minutes after the addition of an equal volume of tenth-normal sodium thiosulphate (*free acid*).

The addition of 5 drops of potassium ferrocyanide T.S. to 20 cc. of an aqueous solution of the salt (1 in 150) does not produce at once a blue coloration (*iron*).

An aqueous solution of the salt does not respond to the test for heavy metals (see page 1519).

An aqueous solution of the salt meets the requirements of the test for arsenic (see page 1512).

Assay—Dissolve about 0.5 Gm. of Aluminum Sulphate, accurately weighed, in 100 cc. of distilled water, add 1 Gm. of ammonium chloride and then precipitate the aluminum hydroxide by the addition of a slight excess of ammonia water to the boiling solution. Collect the precipitate on a filter, wash it with distilled water, dry, ignite thoroughly and weigh. The weight of the aluminum oxide so obtained is not less than 15.23 per cent of the weight of the Aluminum Sulphate taken for the assay, corresponding to not less than 99.5 per cent of $Al_2(SO_4)_3.18H_2O$.

This assay is explained on page 1478.

N. F. Preparations—Liquor Alumini Acetatis, Liquor Alumini Subacetatis.

Uses—Aluminum sulphate is a powerful astringent acting much like alum.

PUMEX. N. F. Pumice

A substance of volcanic origin, consisting chiefly of complex silicates of aluminum, potassium, and sodium.

Description and Physical Properties—Pumice occurs as very light, hard, rough, porous gray masses, or as a gritty, gray-colored powder. It is permanent in the air, odorless and tasteless. The dry masses usually float on water.

Tests for Purity—Boil 10 Gm. of Pumice with 50 cc. of distilled water for one-half hour, adding distilled water from time to time to maintain approximately the original volume and then filter; the filtrate is neutral to litmus and one-half of this filtrate, when evaporated and the residue dried to constant weight at 110° C., yields not more than 0.01 Gm. of residue (*soluble substances*). The remaining half of the filtrate, after slightly acidulating with hydrochloric acid, does not yield a blue color with potassium ferrocyanide T.S. (*iron*).

Boil 1 Gm. of Pumice with 25 cc. of diluted hydrochloric acid for one-half hour, adding distilled water from time to time to maintain approximately the original volume, and then filter the liquid; the filtrate yields upon evaporating to dryness, igniting and quickly weighing, not more than 0.05 Gm. of residue.

N. F. Preparations—Elixir Eriodictyi Aromaticum; Mistura Chloralis et Potassii Bromidi Composita; Tinctura Guaiaci Composita.

Uses—Pumice is used as a filtering and distributing medium in several N. F. Preparations. Because of its grittiness, powdered pumice is also used in certain soaps and cleaning powders.

LIQUOR ALUMINI ACETATIS. N. F. Solution of Aluminum Acetate

[Liq. Alumin. Acet.—Liquor Burowii, Burow's Solution]

An aqueous solution containing not less than 4.5 Gm. and not more than 5.5 Gm. of neutral aluminum acetate ($Al(C_2H_3O_2)_3 = 204.10$) in each 100 cc.

	Metric	Alternative
Lead Acetate	**150 Gm.**	5 oz. av. 3 gr.
Aluminum Sulphate	**85 Gm.**	2 oz. av. 366 gr.
Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve each salt separately in 450 cc. [14 fl. oz. 192 min.] of water and mix the cold solutions by pouring the lead acetate solution in a thin stream, with constant stirring, into the aluminum sulphate solution. Set the mixture aside in a cold place (about 10° C.) for twenty-four hours, stirring it occasionally, and then siphon off the clear liquid. Transfer the magma to a strainer of fine texture, press it and add sufficient water through the magma to make the filtered mixed liquids measure 1000 cc. [2 pints].

Dispense only the clear solution.

Note—This Solution should not be confused with Liquor Alumini Acetatis N. F. III, which is a stronger preparation, now recognized under the name of Liquor Alumini Subacetatis.

Solution of Aluminum Acetate is a clear, colorless liquid with a faint acetic odor, a sweetish astringent taste, and an acid reaction. In addition to aluminum acetate it contains a small but variable proportion of dissolved lead sulphate.

Warm 5 cc. of the Solution with 1 cc. of sulphuric acid and 1 cc. of alcohol; ethyl acetate is produced, which is recognized by its odor.

To 5 cc. of Solution of Aluminum Acetate, diluted with 25 cc. of water, add 0.5 Gm. of ammonium chloride and a slight excess of ammonia water: a gelatinous precipitate of aluminum hydroxide is produced.

To 5 cc. of the Solution add 5 cc. of hydrogen sulphide T.S.: a dark coloration but no precipitate is produced.

Assay—Dissolve 1 Gm. of ammonium chloride in 5 cc. of the Solution, accurately measured, and add enough distilled water to measure 250 cc. Precipitate the aluminum by the addition of a

slight excess of ammonia water to the boiling solution, collect the precipitate on a filter, wash it thoroughly with hot distilled water, ignite it strongly, and weigh the residue. The weight of the residue multiplied by 3.994 represents its equivalent in $Al(C_2H_3O_2)_3$. Each cc. of Solution of Aluminum Acetate corresponds to not less than 0.01126 Gm. nor more than 0.01376 Gm. of aluminum oxide (Al_2O_3).

This assay is explained on page 1478.

Uses—This solution derives its synonym from the fact that Dr. August Burow, of the University of Köenigsberg in 1857, prescribed a similar solution. In the original solution, alum replaced aluminum sulphate but the latter is preferable, being more certain to precipitate all of the lead. It is usually diluted with water, is used as a non-toxic antiseptic dressing, also as an astringent and antiseptic mouth wash and gargle.

LIQUOR ALUMINI SUBACETATIS. N. F. Solution of Aluminum Subacetate

[Liq. Alumin. Subacet.]

An aqueous solution, containing not less than 7.5 Gm. and not more than 8.5 Gm. of basic aluminum acetate ($Al(C_2H_3O_2)_2OH = 162.08$) in each 100 cc.

	Metric	Alternative
Aluminum Sulphate	**160 Gm.**	5 oz. av. 149 gr.
Acetic Acid	**160 cc.**	5 fl. oz. 58 min.
Precipitated Calcium Carbonate	**70 Gm.**	2 oz. av. 147 gr.
Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve the aluminum sulphate in 600 cc. [19 fl. oz.] of water, filter the solution, and gradually add the precipitated calcium carbonate, in several portions, with constant stirring. Then slowly add the acetic acid and set the mixture aside for several days, stirring occasionally. Siphon off the clear liquid, transfer the magma to a strainer, press it and pass sufficient water through the magma to make the filtered, mixed liquids measure 1000 cc. [2 pints].

Solution of Aluminum Subacetate is a clear, colorless or faintly yellow liquid, having an acetous odor. It gradually becomes turbid on continued standing, due to separation of a more basic salt. It is acid to litmus paper.

Ammonia water produces a white gelatinous precipitate, soluble in an excess of hydrochloric acid.

Barium chloride T.S. produces a white precipitate, insoluble in an excess of hydrochloric acid.

Assay—Add 5 cc. of the Solution, accurately measured, 1 Gm. of ammonium chloride and enough distilled water to measure 250 cc. Precipitate the aluminum by the addition of a slight excess of ammonia water to the boiling solution. Collect the precipitate on a filter, wash it thoroughly with hot distilled water, ignite it strongly and weigh the residue. The weight of the residue multiplied by 3.172 represents its equivalent in $Al(C_2H_3O_2)_2OH$. Each cc. of Solution of Aluminum Subacetate corresponds to not less than 0.02363 Gm. and not more than 0.02836 Gm. of aluminum oxide (Al_2O_3).

This assay is explained on page 1478.

Uses—It is used as an antiseptic and astringent wash.

Unofficial Salts of Aluminum

Alumini Acetas, $Al(C_2H_3O_2)_3$ Aluminum Acetate	A white, crystalline powder; soluble in water. It is chiefly used as a mordant, also as a disinfectant by embalmers. It is also used, internally, for diarrhea and dysentery. Dose, 5 to 10 grains (0.3 to 0.6 Gm.)
Alumini Bromidum, $AlBr_3$ Aluminum Bromide	White to yellowish deliquescent crystals; soluble in water. It is chiefly used in making synthetic organic compounds
Alumini Hydroxidum, $Al(OH)_3$ U. S. P. IX Aluminum Hydroxide	A white, bulky, amorphous powder; insoluble in water. It is largely used as a mordant for dyeing, in the manufacture of colors and lakes, also as a filtering medium. In medicine it is used as a desiccant powder, and as an absorbent and antacid. The dose is from 2 to 5 grains (0.13 to 0.3 Gm.)
Alumini Iodidum, AlI_3 Aluminum Iodide	Brown crystalline pieces; readily soluble in water. It is used as an antiseptic and in organic synthesis
Alumini Naphtholsulphonas, $Al_2(C_{10}H_5OH(SO_3)_2)_3$ Aluminum Betanaphthol-Disulphonate, Alumnol	A fine white powder; soluble in water. It is used as a surgical antiseptic, generally in solution. Alumnol is more fully described in the New and Nonofficial Remedies of 1925
Alumini Nitras, $Al(NO_3)_3.9H_2O$ Aluminum Nitrate	Colorless, deliquescent crystals; very soluble in water. This salt is chiefly used in the textile and leather industries
Alumini Oxidum, Al_2O_3 Aluminum Oxide	This compound occurs native in the minerals, corundum, emery, ruby, and sapphire. Ordinarily it is a white bulky powder; insoluble in water. It is used in preparing metallic aluminum, as an abrasive and in the manufacture of refractory crucibles and tubes
Alumini Phosphas, $AlPO_4$ Aluminum Phosphate	A white, crystalline powder; insoluble in water. It is chiefly used in ceramics and as a cement in admixture with plaster of Paris and water glass

THORIUM AND ITS COMPOUNDS

Thorium is from the mineral *thoria* in which it is found and which, in turn, was named after the Scandinavian god, Thor. It belongs to the group of what are known as *rare earth elements* which include cerium, lanthanum, didymium, etc. The atomic weight of the element is 232.15. Its specific gravity is about eleven, and its melting point about 1700° C. It occurs in the minerals, *thorite, thorianite, orangite,* and *monazite.* Its oxide is one of the important constituents of incandescent gas mantles.

It is a radio-active element (see Radium, page 684), yielding a number of degradation products, the most important of which is *mesothorium.*

It forms two oxides, ThO_2 and Th_2O_7; a chloride, $ThCl_4$; and a nitrate, $Th(NO_3)_4$ which crystallizes in several hydrated forms.

The soluble thorium salts resemble alum in their irritant and astringent properties. Hypodermically they usually cause local sloughing, and intravenously produce death by coagulation of the blood. The double salts are practically nontoxic even intravenously and are excreted by the kidneys.

In consequence of their radio-activity the thorium salts have been recommended for local application in malignant growths, and the thorium emanation has been used in pulmonary diseases. The salts that have appeared upon the market are *thorium nitrate,* $Th(NO_3)_4 4H_2O$, in white, crystalline granules or lumps, very soluble in water or alcohol, and *thorium-sodium citrate* which is available in solution form in two strengths, the weaker containing the equivalent of 10 Gm. of thorium nitrate in 100 cc. of solution, and the stronger containing the equivalent of 15 Gm. of thorium nitrate in 100 cc. of solution. These solutions are used in the diagnosis of diseases of the renal pelvis and urinary bladder, as the double salt after absorption is opaque to the passage of the Roentgen rays. These solutions are called *thorium solution for cystography* and *thorium solution for pyelography,* respectively (See N. N. R. 1925).

Actinium is also a disintegration product of thorium.

Cerium, Ce; 140.25

Cerium is a metal occurring in *cerite, gadolinite, monazite,* etc.; it is of a chocolate-brown color in masses, and has been obtained by the electrolysis of the chloride; it takes fire more easily than magnesium; at ordinary temperatures it oxidizes in a moist atmosphere. Two oxides of cerium are known, Ce_2O_3, *cerous oxide,* and CeO_2, *ceric oxide.*

The commercial supplies are obtained as a by-product of the manufacture of the well-known incandescent gas mantles which consist of oxides of *thorium, lanthanum, didymium,* and *cerium.*

There are no salts of cerium official, although the oxalate is used and was official in the U. S. P. IX.

When cerium is scratched with a hard steel edge, it emits brilliant sparks and for this reason it is used in sparking or friction alloys for gas lighters, cigar lighters, etc.

History—Named from the minor planet Ceres which was discovered at about the same time.

Tests for Cerium Compounds

If sodium hypochlorite is added to a solution of a colorless cerous salt, a red precipitate separates; this dissolves in warm hydrochloric acid, and evolves chlorine.

Unofficial Salts of Cerium

Cerii Oxidum, CrO_2 Ceric Oxide	A pale yellow, heavy powder; insoluble in water. It is used in ceramics and is present in the incandescent gas mantles
Cerii Chloridum, $Ce_2Cl_6.14H_2O$ Cerium Chloride	Reddish-white crystals; very soluble in water. It is used in the preparation of other cerium compounds, as in incandescent lighting
Cerii Nitras, $Ce(NO_3)_3.6H_2O$ Cerium Nitrate	Reddish-white crystals; very soluble in water. It is used with thorium nitrate in the manufacture of incandescent gas mantles
Cerii Oxalas, U. S. P. IX Cerium Oxalate	A mixture of the oxalates of cerium, didymium, lanthanum and other associated elements. A fine, white, or slightly pink powder; insoluble in water. It is used in irritated states of the stomach, especially when there is nausea or vomiting. Its action is probably that of a mechanical protection. The dose is from 1 to 10 grains (0.06 to 0.6 Gm.)
Cerii Sulphas, $Ce(SO_4)_2.4H_2O$ Cerium Sulphate	Reddish-yellow crystals; soluble in water. It is used in photography and also in the determination of nitrous acid

Cadmium, Cd; 112.40

Cadmium is from the Greek word "kadmia", meaning calamine, an ore of zinc, with which it is associated. Although it enters into no official preparations, it is used to some extent in medicine, and hence merits a notice here. It is a white metal, resembling tin, but somewhat heavier and more tenacious. Like that metal, it crackles when bent. Its specific gravity is 8.6 and the metal melts at 320° C. (608° F.) and boils at 770° C. (1418° F.). It is little affected by the air, but when heated combines with an atom of oxygen, forming a reddish-brown or orange-colored oxide, CdO. It combines with chlorine, iodine, bromine, and sulphur.

Tests for Cadmium Salts

Neutral, alkaline, or moderately acid solutions of cadmium salts yield a yellow precipitate with hydrogen sulphide. This precipitate is insoluble in alkali hydroxides, in alkali sulphides, and in cold dilute acids, but it is soluble in cold, moderately dilute nitric acid, in hot dilute hydrochloric acid, or in hot moderately dilute sulphuric acid.

Cadmium sulphide differs from the sulphides of arsenic and antimony in that it is insoluble in solutions of the alkali sulphides.

Unofficial Salts of Cadmium

Cadmii Bromidum, $CdBr_2$ Cadmium Bromide	A yellowish, crystalline powder; soluble in water. It is mainly used in photography
Cadmii Chloridum, $CdCl_2$ Cadmium Chloride	Small, white crystals; soluble in water. It is used in photography, dyeing, and calico printing; also as a reagent and in the preparation of cadmium sulphide
Cadmii Iodidum, CdI_2 Cadmium Iodide	Colorless, flaky crystals; soluble in water. It is used in photography and externally as a resolvent and antiseptic, generally mixed with lard
Cadmii Oxidum, CdO Cadmium Oxide	This compound is closely related to zinc oxide, but has a dark brown color
Cadmii Sulphidum, CdS Cadmium Sulphide	A light-yellow powder; insoluble in water. It is used as a yellow paint pigment, in pyrotechnics, and in coloring soaps. It is also used with ultramarine blue to produce a green pigment
Cadmii Sulphas, $CdSO_4.4H_2O$ Cadmium Sulphate	Colorless crystals; soluble in water. It is used as an astringent and antiseptic, and has been employed in eye washes to replace zinc sulphate. Cadmium sulphate is also used in producing normal cadmium electric cells

CHAPTER LII

MANGANESE, IRON, CHROMIUM, AND URANIUM

Mn; 54.93. Fe; 55.84. Cr; 52.0 U; 238.2

THESE four metals form a group exhibiting some chemical and physical analogies. They unite with oxygen, producing basic oxides.

Manganese, Mn; 54.93

Manganese is a corruption of the word "magnesia" since manganese dioxide was once called "magnesia nigra". It is found as a mineral quite extensively in the state of black oxide, as *pyrolusite*, *braunite*, and *hausmannite*. The carbonate also is sometimes found. The metal is very hard and brittle, is gray and lustrous in appearance, has a specific gravity from 7.2 to 7.8 and melts at 1260° C.; when powdered, it decomposes water readily. A very pure product is obtained by the Goldschmidt method, whereby manganese dioxide is reduced with finely divided metallic aluminum at high temperatures. With oxygen it forms five—possibly seven—compounds. The *monoxide*, or *manganous oxide*, MnO, is of a light green color, and is the oxide present in or corresponding to manganous salts. The *sesquioxide*, Mn_2O_3, is black or dark brown, when in the hydrated state; the magnetic oxide, or *manganous-manganic oxide*, Mn_3O_4, is the native hausmannite and is brown-black in color; the dioxide, MnO_2, is black; and the permanganic oxide, Mn_2O_7, is, when in the free state, a very unstable dark reddish-brown liquid. The monoxide is a stable base, the sesquioxide feebly basic, and the dioxide when acted upon by acids yields manganous salts, while oxygen is evolved. The highest oxide is acid-forming, yielding permanganic acid, $HMnO_4$, the salts of which are known as permanganates. There are also manganates corresponding to an acid of the formula, H_2MnO_4.

Tests for Manganese Compounds

When in solution, manganous compounds yield a salmon-colored precipitate with ammonium sulphide T.S. This precipitate is dissolved by acetic acid.

A very delicate test for the detection of manganese is the so-called Crum's test. This involves the formation of the purplish pink permanganic acid by evaporation of the manganese compound with nitric acid and a trace of red lead and by subsequent dilution with water.

Permanganates—Solutions of permanganates acidulated with sulphuric acid are decolorized by hydrogen dioxide T.S., sodium bisulphite T.S., or oxalic acid T.S.

POTASSII PERMANGANAS. U. S. Potassium Permanganate

[Pot. Permang.]

This is the most important official compound of manganese. It is considered under the potassium compounds (page 612).

MANGANI CITRAS SOLUBILIS. N. F. Soluble Manganese Citrate

[Mangan. Cit. Sol.—MANGANESE AND SODIUM CITRATE]

Manganous citrate rendered soluble by the presence of sodium citrate. It corresponds, when dried to constant weight at 120° C., to not less than 48 per cent and not more than 52 per cent of $Mn_3(C_6H_5O_7)_2$(542.93).

Manganese citrate is prepared by the action of citric acid on manganese hydroxide. It is then rendered soluble by the aid of sodium citrate.

Description and Physical Properties—Soluble Manganese Citrate occurs as a yellowish or pinkish-white powder, or as translucent scales; odorless, and having a slightly bitter and astringent taste. It is permanent in the air.

One Gm. dissolves slowly in about 4 cc. of water; slightly more soluble in boiling water, nearly insoluble in alcohol.

Tests for Identity—An aqueous solution of Soluble Manganese Citrate (1 in 20) is slightly acid or slightly alkaline to litmus, but does not redden phenolphthalein T.S.

When strongly heated, it chars and finally leaves a residue which effervesces with acids and imparts an intensely yellow color to a non-luminous flame.

An aqueous solution of Soluble Manganese Citrate (1 in 20) rendered alkaline with ammonia water, yields a salmon-colored precipitate on warming with ammonium sulphide T.S.

Ten cc. of an aqueous solution of Soluble Manganese Citrate (1 in 20), slightly acidulated with acetic acid and mixed with 2 cc. of calcium chloride T.S., remains clear while cold, but yields a white, crystalline precipitate when heated to boiling.

Tests for Purity—Separate portions of 10 cc. each of an aqueous solution of Soluble Manganese Citrate (1 in 100), when acidulated with hydrochloric acid, are not more than slightly reddened by potassium thiocyanate T.S. (*iron*); nor rendered turbid at once by barium chloride T.S. (*sulphate*); nor show more than an opalescence with silver nitrate T.S. when acidulated with nitric acid (*chloride*).

Mix about 0.5 Gm. of Soluble Manganese Citrate with 5 cc. of sulphuric acid in a porcelain dish previously rinsed with sulphuric acid, protect the mixture from dust and heat it for fifteen minutes on a water bath; no color darker than yellow develops (*tartrates or other readily carbonizable substances*).

An aqueous solution of Soluble Manganese Citrate does not respond to the test for heavy metals (see page 1519).

Assay—Dissolve about 0.5 Gm. of Soluble Manganese Citrate, previously dried to constant weight at 120° C. and accurately weighed, in 100 cc. of distilled water, add 50 cc. of solution of hydrogen dioxide, and 10 cc. of ammonia water, and boil the mixture for several minutes. Collect the precipitate on a filter, wash it thoroughly with hot distilled water, dry and ignite to constant weight. The weight of the manganous-manganic oxide (Mn_3O_4) so obtained is not less than 20.23 per cent or more than 21.92 per cent of the weight of the salt taken, corresponding to not less than 48 per cent or more than 52 per cent of $(Mn_3C_6H_5O_7)_2$.

Each Gm. of manganous-manganic oxide is equivalent to 2.3728 Gm. of $Mn_3(C_6H_5O_7)_2$.
This assay is explained on page 1481.

N. F. Preparation—Liquor Ferri Peptonati et Mangani.

Uses—It is used as a tonic, especially in anemia in doses of three to five grains (0.2 to 0.3 Gm.).

MANGANI GLYCEROPHOSPHAS SOLUBILIS. N. F. Soluble Manganese Glycerophosphate

[**Mangan. Glycerophos. Sol.**—Soluble Manganous Glycerinophosphate]

Manganous Glycerophosphate rendered soluble by the aid of citric acid. It contains not less than 70 per cent nor more than 75 per cent of $MnC_3H_7PO_6$(225.04).

Description and Physical Properties—Soluble Manganese Glycerophosphate occurs as a yellowish or pinkish white powder, odorless, and having an acid taste.

One gram dissolves in 4 cc. of water at 25° C. The aqueous solution is strongly acid to litmus and becomes turbid on heating. Alcohol dissolves the citric acid, leaving a residue which is nearly insoluble in water.

Tests for Identity—Add an excess of ammonium sulphide T.S. to an aqueous solution of Soluble Manganese Glycerophosphate; on standing, it yields a salmon-colored precipitate soluble in acetic acid.

No yellow turbidity is produced immediately on mixing 5 cc. of an aqueous solution (1 in 20) with 10 cc. of ammonium molybdate T.S. (*phosphate*), but on prolonged standing, or on heating, a yellow precipitate is formed.

Heat a powdered mixture of about 0.1 Gm. of Soluble Manganese Glycerophosphate and about 0.5 Gm. of potassium bisulphate; pungent vapors of acrolein are evolved.

Tests for Purity—Separate portions of 10 cc. each of an aqueous solution of Soluble Manganese Glycerophosphate (1 in 20) are not rendered more than slightly turbid by barium chloride T.S. when mixed with a few drops of hydrochloric acid (*sulphate*); nor by silver nitrate T.S., after acidulation with nitric acid (*chloride*).

Add a few drops of hydrochloric acid and 1 cc. of chlorine T.S. to 10 cc. of an aqueous solution of Soluble Manganese Glycerophosphate (1 in 200) and boil; no reddish color is produced in the liquid by potassium thiocyanate T.S. after cooling (*iron*).

An aqueous solution of Soluble Manganese Glycerophosphate does not respond to the test for heavy metals (see page 1519).

Assay—Dissolve about 0.5 Gm. of Soluble Manganese Glycerophosphate, accurately weighed in 100 cc. of distilled water, add 10 cc. of ammonia water and 5 cc. of ammonium sulphide T.S., and boil the mixture until the precipitate formed has become greenish. Allow the precipitate to settle, then transfer it to a filter, wash with hot distilled water containing a few drops of ammonium sulphide T.S., dry the filter and contents and incinerate them in an open crucible, first at a low temperature and then at a strong red heat, until the weight is constant. The residue of manganese-

manganic oxide (Mn_3O_4) so obtained is not less than 23.7 per cent or more than 25.4 per cent of the weight taken, corresponding to not less than 70 per cent or more than 75 per cent of $MnC_3H_7PO_6$.

Each Gm. of manganous-manganic oxide is equivalent to 2.95 Gm. of $MnC_3H_7PO_6$.

This assay is explained on page 1481.

N. F. Preparation—Elixir Glycerophosphatum Compositum.

Uses—It is used as a nervine and blood tonic in doses of three to five grains (0.2 to 0.32 Gm.).

MANGANI HYPOPHOSPHIS. N. F. Manganese Hypophosphite

[Mangan. Hypophos.]

Manganese Hypophosphite contains not less than 97 per cent of $Mn(PH_2O_2)_2.H_2O$ (203.06).

Preparation—It may be prepared by dissolving manganese carbonate in hypophosphorous acid, in molecular proportion and crystallizing from the hot aqueous solution or by boiling together solutions of barium hypophosphite and manganese sulphate, filtering out the barium sulphate, evaporating the filtrate and crystallizing.

The equation for the above reaction is expressed as follows:

$$\underset{\text{manganous carbonate}}{MnCO_3} + \underset{\text{hypophosphorous acid}}{2HPH_2O_2} = \underset{\text{manganous hypophosphite}}{Mn(PH_2O_2)_2} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—Manganese Hypophosphite is a pink, granular or crystalline powder; odorless and nearly tasteless; permanent in the air.

It is freely soluble in water; insoluble in alcohol.

Tests for Identity—An aqueous solution of the salt (1 in 20) is neutral or acid to litmus and yields with ammonium sulphide T.S. a salmon-colored precipitate of manganese sulphide, soluble in acetic acid.

When strongly heated in a dry test tube, the salt evolves spontaneously inflammable hydrogen phosphide and finally leaves a residue of manganous pyrophosphate.

When an aqueous solution of the salt (1 in 20) acidulated with hydrochloric acid, is added, drop by drop, with agitation, to an excess of mercuric chloride T.S. a white precipitate of mercurous chloride is formed, and, upon the further addition of the solution of Manganese Hypophosphite, the precipitate becomes gray from reduction to metallic mercury.

Tests for Purity—Add about 0.5 Gm. of the salt to 5 cc. of acetic acid; no effervescence is produced (*carbonate*).

Boil 0.25 Gm. of the salt with 10 cc. of sodium hydroxide T.S.: a white precipitate is formed which gradually acquires a brown color on exposure to the air. The filtrate from this mixture, after being slightly acidulated with hydrochloric acid, boiled for one minute, and then rendered alkaline with ammonia water, yields no precipitate upon the addition of magnesia mixture T.S. (*phosphate*).

Dissolve 1 Gm. of the salt in 20 cc. of diluted hydrochloric acid with the aid of heat, and then add 1 cc. of barium chloride T.S.; not more than a slight turbidity is produced (*sulphate*).

Dissolve 0.5 Gm. of Manganese Hypophosphite in 10 cc. of hot distilled water, add 10 cc. of solution of hydrogen dioxide and 10 cc. of sodium hydroxide T.S., boil for one minute, then render slightly acid with acetic acid and again warm. Now cool, filter, and add 1 cc. of ammonium oxalate T.S. to 10 cc. of the filtrate; no turbidity is produced within five minutes (*calcium*).

Pour 5 cc. of an aqueous solution of the salt (1 in 30) into an evaporating dish containing 3 cc. of nitric acid diluted with about 10 cc. of distilled water, and evaporate to dryness on a water bath; the residue meets the requirements of the test for *arsenic* (see page 1512).

Assay—Dissolve about 1 Gm. of Manganese Hypophosphite, accurately weighed, in 30 cc. of boiling distilled water in a 250 cc. measuring flask. Add 25 cc. of solution of hydrogen dioxide and 15 cc. of sodium hydroxide T.S. and heat for ten minutes on a water bath with frequent agitation. Cool, add distilled water to make the volume exactly 250 cc., mix well and filter through a dry filter. Evaporate 25 cc. of the clear filtrate to dryness with 10 cc. of nitric acid, dissolve the residue in 10 cc. of nitric acid and again evaporate to dryness; then dissolve the residue in 10 cc. of distilled water, transfer it to a 100 cc. flask with the aid of a few cc. of distilled water, add a drop of phenolphthalein T.S. and sufficient sodium hydroxide T.S. (free from chloride) to produce a pink color, then add 50 cc. of tenth-normal silver nitrate and agitate the mixture well. Now gradually add zinc oxide (free from chloride) in small portions, agitating vigorously after each addition until the liquid is neutral to litmus. Then add distilled water to make 100 cc., agitate the mixture thoroughly, filter through a dry filter, collect 50 cc. of the filtrate, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate to the production of a permanent red color.

Each cc. of tenth-normal silver nitrate used corresponds to 0.003384 Gm. of $Mn(PH_2O_2)_2.H_2O$. Each Gm. of Manganese Hypophosphite corresponds to not less than 286.6 cc. of tenth-normal silver nitrate.

This assay is explained on page 1464.

Preserve it in well-closed containers.

N. F. Preparations—Liquor Hypophosphitum Compositus; Syrupus Hypophosphitum Compositus.

Uses—Used as a tonic and alterative in doses of three to five grains (0.2 to 0.32 Gm.). Usually in the form of the compound Syrup of Hypophosphites.

Unofficial Salts of Manganese

Mangani Arsenas, $MnHAsO_4$ Manganese Arsenate	A reddish-white powder; slightly soluble in water. It is used as an alterative and tonic in doses of from $\frac{1}{30}$ to $\frac{1}{6}$ grain (0.002 to 0.01 Gm.)
Mangani Carbonas, $MnCO_3$ Manganese Carbonate	A rose-colored, crystalline powder; insoluble in water. It is used in the manufacture of other manganous compounds and in medicine as a tonic; dose, 5 to 15 grains (0.3 to 1 Gm.)
Mangani Chloridum, $MnCl_2$ Manganous Chloride	Deliquescent, rose-colored crystals; soluble in water. It is used in dyeing, removing color from glass, and in regenerating manganese dioxide. It is also used in solution as a mouth wash and gargle for syphilitic ulcers
Mangani Citras, $MnHC_6H_5O_7$ Manganese Citrate	A white powder; soluble in water. It is used in medicine as a tonic and astringent
Mangani Oxalas, $2MnC_2O_4.5H_2O$ Manganese Oxalate	A white, crystalline powder; slightly soluble in water. It is used as a varnish drier and in the manufacture of metallic manganese
Mangani Sulphas, $MnSO_4$ (N. F. IV)	Rose-colored, translucent, prisms, soluble in water. It is used as a cholagogue and tonic in doses of 3 to 20 grains
Mangani Tartras, $MnC_4H_4O_6$ Manganese Tartrate	A white powder; very slightly soluble in water. It is made by precipitation from solutions of manganous chloride and neutral potassium tartrate

Iron, Fe; 55.84

Iron is from words of several languages pertaining to anything strong, hard or unyielding. It is the most useful and abundant of the metals, is widely diffused in nature, and is found not only in the mineral kingdom, but in animal and vegetable products as well.

Iron is a hard, malleable, ductile, and tenacious metal, of a grayish-white color and fibrous texture, a slightly styptic taste, having a sensible odor when rubbed. Its specific gravity is 7.8. It is combustible, and, when heated to whiteness, burns in atmospheric air, and with brilliant scintillations in oxygen. At a red heat its surface is converted into black oxide, and at common temperatures, by the combined agency of air and moisture, it becomes covered with a reddish matter, called *rust*, which is hydrated ferric oxide. All commercial forms of iron contain carbon partly in the free state and partly in the form of carbide. *Wrought iron* contains the lowest amount of carbon, *cast iron* the highest amount, and *steel* an intermediate proportion of carbon. Iron combines with all the non-metallic elements except hydrogen and nitrogen, and with most of the metals. It forms three well-known oxides.

Ferrous oxide (FeO) is an unstable oxide of iron of little importance. Ferric oxide (Fe_2O_3) is the most important oxide of iron. It occurs in nature as hematite and can be made by heating ferric hydroxide. Ferroso-ferric oxide (Fe_3O_4) is the magnetic oxide of iron that occurs in nature as magnetite. The black scale that forms when iron is heated in air or steam is of this composition.

The following discussion of this use of iron in medicine is from the N. N. R. (1925), and is worthy of the consideration of the pharmacy student:

Iron and Iron Compounds

Iron is used (1) in the form of metallic or elementary iron (reduced iron, U. S. P.); (2) in the ferrous or unoxidized form (ferrous carbonate); (3) in the trivalent or oxidized form, the ferric compounds (tincture of ferric chloride); and (4) complex compounds of iron (scale salts of iron).

Complex iron compounds are those whose solutions do not respond to the ordinary tests for ferrous or ferric ions because in them the iron is part of a radicle. Complex compounds of iron do not have the astringent taste of simple iron solutions. Their permanency differs widely; while some are converted to simple ionic iron by action of dilute acids (soluble ferric phosphate, syrup of citro-iodide of iron, etc.), others resist treatment with strong acids or with alkalies. The complex iron compounds occurring naturally in animal

and vegetable tissues (which are often termed food irons) belong generally to the more resistant class, while the complex iron compounds produced artificially are as a rule decomposed rather readily. There is, however, no sharp line of distinction between the natural complex iron compounds and the artificially produced ones, nor is there any good evidence that they differ in therapeutic action. Salts of iron which give the iron test directly are classed as inorganic iron, whatever their acid radicles may be; true iron albuminate and iron peptonate are inorganic iron compounds.

Solutions of ferric iron are used externally as styptics. Ferric solutions may be used for their astringent effects, internally, and as a gargle. The principal use of iron, however, is in the treatment of anemia and chlorosis. For this purpose, the ferrous salts are usually preferred to the ferric salts, as they are not so caustic and hence are less likely to disturb the stomach.

Tests for Iron Salts

Ferrous or ferric compounds in solution yield a black precipitate with ammonium sulphide T.S. This precipitate is dissolved by cold, diluted hydrochloric acid with the evolution of hydrogen sulphide.

Ferric salts in solution yield a dark blue precipitate with potassium ferrocyanide T.S. With an excess of sodium hydroxide T.S. a reddish-brown precipitate is formed. Solutions of ferric salts produce with potassium thiocyanate T.S. a deep red color which is not destroyed by diluted mineral acids.

Ferrous salts in solution yield a dark blue precipitate with potassium ferricyanide T.S. This precipitate is insoluble in diluted hydrochloric acid, but is decomposed by sodium hydroxide T.S. Solutions of ferrous salts yield with sodium hydroxide T.S. a white precipitate, the color rapidly changing to green.

FERRUM. U. S. Iron

[Ferr.]

Metallic iron [Fe = 55.84] in the form of fine, bright wire.

Iron, when employed in pharmaceutical operations, should be of the purest kind; hence the pharmacopœias generally direct it, when wanted in small masses, to be in the form of *iron wire*, which is necessarily made from the purest iron, because it is the softest and most ductile, and readily cut into pieces. Such wire is very flexible and without elasticity.

The wire clippings and the ends of card teeth obtained from the manufacturers of cotton carding machines are frequently used for making iron preparations. They are very convenient and it may be incidentally mentioned that they are sometimes used as a substitute for sand in sand baths. Iron scraps and waste from steel pen factories are also used to make preparations of iron.

U. S. P. Preparation—Syrupus Ferri Iodidi.
N. F. Preparation—Syrupus Calcii Iodidi.

FERRUM REDUCTUM. U. S. Reduced Iron

[**Ferr. Reduct.**—Ferrum Redactum, Iron by Hydrogen, Quevenne's Iron]

Reduced Iron is obtained by the action of hydrogen upon ferric oxide and contains not less than 90 per cent of metallic iron [Fe = 55.84].

Preparation—Reduced iron is prepared by treating ferric oxide (Fe_2O_3) with hydrogen in a heated reduction tube, until the reduction is complete

(see Remington's Practice of Pharmacy, Sixth edition, page 862, for full details).

The reaction for its production is illustrated by the following equation:

$$\underset{\text{ferric oxide}}{Fe_2O_3} + \underset{\text{hydrogen}}{6H} = \underset{\text{iron}}{2Fe} + \underset{\text{water}}{3H_2O}$$

Imitations of "reduced iron" have been offered for import in recent years. One of these differs from the official product by being crystalline and by not being so fine a powder. This has not been admitted for entry since it did not comply with the U. S. P. specifications. It has evidently been prepared by electric deposition or by some mechanical process. One product is termed *alcoholized iron* in which the word alcohol has its original Arabic meaning of "finely divided".

The value of Reduced Iron is largely dependent upon its physical characteristics, hence the new tests, requiring it to pass through a No. 100 sieve and be amorphous when viewed under a microscope. A test has also been added requiring "glowing" when the substance is heated in a crucible and thrown into the air.

Description and Physical Properties—An odorless, grayish-black, lusterless powder, all of which must pass through a No. 100 sieve. When viewed under a lens having a magnifying power of one hundred diameters, Reduced Iron appears as an amorphous powder, free from crystalline particles. It is stable in dry air.

Reduced Iron is insoluble in water and in alcohol.

Tests for Identity—Heat about 1 Gm. of Reduced Iron in a porcelain crucible with a small Bunsen flame until it assumes a bluish-black color without glowing. Then quickly pour it from the crucible: the particles of iron will glow brightly as they fall through the air.

Tests for Purity—Shake 1 Gm. of Reduced Iron with 5 cc. of distilled water, and filter: the filtrate does not change the color of litmus paper.

Treat 1 Gm. of Reduced Iron with 20 cc. of diluted sulphuric acid and when the reaction subsides, heat gently until no more gas is evolved. Filter, wash the residue with distilled water until the washings cease to react for sulphate, dry at 110° C. to constant weight, and weigh. The weight of the residue should not exceed 0.010 Gm.

One Gm. of Reduced Iron mixed with 20 cc. of diluted sulphuric acid in a flask causes the evolution of nearly odorless hydrogen gas, which does not affect paper moistened with lead acetate T.S. within two minutes (*sulphide*).

Add 20 cc. of diluted sulphuric acid to 0.5 Gm. of Reduced Iron contained in a small, covered beaker, and after the reaction has subsided somewhat, warm the liquid on a water bath until the reaction ceases. Pass the solution through a small filter to collect any undissolved residue, rinse the beaker with distilled water, add the rinsings to the filter, and then wash the residue with distilled water until free from acid reaction. Transfer the residue to the beaker by rinsing it back, and after adding about 0.25 Gm. of potassium chlorate and 5 cc. of hydrochloric acid, slowly evaporate the solution to dryness on a water bath. Dissolve the residue in sufficient distilled water to measure 50 cc., add 5 cc. of this solution to 5 cc. of a saturated solution of sulphurous acid, and heat the liquid on a water bath for fifteen minutes, or until all traces of sulphurous acid have been removed: the resulting solution meets the requirements of the test for *arsenic*, page 1512.

Assay—Triturate thoroughly about 1 Gm. of Reduced Iron, weigh accurately, place it in a 100 cc. flask, and add 10 Gm. of finely powdered corrosive mercuric chloride and 50 cc. of boiling distilled water. Boil the mixture for five minutes, shaking it frequently, then fill the flask to the 100 cc. mark with distilled water, recently boiled and cooled, and cool the mixture to room temperature. Again fill the flask to the mark with distilled water, stopper, agitate the contents well, and allow to stand for a few minutes. Now filter the contents of the flask, and immediately titrate 20 cc. of the filtrate to which has been added 20 cc. of diluted sulphuric acid, with tenth-normal potassium permanganate until a permanent pink color is produced. Each cc. of tenth-normal potassium permanganate corresponds to 0.005584 Gm. of Fe.

This assay is explained on page 1474.

Preserve in well-closed containers.

N. F. Preparations—Extractum Ferri Pomatum; Pilulæ Ferri Iodidi; Pilulæ Ferri, Quininæ, Strychninæ et Arseni Fortiores; Pilulæ Ferri, Quininæ, Strychninæ et Arseni Mites.

History—Reduced iron was first produced by Theodore Quevenne, head pharmacist of the Paris Charity Hospital about 1850.

Uses—Powder of iron, or reduced iron, is one of the best of the chalybeate tonics. It is generally given in pill form, in doses of one to six grains (0.065 to 0.38 Gm.). It has been used for the preparation of syrup of ferrous iodide, replacing the iron wire and hastening the reaction. An excellent form of administering it is in combination with chocolate in the form of lozenges.

Average dose—1 grain (0.06 Gm.).

FERRI CARBONAS SACCHARATUS. U. S. Saccharated Ferrous Carbonate [Ferr. Carb. Sacch.]

Saccharated Ferrous Carbonate contains not less than 15 per cent of $FeCO_3$ (115.85).

	Metric	Alternative
Ferrous Sulphate	**50 Gm.**	5 oz. av.
Sodium Bicarbonate	**35 Gm.**	3½ oz. av.
Lactose	**10 Gm.**	1 oz. av.
Sucrose, in fine powder,		
Diluted Sulphuric Acid,		
Distilled Water, each, a sufficient quantity,		
To make	**100 Gm.**	10 oz. av.

Dissolve 8.5 Gm. [372 gr.] of sucrose in 200 cc. [20 fl. oz.] of hot distilled water, and then dissolve the ferrous sulphate in that solution. Add from three to five drops of diluted sulphuric acid, and filter. Dissolve the sodium bicarbonate in 500 cc. [3 pints] of distilled water at a temperature not exceeding 50° C., and filter. To the solution of sodium bicarbonate contained in a flask having a capacity of about 1000 cc. [6 pints] gradually add the solution of ferrous sulphate, and mix thoroughly by rotating the flask. Fill the flask with boiling distilled water, cork it loosely, and set the mixture aside. When the precipitate has subsided, draw off the clear supernatant liquid by means of a siphon, fill the flask again with hot distilled water, and shake it. Again draw off the liquid, and repeat the washing with hot distilled water in the same manner until the decanted liquid gives merely a slight cloudiness with barium chloride T.S. Drain the precipitate, transfer it to a porcelain dish containing 61.5 Gm. [6 oz. av. 66 gr.] of sucrose and 10 Gm. [1 oz. av.] of lactose, and mix intimately. Evaporate the mixture to dryness on a water bath, reduce it to a powder, weigh, and mix intimately with it, if necessary, enough well-dried sucrose to make the product weigh 100 Gm. [10 oz. av.]. To minimize oxidation make this preparation in the shortest possible time.

In this preparation ferrous carbonate is formed, sodium sulphate remaining in solution. Sodium bicarbonate is preferred because the evolution of carbonic acid during the decomposition measurably prevents oxidation; it would have been an improvement to use syrup in the solutions to protect them still further.

The object of boiling the water for washing the precipitate is to expel the air, so that the ferrous carbonate may escape its oxidizing action; the evaporation of the mixture should be conducted as rapidly as possible, for the same reason.

$$\underset{\text{ferrous sulphate}}{FeSO_4} + \underset{\text{sodium bicarbonate}}{2NaHCO_3} = \underset{\text{sodium sulphate}}{Na_2SO_4} + \underset{\text{ferrous carbonate}}{FeCO_3} + \underset{\text{water}}{H_2O} + \underset{\text{carbon dioxide}}{CO_2}$$

Description and Physical Properties—A greenish-brown, odorless powder, which gradually becomes oxidized by contact with air.

Saccharated Ferrous Carbonate is only partially soluble in water.

Tests for Identity—When treated with hydrochloric acid, it dissolves with copious evolution of carbon dioxide, a clear, greenish-yellow liquid resulting.

Dissolve 1 Gm. of Saccharated Ferrous Carbonate in 5 cc. of hydrochloric acid, and dilute the solution with distilled water until it measures 100 cc.: this solution responds to the reactions for ferrous salts, page 710.

Tests for Purity—A 10 cc. portion of the solution prepared as above, when diluted with distilled water to 50 cc. shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid, page 1520.

Assay—Dissolve about 2 Gm. of Saccharated Ferrous Carbonate, accurately weighed, in 15 cc. of diluted sulphuric acid, and dilute the solution with distilled water to about 100 cc. Titrate immediately with tenth-normal potassium dichromate, potassium ferricyanide T.S. being used as indicator. Each cc. of tenth-normal potassium dichromate corresponds to 0.01159 Gm. of $FeCO_3$.

This assay is explained on page 1472.

Preserve in small, well-stoppered bottles, exposed to light.

Uses—Saccharated ferrous carbonate is used as a hematinic, in doses of four grains (0.25 Gm.).

MASSA FERRI CARBONATIS. U. S. Mass of Ferrous Carbonate

[**Mass. Ferr. Carb.**—Vallet's Mass]

Mass of Ferrous Carbonate contains not less than 35 per cent of $FeCO_3$. (115.85). (See page 487 for the formula.)

Assay—Dissolve about 1 Gm. of Mass of Ferrous Carbonate, accurately weighed, in 15 cc. of diluted sulphuric acid, dilute the solution with distilled water to about 100 cc., and immediately titrate with tenth-normal potassium dichromate, potassium ferricyanide T.S. being used as indicator. Each cc. of tenth-normal potassium dichromate corresponds to 0.01159 Gm. of $FeCO_3$.

This assay is explained on page 1472.

This preparation consists of ferrous carbonate preserved from oxidation by contact with syrup and honey. The reaction is expressed as follows:

$$\underset{\text{ferrous sulphate}}{FeSO_4} + \underset{\text{sodium carbonate}}{Na_2CO_3} = \underset{\text{ferrous carbonate}}{FeCO_3} + \underset{\text{sodium sulphate}}{Na_2SO_4}$$

Uses—Mass of ferrous carbonate is widely known as *Vallet's Mass;* it is a valuable chalybeate tonic, and is administered in pill form, in doses of four grains (0.25 Gm.). Ferrous carbonate is also official in the U. S. P. under the title *Pilulæ Ferri Carbonatis*, see Chapter 487. A powdered Vallet's Mass is also obtainable.

A mixture of dried ferrous sulphate and potassium or sodium carbonate in glycerin is a commercial product. Under these conditions there is no reaction and to avoid surface oxidation a small amount of liquid petrolatum is added, which floats on the surface and makes an air-tight seal. This mixture is to be well shaken, then added to water, before administering, when the reaction occurs and freshly precipitated ferrous carbonate is made available.

A formula for a *liquid ferrous carbonate*, or *nascent ferrous carbonate*, of this character, was suggested by M. I. Wilbert, as given below. Advantage is taken of the solvent properties of glycerin to inhibit the reaction and it must be well diluted with water before administration.

Granulated Ferrous Sulphate	3.2 cc.
Distilled Water	1.5 cc.
Potassium Carbonate	1.6 Gm.
Glycerin, to make	100 cc.

Dissolve the ferrous sulphate in the water, add 50 cc. of Glycerin and then the potassium carbonate, dissolved in the remainder of the glycerin. Each 5 cc. of this liquid is the equivalent of an official pill of ferrous carbonate.

FERRI CHLORIDUM. U. S. Ferric Chloride

[Ferr. Chlor.—Iron Perchloride, Sesquichloride of Iron]

Ferric Chloride contains $FeCl_3$ (162.22), in a hydrated form, corresponding to not less than 20 per cent of Fe (55.84).

Preparation—The Pharmacopœia no longer includes a process but the U. S. P. VIII gave the following:

	Metric	Alternative
Solution of Ferric Chloride	**100 Gm.**	10 oz. av.
To make	**40 Gm.**	4 oz. av.

Evaporate the solution of ferric chloride on a water bath until it weighs 40 Gm. [4 oz. av.]; then set it aside in a glass-covered vessel until it forms a crystalline mass. Lastly, break the salt into pieces, and keep it in glass-stoppered bottles, protected from light.

Description and Physical Properties—Orange-yellow, or brown-yellow, crystalline pieces. It is odorless, or has a faint odor of hydrochloric acid, and a strongly styptic taste. It is very deliquescent.

One Gm. of Ferric Chloride is soluble in 0.2 cc. of water at 25° C. It is freely soluble in alcohol, and is soluble in glycerin and in ether.

At about 35.5° C. the salt fuses to a reddish-brown liquid. When strongly heated, it is decomposed, leaving a residue of ferric oxide.

Tests for Identity—Ferric Chloride responds to the reactions for ferric iron, page 710, and for chlorides, page 567.

Tests for Purity—An aqueous solution of Ferric Chloride, made by dissolving 10 Gm. of the salt in 15 cc. of distilled water, complies with the tests for purity under *Liquor Ferri Chloridi*, omitting the test for hydrochloric acid.

Assay—Dissolve about 1 Gm. of Ferric Chloride, accurately weighed in a stoppered weighing-bottle, in 25 cc. of distilled water, transfer to a glass-stoppered flask or bottle, add 3 cc. of hydrochloric acid and 4 Gm. of potassium iodide, stopper the container securely, and allow the mixture to stand for thirty minutes at a temperature of 40° C. Cool this solution, then dilute it with 100 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

This assay is explained on page 1466.

Preserve in well-closed glass containers protected from light.

Uses—Ferric chloride is used externally as an astringent and styptic, and internally as a chalybeate tonic, in doses of one to five grains (0.065 to 0.32 Gm.).

LIQUOR FERRI CHLORIDI. U. S. Solution of Ferric Chloride

[Liq. Ferr. Chlor.—Solution of Iron Perchloride]

Solution of Ferric Chloride contains ferric chloride [$FeCl_3 = 162.22$], corresponding to not less than 10 per cent and not more than 11 per cent of Fe.

The Pharmacopœia no longer contains a process of manufacture but the U. S. P. IX formula was as follows:

	Metric	Alternative
Iron, in the form of fine, bright wire and cut into small pieces	**125 Gm.**	2 oz. av. 325 gr.
Hydrochloric Acid	**680 Gm.**	12 fl. oz. 3 fl. dr.
Nitric Acid,		
Distilled Water, each, a sufficient quantity,		
To make	**1000 Gm.**	1 pint

Introduce the iron wire into a flask having a capacity of about 2000 cc. [3 pints], pour upon it a mixture of 420 Gm. [or measure 7 fl. oz. 7 fl. dr.] of hydrochloric acid and 250 cc. [5½ fl. oz.] of distilled water and heat the mixture on a water bath for not less than one hour and fifteen minutes, or until effervescence ceases; then boil the liquid, filter it through paper, and, having rinsed the flask and iron wire with a little hot distilled water, pass the rinsings through the filter. To the filtered liquid add 220 Gm. [or measure 4 fl. oz.] of

hydrochloric acid, then add the mixture slowly and gradually in a stream to 65 Gm. [or measure 468 min.] of nitric acid contained in a tared, capacious porcelain vessel, and warm gently. If the solution has acquired a black color, continue the addition of nitric acid, drop by drop, until red fumes are no longer evolved and the solution assumes a clear, reddish-brown color. After effervescence ceases, heat on a sand bath, stirring occasionally until the liquid is free from nitric acid, as indicated by the test given below. During the heating add distilled water from time to time to maintain about the original volume. Finally add the remaining 40 Gm. [or measure 6 fl. oz.] of hydrochloric acid and enough distilled water to make the Solution weigh 1000 Gm. [or measure 1 pint].

In the first step of the process, ferrous chloride is produced; thus:

$$\underset{\text{iron}}{Fe_2} + \underset{\text{hydrochloric acid}}{4HCl} = \underset{\text{ferrous chloride}}{(FeCl_2)_2} + \underset{\text{hydrogen}}{4H}$$

Ferrous chloride is converted into ferric chloride by the addition of nitric and hydrochloric acids; thus:

$$\underset{\text{ferrous chloride}}{6FeCl_2} + \underset{\text{hydrochloric acid}}{6HCl} + \underset{\text{nitric acid}}{2HNO_3} = \underset{\text{ferric chloride}}{6FeCl_3} + \underset{\text{nitrogen dioxide}}{N_2O_2} + \underset{\text{water}}{4H_2O}$$

If this solution, when finished, has a black color, it is due to incomplete oxidation, and the remedy is to heat it to boiling in a capacious dish, adding a few drops of nitric acid until the color changes to a clear ruby-red and effervescence ceases. If a brown precipitate is deposited upon dilution or standing, deficiency of hydrochloric acid is indicated, and the solution must be heated, and a few drops of the acid added until the precipitate is dissolved; but a large excess of hydrochloric acid must be avoided or the solution will prove unsatisfactory in the preparation of tincture of ferric citro-chloride of the N. F. (see page 389), producing a reddish instead of a green colored solution. The U. S. P. has included a test to limit the amount of free acid.

Description and Physical Properties—A yellowish-brown liquid, having a faint odor of hydrochloric acid and an acid reaction.

It is miscible in all proportions with alcohol.

Specific gravity: from 1.29 to 1.32 at 25° C.

Tests for Identity—An aqueous dilution of the Solution (1 in 10) responds to the reactions for ferric iron, page 710, and for chlorides, page 567.

Tests for Purity—Weigh about 4 cc. of the Solution, dilute to 100 cc. with distilled water, and precipitate the iron completely by adding an excess of ammonia T.S., and filter: the filtrate is colorless. One-half of the filtrate does not yield a precipitate with hydrogen sulphide T.S. (*zinc, lead, or copper*).

The residue obtained upon evaporation and ignition of the remaining half of the filtrate does not exceed 0.1 per cent (*salts of the fixed alkalies*).

Mix 1 cc. of the Solution with 10 cc. of ferrous sulphate T.S. and superimpose the mixture upon 5 cc. of sulphuric acid contained in a test tube: the line of contact does not assume a brown or reddish-brown color (*nitrate*).

Add a few drops of freshly prepared potassium ferricyanide T.S. to an aqueous dilution of the Solution (about 1 in 20): a brown color is produced which does not at once turn green or greenish-blue (*ferrous salts*).

Add 10 cc. of distilled water and 50 cc. of tenth-normal silver nitrate to about 0.5 Gm. of Solution of Ferric Chloride, accurately weighed, shake vigorously, then add 2 cc. of nitric acid and sufficient distilled water to measure exactly 100 cc., and mix well. Pass the mixture through a filter not previously moistened (rejecting the first 10 cc. portion), and determine the excess of silver nitrate in 50 cc. of the filtrate by titration with tenth-normal potassium thiocyanate. The percentage of chlorine found is not less than 3 per cent and not more than 5 per cent in excess of that required to combine as ferric chloride with the iron present. The percentage of iron (see assay below) multiplied by 1.9, gives the percentage of chlorine combined as ferric chloride (*free hydrochloric acid*). Each cc. of tenth-normal silver nitrate corresponds to 0.003546 Gm. of Cl.

Assay—Transfer about 2 Gm. of Solution of Ferric Chloride to a tared flask, stopper, weigh accurately, add 5 cc. of hydrochloric acid, 25 cc. of distilled water and about 3 Gm. of potassium iodide. Securely stopper the flask, and allow the mixture to stand for thirty minutes at a temper-

ature of 40° C. Cool the liquid, dilute it with 100 cc. of distilled water, and then titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

This assay is explained on page 1467.

Preserve in glass-stoppered bottles, protected from light.

U. S. P. Preparation—Tinctura Ferri Chloridi.

N. F. Preparations—Ferri Oxidum Saccharatum; Gossypium Stypticum; Tinctura Ferri Chloridi Ætherea; Tinctura Ferri Citrochloridi.

Uses—This solution is occasionally used as a hemostatic; its principal use, however, is to form, by dilution with alcohol, the well-known tincture of ferric chloride. The dose is from one to two minims (0.06 to 0.12 cc.).

TINCTURA FERRI CHLORIDI. U. S. Tincture of Ferric Chloride

A hydro-alcoholic solution containing about 13 per cent of ferric chloride [$FeCl_3 = 162.22$], corresponding to not less than 4.48 per cent of Fe.

This tincture is made by diluting 350 cc. of solution of ferric chloride with sufficient alcohol to make 1000 cc. The details of the process will be found on page 373. If a brownish-red precipitate of ferric oxychloride takes place upon diluting the solution of ferric chloride, it shows that the solution has not been properly made, and is deficient in free hydrochloric acid.

Description and Physical Properties—A bright, amber-colored liquid, having a slightly ethereal odor, a very astringent, styptic taste, and an acid reaction.

Specific gravity: about 1.00 at 25° C.

Tests for Identity—The Tincture responds to the reactions for ferric iron, page 710, and for chlorides, page 567.

After the Tincture has been exposed for some time to daylight, it yields a greenish or greenish-blue color with potassium ferricyanide T.S. (presence of some *ferrous salt*, due to reduction).

Tests for Purity—Mix 3 cc. of the Tincture with 10 cc. of ferrous sulphate T.S. and carefully superimpose this mixture upon 3 cc. of sulphuric acid contained in a test tube: the zone of contact does not assume a brown or reddish-brown color (*nitrate*).

Assay—Place about 5 cc. of Tincture of Ferric Chloride in a tared weighing bottle, weigh accurately, transfer it to a tall beaker, and evaporate to dryness on a water bath. Add to the residue 2 cc. of hydrochloric acid and 5 cc. of solution of hydrogen dioxide, and again evaporate to dryness. Dissolve this residue in 3 cc. of hydrochloric acid, and transfer to a 250 cc. glass-stoppered flask by means of 25 cc. of distilled water. Add about 1 Gm. of potassium iodide, and allow the mixture to stand for thirty minutes at a temperature of 40° C., the flask being securely stoppered while it is being warmed. Cool the solution, add 100 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

This assay is explained on page 1467.

Preserve in amber-colored, glass-stoppered bottles, protected from light.

Alcohol content, by volume, 58 to 64 per cent.

U. S. P. Preparation—Liquor Ferri et Ammonii Acetatis.

N. F. Preparation—Elixir Chloridorum.

Uses—Tincture of ferric chloride is undoubtedly one of the most important liquid iron preparations that is used; it is an efficient chalybeate tonic and styptic. The dose is from eight to thirty minims (0.5 to 2 cc.), diluted with water; it should be drawn through a glass tube, to prevent injury to the teeth.

FERRI ET AMMONII CITRAS. U. S. Iron and Ammonium Citrate

[**Ferr. et Ammon. Cit.**—Soluble Ferric Citrate, Ammonio-ferric Citrate]

Iron and Ammonium Citrate is ferric citrate rendered more readily soluble by the presence of ammonium citrate and contains not less than 16 per cent and not more than 18 per cent of Fe (55.84).

Preparation—Iron and Ammonium Citrate may be made by the official process of 1890, in which a mixture of 100 cc. of solution of ferric citrate and

40 cc. of ammonia water were evaporated at a temperature not exceeding 60° C. to the consistence of syrup, and spread on glass plates to dry.

Prof. J. U. Lloyd modified this process with advantage by using, instead of ammonia water, a definite quantity of ammonium citrate in solution.

Description and Physical Properties—Thin, transparent, garnet-red scales or granules. It is odorless, and has a saline, mildly ferruginous taste. It is deliquescent in moist air.

Iron and Ammonium Citrate is readily soluble in water. It is insoluble in alcohol.

Tests for Identity—When strongly heated, it chars and finally leaves a residue of ferric oxide.

An aqueous solution of Iron and Ammonium Citrate (1 in 20) is neutral or but slightly acid or alkaline to litmus paper.

Heat about 0.1 Gm. of Iron and Ammonium Citrate with about 5 cc. of potassium hydroxide T.S.: a brownish-red precipitate is produced and ammonia is evolved.

Ammonia T.S. added to an aqueous solution of Iron and Ammonium Citrate (1 in 100) produces no precipitate, but darkens the solution.

Tests for Purity—Remove the iron from 10 cc. of an aqueous solution of Iron and Ammonium Citrate (1 in 10) by boiling it with an excess of potassium hydroxide T.S., filter, and then slightly acidulate 4 cc. of the filtrate with acetic acid: a portion of the cooled filtrate, when mixed with 2 cc. of calcium chloride T.S. and again heated to boiling, gradually deposits a white, crystalline precipitate. The remainder of the filtrate, when acidulated more strongly with acetic acid and allowed to stand for twenty-four hours, does not yield a white, crystalline precipitate (*tartrate*).

An aqueous solution of Iron and Ammonium Citrate (1 in 100) does not yield a blue precipitate with potassium ferrocyanide T.S. unless it is previously acidulated with hydrochloric acid (*ferric citrate*).

Assay—Dissolve about 1 Gm. of Iron and Ammonium Citrate, accurately weighed, in 25 cc. of distilled water and 7 cc. of hydrochloric acid, in a glass-stoppered flask or bottle, add 4 Gm. of potassium iodide, stopper the container securely, and keep it at a temperature of 40° C. for thirty minutes. Then cool, dilute with 100 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

This assay is explained on page 1467.

Preserve in well-closed containers, protected from light

N. F. Preparation—Elixir Carnis et Ferri.

Uses—Iron and ammonium citrate is a useful modification of ferric citrate, the object of adding the ammonia water being to make the salt more quickly soluble. It is a valuable and popular hematinic, free from astringent or irritant properties. The average dose is four grains (0.25 Gm.).

Another commercial form of this salt, known as *iron and ammonium citrate, green* or *green iron citrate* is recognized by the N. N. R. It is largely used in solution in ampuls for intramuscular or subcutaneous injection. It contains the same amount of iron as the official salt but a larger content of ammonium citrate, and is claimed to cause less coagulation of proteins on injection than the official iron and ammonium citrate: Dose hypodermically, from ¼ to 1½ grains (0.015 to 0.1 gm.).

FERRI HYDROXIDUM CUM MAGNESII OXIDO. U. S. Ferric Hydroxide with Magnesium Oxide

[**Ferr. Hydrox. cum Mag. Oxid.**—Arsenic Antidote, Ferric Hydrate with Magnesia]

	Metric	Alternative
Solution of Ferric Sulphate	**40 cc.**	**1 fl. oz. 134 min.**
Magnesium Oxide	**10 Gm.**	**146 gr.**
Water, a sufficient quantity.		

Mix the solution of ferric sulphate with 125 cc. [4 fl. oz.] of water, and keep the liquid in a large, well-stoppered bottle. Rub the magnesium oxide with cold water to a smooth, thin mixture, transfer this to a bottle capable of holding about 1000 cc. [2 pints], fill it with water to about three-fourths of its capacity, and keep it tightly stoppered. When the preparation is needed, shake the magnesium oxide mixture until of a thin, creamy consistence, slowly add to it the diluted solution of ferric sulphate, and shake them together until a uniformly smooth mixture results.

NOTE—In this process the 10 Gm. [146 gr.] of magnesium oxide may be replaced by 300 cc. [9½ fl. oz.] of magnesia magma, diluting it with sufficient water to make the required volume.

The diluted solution of ferric sulphate and the magnesia mixture should be kept on hand in separate bottles ready for immediate use so that the antidote may be quickly prepared.

Uses—Ferric hydroxide is produced when the mixture of magnesium oxide is added to the diluted solution of ferric tersulphate, and, as the magnesium oxide is in excess and acidity thus prevented, no harm can result from not separating the by-products of the reaction. It contains, in addition to the ferric hydroxide, magnesium sulphate and hydroxide. The alternative use of milk of magnesia to replace the magnesium oxide mixture, as suggested by the Pharmacopœial note, is due to the difficulty experienced in keeping the magnesia-water mixture over an extended period without its solidifying. The magnesia magma exhibits no such tendency to become solid.

This preparation is used only as an antidote for arsenic poisoning. Because of the need of promptness in such emergency and as it is only efficient when freshly prepared, the pharmacist should always keep the solutions on hand ready for extemporaneous mixture.

Average dose—Four fluidounces (120 cc.).

SYRUPUS FERRI IODIDI. U. S. Syrup of Ferrous Iodide

Syrup of Ferrous Iodide contains not less than 6.5 Gm. and not more than 7.5 Gm. of FeI_2 in each 100 cc., representing approximately 5 per cent of FeI_2 (309.68), by weight.

This syrup is prepared by forming a solution of ferrous iodide by acting on iron wire with iodine in the presence of water; the details of the process will be found on page 276. The green solution of ferrous iodide, thus prepared, is then protected by the addition of sugar, and the syrup is poured into small, well-stoppered bottles which are to be completely filled. A small amount of diluted hypophosphorous acid is added to aid in its preservation. The syrup is often stored so that it will be exposed to bright daylight, to prevent the separation of free iodine, which is irritating. When an aqueous solution of iodine is exposed to light, colorless hydriodic acid is formed, and this is measurably protected from change through the intervention of the syrup.

Description and Physical Properties—A transparent, pale yellowish-green, syrupy liquid having a sweet, strongly ferruginous taste and a slightly acid reaction.

Specific gravity: about 1.37 at 25° C.

Tests for Identity—Add a few drops of potassium ferricyanide T.S. to 5 cc. of Syrup of Ferrous Iodide: a blue precipitate is produced.

Mix 5 cc. of Syrup of Ferrous Iodide with a few drops of starch T.S. and add three drops of chlorine T.S.: the liquid acquires a deep blue color.

Tests for Purity—No blue color is produced in Syrup of Ferrous Iodide by starch T.S. alone (*free iodine*).

Assay—Place exactly 10 cc. of Syrup of Ferrous Iodide in a flask, dilute it with 30 cc. of distilled water, add 50 cc. of tenth-normal silver nitrate and 5 cc. of nitric acid, and heat on a water bath until the precipitate of silver iodide is yellow. Cool, add 2 cc. of ferric ammonium sulphate T.S., and determine the residual silver nitrate by titration with tenth-normal potassium thiocyanate. Each cc. of tenth-normal silver nitrate corresponds to 0.01548 Gm. of FeI_2.

This assay is explained on page 1462.

Preserve in completely filled, tightly-stoppered bottles.

Uses—It is used as an alterative, the dose being from ten to thirty minims (0.6 to 2 cc.); it should be largely diluted, and drawn through a glass tube to protect the teeth from injury.

FERRI PHOSPHAS SOLUBILIS. U. S. Soluble Ferric Phosphate

[Fer. Phos. Sol.—Ferri Phosphas U.S.P. IX, Ferric Phosphate with Sodium Citrate]

Soluble Ferric Phosphate is ferric phosphate rendered soluble by the presence of sodium citrate and contains not less than 12 per cent of Fe (55.84).

Preparation—No process is given in the Pharmacopœia for this scaled salt; the process of the U. S. P. 1890 is appended.

	Metric	Alternative
Ferric Citrate	**50 Gm.**	10 oz. av.
Sodium Phosphate, uneffloresced	**55 Gm.**	11 oz. av.
Distilled Water	**100 cc.**	19 fl. oz.

Dissolve the ferric citrate in the distilled water by heating on a water bath. To this solution add the sodium phosphate, and stir constantly until it is dissolved. Evaporate the solution, on a water bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that when dry, the salt may be obtained in scales.

This scaled salt is very different from the insoluble, slate-colored powder of iron phosphate formerly official. It is not a definite chemical compound, but is sometimes termed sodio-ferric citro-phosphate. It resembles the official ferric pyrophosphate in its physical appearance.

Description and Physical Properties—Thin, bright green, transparent scales or granules. It is without odor, and has an acidulous, slightly saline taste. The salt is stable in dry air when protected from light, but when unprotected soon becomes discolored.

Soluble Ferric Phosphate is freely soluble in water. It is insoluble in alcohol.

Tests for Identity—An aqueous solution of Soluble Ferric Phosphate (1 in 10) is slightly acid to litmus paper.

The addition of an excess of ammonia T.S. to an aqueous solution of Soluble Ferric Phosphate produces a reddish-brown color but no precipitate.

Boil about 0.1 Gm. of Soluble Ferric Phosphate with 5 cc. of sodium hydroxide T.S.: a brownish-red precipitate is produced without the evolution of ammonia (*ammonium salts*).

Remove the iron from 10 cc. of an aqueous solution of Soluble Ferric Phosphate (1 in 10) by boiling it with an excess of sodium hydroxide T.S., filter out the precipitate, and strongly acidulate the filtrate with hydrochloric acid: a cooled portion of this liquid mixed with an equal volume of magnesia mixture T.S. and treated with a slight excess of ammonia T.S. produces an abundant white, crystalline precipitate. This precipitate after washing turns yellow when treated with a few drops of silver nitrate T.S. (*distinction from pyrophosphate*).

Assay—Dissolve about 1 Gm. of Soluble Ferric Phosphate, accurately weighed, in 25 cc. of distilled water and 15 cc. of hydrochloric acid, in a glass-stoppered bottle, then add 3 Gm. of potassium iodide, securely stopper the bottle, and keep it at a temperature of 40° C. for thirty minutes. Then cool, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

This assay is explained on page 1467.

Preserve in well-closed containers, protected from light.

N. F. Preparations—Elixir Cinchonæ Alkaloidorum et Ferri; Elixir Gentianæ et Ferri Phosphatis; Liquor Phosphatum Compositum; Syrupus Ferri, Quininæ et Strychninæ Phosphatum.

Uses—This is a non-astringent ferruginous tonic frequently used in anemia. It is given in doses of four to ten grains (0.25 to 0.65 Gm.).

FERRI SULPHAS. U. S. Ferrous Sulphate

[Ferr. Sulph.—Iron Protosulphate]

Ferrous Sulphate contains not less than 54.36 and not more than 57.07 per cent of anhydrous ferrous sulphate, corresponding to about 99.5 per cent of the crystallized salt [$FeSO_4.7H_2O = 278.01$].

Preparation—This salt is never made by the pharmacist, because the commercial article is sold at a very low price. The following is a former official British process:

Take of iron wire, 4 oz. av.; sulphuric acid, 4 fl. oz. [Imperial measure]; distilled water, 1½ pints [Imperial measure]. Pour the water on the iron placed in a porcelain dish, add the sulphuric acid, and, when the evolution of gas has nearly ceased, boil for ten minutes. Filter promptly through paper, and, after the lapse of twenty-four hours, separate the crystals which have been deposited from the solution. Let these be dried on filter paper placed on porous bricks, and be preserved in a stoppered bottle.

The salt is a by-product in the manufacture of hydrogen, the following being the reaction:

$$\underset{\text{iron}}{Fe_2} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{2H_2SO_4} = \underset{\substack{\text{ferrous}\\\text{sulphate}}}{2FeSO_4} + \underset{\text{hydrogen}}{4H}$$

Description and Physical Properties—Pale, bluish-green, monoclinic prisms. It is odorless and has a saline, styptic taste. The salt is efflorescent in dry air, but on exposure to moist air, the crystals rapidly oxidize and become coated with brownish-yellow, basic ferric sulphate. When it has thus deteriorated, the salt must not be used for any official or medicinal purpose.

One Gm. of Ferrous Sulphate is soluble in 1.4 cc. of water at 25° C. and in 0.4 cc. of boiling water. It is insoluble in alcohol.

When slowly heated to 115° C., the crystals disintegrate and the salt loses the greater part of its water of crystallization.

Tests for Identity—An aqueous solution of the salt (1 in 20) is acid to litmus paper.

Ferrous Sulphate responds to the reactions for ferrous salts, page 710, and for sulphates, page 581.

Tests for Purity—Dissolve 1 Gm. of the salt in about 50 cc. of distilled water containing 1 cc. of diluted sulphuric acid, heat the solution to boiling, oxidize it with nitric acid, mix it with a slight excess of ammonia T.S., and filter: the filtrate is colorless and after acidulating with hydrochloric acid meets the requirements of the test for *heavy metals*, page 1519.

Agitate 1 Gm. of Ferrous Sulphate, in small fragments, during four or five minutes with 10 cc. of alcohol, and filter the mixture: the filtrate does not immediately redden moistened blue litmus paper (*free acid*).

Assay—Dissolve about 1 Gm. of Ferrous Sulphate, accurately weighed, in 25 cc. of diluted sulphuric acid, and titrate with tenth-normal potassium permanganate until a permanent pink color is produced. Each cc. of tenth-normal potassium permanganate corresponds to 0.01519 Gm. of $FeSO_4$.

This assay is explained on page 1474.

Preserve in well-closed containers.

U. S. P. Preparations—Ferri Carbonas Saccharatus; Ferri Sulphas Exsiccatus; Ferri Sulphas Granulatus; Liquor Ferri Tersulphatis; Massa Ferri Carbonatis.

N. F. Preparation—Liquor Ferri Subsulphatis.

Uses—This is a very astringent iron salt. When used internally the exsiccated or granulated salt is preferred. The impure ferrous sulphate, called *copperas*,[1] is used as a disinfectant. The name, *green vitriol* is also applied to this salt. The dose of the sulphate is one to three grains (0.065 to 0.2 Gm.).

FERRI SULPHAS EXSICCATUS. U. S. Exsiccated Ferrous Sulphate

[**Ferr. Sulph. Exsic.**—Dried Ferrous Sulphate]

Exsiccated Ferrous Sulphate contains the equivalent of not less than 80 per cent of anhydrous ferrous sulphate [$FeSO_4 = 151.90$].

	Metric	Alternative
Ferrous Sulphate, in coarse powder.....	**100 Gm.**	25 oz. av.

Allow the salt to effloresce at a temperature of about 40° C. in dry air, and then heat it in a tared porcelain dish on a water bath, constantly stirring, until the product weighs from 64 to 65 Gm. [16 oz. av.]. Reduce the residue to a fine powder, and transfer it at once to dry bottles, which should be stoppered immediately.

[1] This unfortunate synonym, "*copperas*," has led to a great many errors, through the impression that this salt must contain copper. It is often confounded with the poisonous copper sulphate, or blue vitriol, and they have been substituted for each other.

This process does not deprive the ferrous sulphate of all of its water of crystallization, about 15 per cent being retained. One hundred parts of crystallized sulphate yield about 64 per cent of the exsiccated salt.

The reason for exposing it first to a temperature of 40° C. is that if a higher temperature is applied at the start, the salt melts in its water of crystallization and subsequent drying is much more difficult.

Description and Physical Properties —A grayish-white powder, slowly soluble in water.

Tests for Identity and Purity—A solution of the salt (1 in 20) in recently boiled distilled water is not more than slightly turbid, and when taken in proportionate amount, conforms to the reactions and tests under *Ferri Sulphas*, except the test for free acid.

Assay —Dissolve about 0.8 Gm. of Exsiccated Ferrous Sulphate, accurately weighed, in 25 cc. of diluted sulphuric acid, and titrate with tenth-normal potassium permanganate until a permanent pink color is produced. Each cc. of tenth-normal potassium permanganate corresponds to 0.01519 Gm. of $FeSO_4$.

This assay is explained on page 1474.

Preserve in tightly-stoppered bottles.

N. F. Preparations—Pilulæ Aloes et Ferri; Pilulæ Ferri, Quininæ, Aloes et Nucis Vomicæ.

Uses—Exsiccated ferrous sulphate is a grayish-white powder, and is principally used in making pills, the crystallized sulphate being unfitted for the purpose on account of the large proportion of water that it contains. Five grains of the crystals are represented by three grains of the exsiccated sulphate. It must be kept in tightly-closed containers to prevent the absorption of moisture. The dose is one grain (0.065 Gm.).

FERRI SULPHAS GRANULATUS. U. S. Granulated Ferrous Sulphate

[**Ferr. Sulph. Gran.**—Precipitated Ferrous Sulphate]

	Metric	Alternative
Ferrous Sulphate	**100 Gm.**	4 oz. av.
Distilled Water	**100 cc.**	4 fl. oz.
Diluted Sulphuric Acid	**5 cc.**	1½ fl. dr.
Alcohol	**25 cc.**	1 fl. oz.

Add the diluted sulphuric acid to the distilled water, heat to boiling, dissolve the ferrous sulphate in the liquid, and filter the solution while hot. Evaporate the solution immediately in a tared porcelain dish on a sand bath until it weighs 150 Gm. [6 oz. av.], and cool it quickly with constant stirring. Transfer the product to a glass funnel fitted with a pledget of purified cotton, and when it has thoroughly drained pour the alcohol upon it. When this has also drained, spread the crystalline powder on bibulous paper, dry it quickly at room temperature, and transfer it at once to dry bottles, which should be stoppered immediately.

Description and Physical Properties—A pale, bluish-green, crystalline powder, which meets the requirements of the tests for identity and purity and the assay under *Ferri Sulphas*.

Preserve in tightly-stoppered bottles.

U. S. P. Preparation—Pilulæ Ferri Carbonatis.

Ferrous sulphate is insoluble in alcohol; hence, if a strong aqueous solution is poured into alcohol, it is precipitated in the form of a granular crystalline powder, and this method was used in the U. S. P. 1880 for preparing this salt. The process of subsequent Pharmacopœias differed in that the sulphate is not precipitated but granulated by evaporation and cooling, with constant stirring, and subsequently washing with alcohol to free it from impurities and to facilitate the drying of the granules.

Uses—Granulated ferrous sulphate should be used in preference to the large crystals at the prescription counter, the soluble impurities being washed out by the alcohol. It is much less liable to oxidation and change than the ordinary crystallized sulphate. The dose is about one and one-half grains (0.1 Gm.).

LIQUOR FERRI ET AMMONII ACETATIS. U.S. Solution of Iron and Ammonium Acetate

[**Liq. Ferr. et Ammon. Acet.**—BASHAM'S MIXTURE]

Solution of Iron and Ammonium Acetate contains, in each 100 cc., ammonium acetate corresponding to not less than 0.6 Gm. and not more than 0.8 Gm. of NH_3(13.03), and not less than 0.16 Gm. and not more than 0.20 Gm. of Fe (55.84).

Caution—This preparation must not be dispensed unless it has been recently prepared.

	Metric	Alternative
Tincture of Ferric Chloride	**40 cc.**	4 fl. dr.
Diluted Acetic Acid	**60 cc.**	6 fl. dr.
Solution of Ammonium Acetate	**500 cc.**	6¼ fl. oz.
Aromatic Elixir	**120 cc.**	1½ fl. oz.
Glycerin	**120 cc.**	1½ fl. oz.
Distilled Water, a sufficient quantity, To make	**1000 cc.**	12½ fl. oz.

To the solution of ammonium acetate (which must be slightly acid) add, successively, the diluted acetic acid, the tincture of ferric chloride, the aromatic elixir, and the glycerin, and lastly enough distilled water to make the product measure 1000 cc. [12½ fl. oz.].

While an excess of acid is necessary to avoid the precipitation of basic ferric acetate, yet care should be taken to avoid a large excess, since extreme acidity makes the solution unnecessarily disagreeable.

This solution is not intended to be permanent, and in time will decompose; besides, the freshly prepared solution, containing dissolved carbonic acid, is more agreeable to the taste than one which is "flat", hence the directions to prepare as needed.

Uses—This is a mild ferruginous solution, used especially in kidney diseases. The dose is four fluidrachms (15 cc.).

Description and Physical Properties—A clear, reddish-brown liquid, having an aromatic odor. Specific gravity: about 1.039 at 25° C.

Tests for Identity—The solution is acid to litmus paper.

The Solution yields a blue precipitate with potassium ferrocyanide T.S. No precipitate is produced upon the addition of ammonia T.S.

When Solution of Iron and Ammonium Acetate is heated with sodium hydroxide T.S., ammonia is evolved.

Add 1 cc. each of sulphuric acid and alcohol to 5 cc. of the Solution and boil the mixture: ethyl acetate is formed, recognizable by its odor.

Assay for Ammonia—Transfer to a distilling flask with the aid of distilled water exactly 25 cc. of Solution of Iron and Ammonium Acetate, and add sufficient distilled water to make about 200 cc. Add 20 cc. of 20 per cent sodium hydroxide solution, and distil about 150 cc., receiving the distillate in 40 cc. of half-normal sulphuric acid. Titrate the excess of acid with half-normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of half-normal sulphuric acid corresponds to 0.008520 Gm. of NH_3.

This assay is explained on page 1457.

Assay for Iron—Transfer to a dish with the aid of a little distilled water exactly 25 cc. of Solution of Iron and Ammonium Acetate. Evaporate to dryness and gently ignite. Heat the residue with 10 cc. of hydrochloric acid, and, when all of the iron has dissolved, add 10 cc. of solution of hydrogen dioxide, and evaporate to dryness on a water bath. Add 5 cc. of hydrochloric acid, warm until all is dissolved, and transfer the solution to a glass-stoppered flask with the aid of about 30 cc. of distilled water. Add about 2 Gm. of potassium iodide, allow to stand for thirty minutes at about 40° C., cool, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

This assay is explained on page 1467.

LIQUOR FERRI TERSULPHATIS. U.S. Solution of Ferric Sulphate

[Liq. Ferr. Tersulph.—Solution of Iron Tersulphate]

An aqueous solution containing normal ferric sulphate [$Fe_2(SO_4)_3$ = 151.90], corresponding to not less than 9.5 per cent and not more than 10.5 per cent of Fe (55.84).

	Metric	Alternative
Ferrous Sulphate	**500 Gm.**	12 oz. av. 19 gr.
Sulphuric Acid	**96 Gm.**	1 fl. oz. 103 min.
Nitric Acid,		
Distilled Water, each, a sufficient quantity,		
To make	**1000 Gm.**	1 pint

Add the sulphuric acid to about 250 cc. [3¾ fl. oz.] of distilled water in a tared, capacious porcelain dish, heat the mixture to nearly 100° C., then add 56 Gm. [7 fl. dr.] of nitric acid, and mix well. Divide the ferrous sulphate, coarsely powdered, into four approximately equal portions, and add these portions one at a time to the hot liquid, stirring after each addition until effervescence ceases. When all of the ferrous sulphate is dissolved, if the solution has acquired a black color, add nitric acid, a few drops at a time, heating and stirring until red fumes cease to be evolved, and the solution assumes a clear reddish-brown color; then boil the liquid until it is free from nitric acid, as indicated by the test given below. During the heating add distilled water from time to time to maintain about the original volume. Lastly, add enough distilled water to make the product weigh 1000 Gm. [or measure 1 pint]. Filter, if necessary.

This solution differs from the solution of ferric subsulphate merely in containing a larger proportion of sulphuric acid. It has the sp. gr. 1.432, and is a solution of the *true* tersulphate, $Fe_2(SO_4)_3$, or normal ferric sulphate. The reaction for solution of ferric sulphate is shown by the following equation:

$$\underset{\text{ferrous sulphate}}{6FeSO_4} + \underset{\text{sulphuric acid}}{3H_2SO_4} + \underset{\text{nitric acid}}{2HNO_3} = \underset{\text{ferric sulphate}}{3Fe_2(SO_4)_3} + \underset{\text{nitrogen dioxide}}{2NO} + \underset{\text{water}}{4H_2O}$$

Description and Physical Properties—A reddish-brown liquid, almost odorless, having an acid, strongly styptic taste, and an acid reaction.

Solution of Ferric Sulphate is miscible with water and alcohol.

Specific gravity: about 1.432 at 25° C.

Tests for Identity—Solution of Ferric Sulphate responds to the reactions for ferric iron, page 710, and for sulphates, page 581.

Tests for Purity—Mix 1 cc. of the Solution with 10 cc. of ferrous sulphate T.S. and superimpose it upon 5 cc. of sulphuric acid contained in a test tube: the line of contact does not assume a brown or brownish-black color (*nitrate*).

Add a few drops of freshly prepared potassium ferricyanide T.S. to 2 cc. of an aqueous dilution of the Solution (1 in 20): a brown color is produced without a tinge of green or greenish-blue (*ferrous salt*).

Assay—Transfer about 1.5 Gm. of Solution of Ferric Sulphate to a tared flask, stopper and weigh accurately, then add 5 cc. of hydrochloric acid, 25 cc. of distilled water, and 2 Gm. of potassium iodide, securely stopper the flask, and allow the mixture to stand for thirty minutes at a temperature of 40° C. Cool the liquid, dilute it with 50 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

This assay is explained on page 1467.

U. S. P. Preparation—Ferri Hydroxidum cum Magnesii Oxido.

N. F. Preparation—Liquor Ferri Citratis.

Uses—This solution is largely used in pharmacy for preparing ferric hydroxide by precipitation with ammonia water (see p. 732). From this many of the iron salts and solutions are made. It is not used medicinally to any extent, the solution of the subsulphate being preferred.

FERRUM ALBUMINATUM. N. F. Albuminized Iron

[Ferr. Albumin.—Iron Albuminate]

Albuminized Iron is a compound of iron oxide and albumin, rendered soluble by the presence of sodium citrate. It contains not less than 17 per cent and not more than 19 per cent of Fe.

Description and Physical Properties—Reddish brown, lustrous granules, or a brown powder. It is odorless, or has not more than a slight odor.

Albuminized Iron is freely soluble in water yielding dark solutions. It is almost insoluble in alcohol.

Tests for Identity—The addition of acids to an aqueous solution of Albuminized Iron produces a precipitate which dissolves by warming with an excess of hydrochloric acid. The resulting solution yields the reactions characteristic of ferric iron.

An aqueous solution of Albuminized Iron (1 in 20) is neutral or slightly alkaline to litmus paper.

An aqueous solution (1 in 50) yields no blue color upon the addition of potassium ferrocyanide T.S. (absence of *ionic iron*).

Tests for Purity—Dissolve 1 Gm. of Albuminized Iron in 50 cc. of distilled water. Render the solution slightly alkaline, if necessary, by the addition of sodium hydroxide T.S., and precipitate the iron from the solution with hydrogen sulphide. Filter, add to the filtrate 5 cc. of diluted hydrochloric acid and evaporate almost to dryness on the water bath. Dissolve the residue in 10 cc. of distilled water, and to 5 cc. of the solution, rendered slightly alkaline with sodium hydroxide, add 2 cc. of alkaline cupric tartrate solution and heat. No red precipitate is produced (*sugar*).

Assay—Weigh accurately about 0.5 Gm. of Albuminized Iron and ignite it in a crucible to destroy the organic matter. Allow to cool, transfer the residue completely into a beaker, add 10 cc. of hydrochloric acid, heat until all the iron is dissolved, then add 10 cc. of hydrogen dioxide T.S., and evaporate almost to dryness on the water bath. Dissolve the residue by warming with 5 cc. of hydrochloric acid and 10 cc. of water and transfer the solution completely into a glass-stoppered flask, filtering if necessary, and washing the residue, and filter with small quantities of hot water until free from iron. Now add to the solution 3 Gm. of potassium iodide, allow to stand for one-half hour at about 40° C., cool and titrate the liberated iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of iron (Fe).

This assay is explained on page 1467.

N. F. Preparation—Liquor Ferri Albuminati.

Uses—Albuminized iron was added to the N. F. for the preparation of the solution (see page 724). It is a blood tonic in doses of eight grains (0.5 Gm.).

LIQUOR FERRI ALBUMINATI. N. F. Solution of Albuminized Iron

[Liq. Ferr. Albumin.—Solution of Iron Albuminate]

	Metric	Alternative
Albuminized Iron	**50 Gm.**	1 oz. av. 293 gr.
Cinnamon Water	**200 cc.**	6 fl. oz. 192 min.
Aromatic Elixir	**400 cc.**	12 fl. oz. 384 min.
Alcohol	**120 cc.**	3 fl. oz. 403 min.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve the albuminized iron in the cinnamon water and 150 cc. [4 fl. oz. 384 min.] of distilled water, add the aromatic elixir, the alcohol and sufficient distilled water to make the product measure 1000 cc. [2 pints]. Allow it to stand twelve hours, and filter.

In the N. F. IV this solution was prepared by mixing 180 cc. of fresh egg albumin with 130 Gm. of freshly made solution of ferric oxychloride, with constant stirring, and allowing the mixture to stand for two hours. Then a solution of 12.5 Gm. of sodium citrate in 100 cc. of water was added, followed by the amounts of alcohol and aromatic elixir given above and then distilled water to make 1000 cc.

Solution of Albuminized Iron is a clear, yellowish brown liquid, having an aromatic odor, and an aromatic taste.

Specific gravity: about 1.044 at 25° C.

Evaporate 10 cc. of the Solution on a water bath; it leaves not more than 1.661 Gm. of residue. Incinerate the residue from 10 cc. of the Solution; it leaves not more than 0.0625 Gm. of ash.

Dilute 5 cc. of the solution with 5 cc. of distilled water and add 1 cc. of hydrochloric acid and a few drops of potassium sulphocyanate T.S.: a blood red color is formed (*ferric iron*).

Preserve the Solution in dark amber-colored bottles.

Uses—It is used as a blood tonic in a dose of from one to two fluidrachms (4 to 8 cc.).

LIQUOR FERRI CITRATIS. N.F. Solution of Ferric Citrate

[Liq. Ferr. Cit.]

An aqueous solution containing ferric citrate corresponding to not less than 8.75 Gm. of Fe in each 100 cc.

	Metric	Alternative
Solution of Ferric Sulphate	**730 cc.**	23 fl. oz. 173 min.
Citric Acid	**375 Gm.**	12 oz. av. 226 gr.
Ammonia Water	**1100 cc.**	35 fl. oz. 96 min.
Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Mix the ammonia water with 3000 cc. [6 pints] of cold water, and the solution of ferric sulphate with 10,000 cc. [20 pints] of cold water. Add the latter solution slowly to the diluted ammonia water, stirring constantly. Pour the mixture upon a wet muslin strainer, and allow the liquid to run off and the precipitate to drain. Then remove the moist mass from the strainer, mix it well with 6000 cc. [12 pints] of cold water, again pour it on the strainer, and let it drain. Repeat this washing with several successive portions of cold water, in the same manner, until the washings cease to produce more than a faint cloudiness with barium chloride T.S. Then allow the precipitate to drain completely, transfer it to a porcelain dish, add the citric acid, and heat the mixture on a water bath to 60° C., stirring constantly until the magma is dissolved. Lastly, filter the liquid, and evaporate it, at the above-mentioned temperature, until it measures 1000 cc. [2 pints].

Solution of Ferric Citrate is a dark reddish brown liquid, having a characteristic odor suggestive of caramel, and a saline, ferruginous and slightly astringent taste. It is acid to litmus paper.

Specific gravity: about 1.262 at 25° C.

Heat the Solution of Ferric Citrate with potassium hydroxide T.S.: it yields a brownish-red precipitate, without evolving ammonia (*difference from solution of Iron and Ammonium citrate*).

Precipitate the iron from Solution of Ferric Citrate by boiling with an excess of potassium hydroxide T.S., and acidulate the filtrate slightly with acetic acid: a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, will gradually afford a white, crystalline precipitate.

Another portion of the acidulated and cooled liquid, when allowed to stand for twenty-four hours, does not deposit a white, crystalline precipitate (*tartrates*).

Assay—Add 2 cc. of the Solution, accurately measured, to 2 cc. of hydrochloric acid and 10 cc. of solution of hydrogen dioxide and evaporate to dryness. Dissolve the residue in 2 cc. of hydrochloric acid and 40 cc. of distilled water, transfer to a flask, add 2 Gm. of potassium iodide, stopper the flask and warm the mixture to 40° C. for thirty minutes. Then cool and titrate the liberated iodine with tenth-normal sodium thiosulphate.

Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe. Each cc. of Solution of Ferric Citrate corresponds to not less than 15.7 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1467.

Preserve the Solution in dark amber-colored bottles.

Uses—It is used as an iron tonic in doses of ten minims (0.6 cc.).

FERRI GLYCEROPHOSPHAS. N.F. Ferric Glycerophosphate

[Ferr. Glycerophos.—Ferric Glycerinophosphate]

Ferric Glycerophosphate contains a variable quantity of $Fe_2(C_3H_7O_6P)_3$(622.02) corresponding to not less than 14 per cent and not more than 16 per cent of Fe.

Preparation—It may be prepared by adding solution of ferric sulphate to solution of barium glycerophosphate, filtering out the barium sulphate and evaporating the filtrate or by dissolving ferric hydroxide in glycerophosphoric acid and evaporating the solution.

$$\underset{\text{ferric sulphate}}{Fe_2(SO_4)_3} + \underset{\text{barium glycerophosphate}}{3Ba(C_3H_5(OH)_2PO_4)} = \underset{\text{barium sulphate}}{3BaSO_4} + \underset{\text{ferric glycerophosphate}}{Fe_2(C_3H_5(OH)_2PO_4)_3}$$

Description and Physical Properties—Ferric Glycerophosphate occurs as yellowish-green, transparent, amorphous scales or as a greenish-yellow powder; odorless and nearly tasteless.

One Gm. dissolves slowly in about 2 cc. of water at 25° C.; insoluble in alcohol. An aqueous solution is acid to litmus and becomes turbid when heated.

Tests for Identity—An aqueous solution of the salt (1 in 20) is colored dark blue by potassium ferrocyanide T.S.; on the subsequent addition of hydrochloric acid a dark blue precipitate is produced.

Heat a powdered mixture of about 0.1 Gm. of the salt with about 0.5 Gm. of potassium bisulphate; the pungent vapors of acrolein are evolved.

Tests for Purity—Not more than a slight yellow turbidity is produced at once on mixing 5 cc. of an aqueous solution of the salt (1 in 50) with 10 cc. of ammonium molybdate T.S. (*phosphate*), but on standing or on warming, a yellow precipitate is formed.

An aqueous solution of the salt (1 in 50), acidulated with hydrochloric acid, does not become more than slightly turbid on the addition of barium chloride T.S. (*sulphate*).

Another portion of this aqueous solution, acidulated with nitric acid, does not become more than slightly turbid on the addition of silver nitrate T.S. (*chloride*).

Assay—Dissolve about 0.5 Gm. of Ferric Glycerophosphate, accurately weighed, in 50 cc. of distilled water, in a 100 cc. glass-stoppered flask, add 5 cc. of hydrochloric acid and about 3 Gm. of potassium iodide. Warm to 40° C., and allow the mixture to stand one-half hour at this temperature in the stoppered flask, cool, and then titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator.

Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe. Each Gm. of Ferric Glycerophosphate corresponds to not less than 25.07 cc. nor more than 28.65 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1467.

Preserve it in well-closed containers, protected from light.

N. F. Preparation—Elixir Glycerophosphatum Compositum.

Uses—It is used as a tonic and alterative, chiefly in the compound elixir. The dose is three grains (0.2 Gm.).

FERRIC HYPOPHOSPHIS. N. F. Ferric Hypophosphite

[Ferr. Hypophos.]

Ferric Hypophosphite contains not less than 98 per cent of $Fe(PH_2O_2)_3$ (251.01), corresponding to not less than 21.8 per cent of Fe.

Preparation—This is among the hypophosphites brought into notice in consequence of their recommendation by Doctor Churchill in the treatment of phthisis in which they were thought to be useful by the introduction of phosphorus into the system. This particular salt may be considered preferable to others when a marked condition of anemia indicates a deficiency of iron in the tissues. It may be made by the action of hypophosphorous acid on ferrous carbonate; but, as some difficulty has been found in obtaining this acid perfectly pure, preference has been given to the plan of double decomposition. This salt may be made by causing ferrous sulphate and calcium hypophosphite to react on each other in molecular proportions represented by 480 grains of crystallized ferrous sulphate and 299 grains of calcium hypophosphite—in the latter an allowance of 2 per cent being made for impurities ordinarily found in that salt. These quantities will yield about 320 grains of ferric hypophosphite and the reaction will be represented by the following formula:

$$\underset{\text{calcium hypophosphite}}{Ca(PH_2O_2)_2} + \underset{\text{ferrous sulphate}}{FeSO_4} = \underset{\text{calcium sulphate}}{CaSO_4} + \underset{\text{ferrous hypophosphite}}{Fe(H_2PO_2)_2}$$

Calcium sulphate is precipitated, and ferrous hypophosphite is held in solution. In this condition the salt is a ferrous compound, but on evaporation the ferrous salt becomes ferric, and acquires the properties detailed in the National Formulary.

Description and Physical Properties—Ferric Hypophosphite occurs as a white, or grayish-white powder, odorless and nearly tasteless; permanent in the air.

One Gm. dissolves in 2300 cc. of water at 25° C. and in 1200 cc. of boiling water; more readily soluble in the presence of hypophosphorous acid or in a warm, concentrated solution of an alkali citrate, forming with the latter a green solution.

Tests for Identity—When strongly heated in a dry test tube, the salt evolves spontaneously inflammable hydrogen phosphide gas, and finally leaves a residue of ferric pyrophosphate.

Ferric Hypophosphite is readily oxidized by nitric acid or other oxidizing agents.

Tests for Purity—Add 15 cc. of acetic acid to 1 Gm. of the salt; no effervescence occurs (*carbonate*). Heat the mixture to boiling and filter; the filtrate responds to the following tests.

Add to a portion of the filtrate a few drops of silver nitrate T.S. and warm; a brown to black coloration or precipitate is produced. To another portion of the filtrate add, drop by drop, an excess of mercuric chloride T.S.; a white precipitate of mercurous chloride is formed upon gently heating.

Another 5 cc. portion of the filtrate shows no turbidity with ammonium oxalate T.S. (*calcium*).

Dissolve 1 Gm. of the salt in 20 cc. of diluted hydrochloric acid, with the aid of heat, and add 1 cc. of barium chloride T.S.; not more than a slight turbidity is produced (*sulphate*).

Boil 0.5 Gm. of the salt with 10 cc. of sodium hydroxide T.S.: a reddish-brown precipitate is produced. Filter this mixture, slightly acidulate the filtrate with hydrochloric acid, add magnesia mixture T.S., and then an excess of ammonia water; no crystalline precipitate is produced (*phosphate*).

Dissolve 1 Gm. of the salt in about 25 cc. of boiling distilled water by the aid of sufficient hydrochloric acid, added, drop by drop, then add 2 cc. of nitric acid, boil and add a slight excess of ammonia water; the filtrate is colorless, and after acidulating with hydrochloric acid does not respond to the test for heavy metals (see page 1519).

Assay—To 1 Gm. of Ferric Hypophosphite accurately weighed, add 10 cc. of nitrohydrochloric acid and evaporate to dryness on a water bath. Dissolve the residue in 25 cc. of distilled

water and 10 cc. of hydrochloric acid, transfer the solution to a glass-stoppered flask, add 3 Gm. of potassium iodide, keep it at 40° C. for thirty minutes, cool and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator.

Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe, and 0.025101 Gm. of $Fe(PH_2O_2)_3$. Each Gm. of Ferric Hypophosphite requires not less than 39.04 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1467.

Preserve it in well-closed containers.

N. F. Preparations—Liquor Hypophosphitum Compositus, Syrupus Hypophosphitum Compositus.

Uses—Ferric hypophosphite is rarely used except as an ingredient of the syrup or elixir of hypophosphites. It has the hematinic action of the iron salts in general. The dose is from three to ten grains (0.2 to 0.6 Gm.).

FERRI LACTAS. N.F. Ferrous Lactate

[**Ferr. Lact.**—IRON LACTATE]

Ferrous Lactate contains not less than 97 per cent of Fe $(C_3H_5O_3)_2.3H_2O$ (288.00).

Preparation—It may be made by digesting iron filings with lactic acid until a neutral solution is produced, filtering and crystallizing.

Description and Physical Properties—Ferrous Lactate occurs as a greenish-white, crystalline powder, or in crystalline masses, having a slight, characteristic odor, and a mild, sweet and ferruginous taste.

One Gm. dissolves slowly but almost completely in 40 cc. of water at 25° C., and in 12 cc. of boiling water; freely soluble in solutions of the alkali citrates yielding a green-colored solution; almost insoluble in alcohol.

Tests for Identity—When strongly heated, the salt froths, gives out dense, white, acrid fumes, then chars and finally leaves a brownish-red residue.

An aqueous solution of the salt is greenish-yellow, slightly acid to litmus and separate portions give a deep blue precipitate with potassium ferricyanide T.S., and a light blue precipitate with potassium ferrocyanide T.S.

Tests for Purity—Separate portions of an aqueous solution of the salt (1 in 20), acidulated with nitric acid, do not give more than a slight opalescence with barium chloride T.S. (*sulphate*), or with silver nitrate T.S. (*chloride*).

Mix 25 cc. of an aqueous solution of the salt (1 in 50) with 5 cc. of diluted sulphuric acid, boil the mixture for a few minutes, then precipitate the iron by an excess of sodium hydroxide T.S., and filter; the filtrate, mixed with a few drops of alkaline cupric tartrate solution and heated to boiling, does not give a red precipitate (*sugar*).

A portion of the salt triturated with sulphuric acid does not develop an offensive odor (*butyric acid*); this mixture, after standing for five minutes, does not assume a brown color (*readily carbonizable impurities*).

Ignite 1 Gm. of the salt; the residue is not alkaline to moistened litmus paper, and does not contain anything soluble in water.

Assay—Dissolve, in a glass-stoppered flask, about 0.5 Gm. of Ferrous Lactate, accurately weighed, in 15 cc. of solution of hydrogen dioxide and 5 cc. of hydrochloric acid, and evaporate this solution on a water bath to 5 cc. Add 3 cc. of hydrochloric acid, boil the mixture for two minutes, cool to 40° C. and add 25 cc. of distilled water and 1 Gm. of potassium iodide. Allow this mixture to stand for one-half hour at 40° C., cool and then titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator.

Each cc. of tenth-normal sodium thiosulphate corresponds to 0.0288 Gm. of $Fe(C_3H_5O_3)_2.3H_2O$. Each Gm. of Ferrous Lactate requires not less than 33.7 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1467.

Preserve it in well-closed containers.

N. F. Preparation—Syrupus Calcii Lactophosphatis et Ferri.

Uses—Used much like other iron tonics; it is especially known for its absence of marked astringency. Given in doses of two to ten grains (0.13 to 0.6 Gm.).

FERRI OXIDUM SACCHARATUM. N.F. Saccharated Ferric Oxide

[**Ferr. Oxid. Sacch.**—SOLUBLE FERRIC OXIDE, FERRUM OXYDATUM SACCHARATUM, EISENZUCKER]

Saccharated Ferric Oxide contains the equivalent of not less than 2.8 per cent of Fe.

	Metric	Alternative
Solution of Ferric Chloride	**300 Gm.**	2 oz. av. 175 gr.
Monohydrated Sodium Carbonate	**112 Gm.**	392 gr.
Water	**3000 cc.**	1½ pints
Sodium Hydroxide,		
Sucrose, in powder, each, a sufficient quantity,		
To make	**1000 Gm.**	8 oz. av.

Dilute the solution of ferric chloride with 1500 cc. [12 fl. oz.] of water and gradually add, with constant stirring, a solution of the monohydrated sodium carbonate in the remainder of the water. Wash the precipitate with water by decantation or siphoning until the washings, when diluted with five volumes of water, give only a slight opalescence with silver nitrate T.S. Then collect the precipitate on a cloth strainer, press it out, transfer the magma to a porcelain dish on a water bath, add 500 Gm. [4 oz. av.] of sucrose and a sufficient quantity (not more than 50 Gm. [175 gr.]) of a 15 per cent solution of sodium hydroxide to produce a clear solution. Evaporate the mixture to dryness on a water bath and if necessary add sufficient sucrose to make the product weigh 1000 Gm. [8 oz. av.].

An aqueous solution (1 in 20) yields no blue color with potassium ferrocyanide T.S.

Assay—Dissolve about 8 Gm. of Saccharated Ferric Oxide, accurately weighed, in 50 cc. of diluted hydrochloric acid; add 4 Gm. of potassium iodide and allow the solution to stand for thirty minutes at a temperature of 40° C. Cool the solution, dilute it with 100 cc. of distilled water and titrate the liberated iodine with tenth-normal sodium thiosulphate using starch T.S. as indicator.

Each cc. of tenth-normal sodium thiosulphate used corresponds to 0.005584 Gm. of Fe. Each Gm. of Saccharated Ferric Oxide corresponds to not less than 5.01 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1467.

N. F. Preparation—Syrupus Ferri Saccharati Solubilis.

Uses—This is a preparation of the German and Austrian Pharmacopœias and is a mild chalybeate. The dose is ten to thirty grains (0.6 to 2 Gm.).

FERRI PYROPHOSPHAS SOLUBILIS. N. F. Soluble Ferric Pyrophosphate [Ferr. Pyrophos. Sol.]

Soluble Ferric Pyrophosphate, rendered soluble by the presence of sodium citrate, and corresponding to not less than 10 per cent of Fe.

Preparation—It may be prepared by dissolving sodium pyrophosphate in a strong solution of an equal weight of ferric citrate, evaporating at not over 60° C. to syrupy consistence and scaling.

Description and Physical Properties—Soluble Ferric Pyrophosphate occurs in thin, apple-green, transparent scales, without odor, and having an acidulous slightly saline taste. The salt is permanent in dry air, when protected from light, but when unprotected soon becomes discolored.

It is freely and completely soluble in water; insoluble in alcohol. An aqueous solution of the salt is slightly acid to litmus.

Tests for Identity—Soluble Ferric Pyrophosphate, when boiled with sodium hydroxide T.S. produces a brownish-red precipitate without evolving ammonia.

Fuse 0.1 Gm. of the salt with 0.1 Gm. each of potassium nitrate and sodium carbonate, boil the residue with 10 cc. of distilled water and filter. The filtrate, after being rendered nearly, but not quite, neutral with highly dilute nitric acid, yields a yellow precipitate on the addition of silver nitrate T.S.

Tests for Purity—Boil an aqueous solution of the salt (1 in 10) with an excess of sodium hydroxide T.S. until the iron is precipitated, filter, strongly acidulate the filtrate with hydrochloric acid and cool. This liquid when mixed with an equal volume of magnesia mixture T.S., followed by a slight excess of ammonia water, yields a finely divided white precipitate, which, after collecting on a filter, and washing, does not turn yellow when treated with a few drops of silver nitrate T.S. (*phosphate*).

Assay—Dissolve about 1 Gm. of Soluble Ferric Pyrophosphate, accurately weighed, in 25 cc. of distilled water and 15 cc. of hydrochloric acid, in a glass-stoppered bottle, add 2 Gm. of potassium iodide, securely stopper the bottle, keep it at a temperature of 40° C. for thirty minutes, cool and then titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator.

Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

This assay is explained on page 1467.

Preserve it in well-closed containers, protected from light.

N. F. Preparation—Elixir Ferri Pyrophosphatis, Quininæ et Strychninæ.

Uses—This is one of the best of the ferruginous tonics. It is very largely used on account of its solubility, freedom from astringency and the ease with which it can be administered either in pills or in solution. The dose is two to five grains (0.13 to 0.3 Gm.).

FERRUM PEPTONATUM. N. F. Peptonized Iron [Ferr. Pepton.—Iron Peptonate]

Peptonized Iron is a compound of iron oxide and peptone, rendered soluble by the presence of sodium citrate. It contains not less than 16 per cent and not more than 18 per cent of Fe.

Description and Physical Properties—Dark brown, lustrous granules, or a brown powder. It has a slight characteristic odor.

Peptonized Iron is freely soluble in water yielding dark solutions. It is almost insoluble in alcohol.

Tests for Identity—The addition of acids to an aqueous solution of Peptonized Iron produces a precipitate which dissolves upon warming with an excess of hydrochloric acid. The resulting solution yields the reactions characteristic of ferric iron.

An aqueous solution of Peptonized Iron (1 in 20) is neutral or slightly alkaline to litmus paper.

An aqueous solution (1 in 50) yields no blue color upon the addition of potassium ferrocyanide T.S. (absence of *ionic iron*).

Tests for Purity—Dissolve 1 Gm. of Peptonized Iron in 50 cc. of distilled water, render the solution slightly alkaline, if necessary, by the addition of sodium hydroxide T.S., and precipitate the iron from the solution with hydrogen sulphide. Filter, add to the filtrate 5 cc. of diluted hydrochloric acid and evaporate almost to dryness on the water bath. Dissolve the residue in 10 cc. of distilled water, and to 5 cc. of the solution, rendered slightly alkaline with sodium hydroxide, add 2 cc. of alkaline cupric tartrate solution and heat. No red precipitate is produced (*sugar*).

Assay—Weigh accurately about 0.5 Gm. of Peptonized Iron and ignite it in a crucible to destroy the organic matter. Allow to cool, transfer the residue completely into a beaker, add 10 cc. of hydrochloric acid, heat until all the iron is dissolved, then add 10 cc. of hydrogen dioxide T.S., and evaporate almost to dryness on the water bath. Dissolve the residue by warming with 5 cc. of hydrochloric acid and 10 cc. of water, and transfer the solution completely into a glass-stoppered flask, filtering, if necessary, and washing the residue and filter with small quantities of hot water until free from iron. Now add to the solution 3 Gm. of potassium iodide, allow to stand for one-half hour at about 40° C., cool and titrate the liberated iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of iron (Fe).

This assay is explained on page 1467.

N. F. Preparations—Liquor Ferri Peptonati; Liquor Ferri Peptonati et Mangani.

Uses—This is used in the preparation of the corresponding N. F. solutions. It is supposed to be more readily assimilable than inorganic combinations of iron. The average dose is five grains (0.3 Gm.).

LIQUOR FERRI PEPTONATI. N. F. Solution of Peptonized Iron

[**Liq. Ferr. Pepton.**—Solution of Iron Peptonate]

	Metric	Alternative
Peptonized Iron	**17.50 Gm.**	256 gr.
Sodium Citrate	**20.00 Gm.**	292 gr.
Alcohol	**150.00 cc.**	4 fl. oz. 384 min.
Syrup	**50.00 cc.**	1 fl. oz. 288 min.
Glycerin	**50.00 cc.**	1 fl. oz. 288 min.
Oil of Orange	**0.15 cc.**	2⅓ min.
Acetic Ether	**0.20 cc.**	3 min.
Vanillin	**0.02 Gm.**	⅓ gr.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve the peptonized iron in 450 cc. [14 fl. oz. 192 min.] of warm distilled water, add the sodium citrate and warm the mixture until the salts have dissolved. Dissolve the oil of orange, vanillin and acetic ether in the alcohol and add to the first solution. Then add the syrup and glycerin, and, when cold, sufficient distilled water to make the product measure 1000 cc. [2 pints].

The N. F. IV solution was prepared by mixing 90 Gm. of fresh egg albumen with 450 cc. of distilled water and straining. Five cc. of hydrochloric acid and 1 Gm. of pepsin, dissolved in 25 cc. of distilled water, was then added and the mixture digested at from 40° to 50° C., until no cloudiness was produced by adding two drops of nitric acid to 4 cc. of the solution.

The liquid was then neutralized with NaOH solution and 120 cc. of freshly prepared solution of ferric oxychloride and 20 Gm. of sodium citrate added and warmed until a solution results. The other ingredients are then added, as above, to make 1000 cc.

Solution of Peptonized Iron is a golden-brown, transparent liquid, having an aromatic odor and a saline, somewhat astringent taste.

To 1 cc. of the Solution add 1 cc. of water and a few drops of diluted hydrochloric acid: the addition of 1 drop of potassium ferrocyanide T.S. causes an immediate dark blue precipitate.

A brown precipitate is formed upon acidulation with hydrochloric acid; this precipitate is redissolved upon the addition of ammonia water.

Preserve the Solution in dark amber-colored bottles.

Uses—This solution is used in anemias. It has the advantages over some other ferruginous preparations of being less disagreeable to the palate and not prone to disturb digestion. It is given in a dose of one to two fluidrachms (4 to 8 cc.).

A solution containing a protein product of iron, equivalent to 0.4 Gm. of metallic iron in 100 cc., known as *ovoferrin*, is manufactured by the A. C. Barnes Co.

LIQUOR FERRI PEPTONATI ET MANGANI. N. F. Solution of Peptonized Iron and Manganese

[Liq. Ferr. Pepton. et Mangan.—Solution of Iron Peptonate and Manganese]

	Metric	Alternative
Peptonized Iron	**17.50 Gm.**	256 gr.
Soluble Manganese Citrate	**8.75 Gm.**	128 gr.
Alcohol	**150.00 cc.**	4 fl. oz. 384 min.
Syrup	**50.00 cc.**	1 fl. oz. 288 min.
Glycerin	**50.00 cc.**	1 fl. oz. 288 min.
Oil of Orange	**0.15 cc.**	$2\frac{1}{3}$ min.
Acetic Ether	**0.20 cc.**	3 min.
Vanillin	**0.02 Gm.**	$\frac{3}{10}$ gr.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve the peptonized iron and soluble manganese citrate in 450 cc. (14 fl. oz. 192 min.) of warm distilled water. Dissolve the oil of orange, acetic ether and vanillin in the alcohol and add to the first solution. Then add the syrup and glycerin and when cold, sufficient distilled water to make the product measure 1000 cc. [2 pints].

Solution of Peptonized Iron and Manganese is a clear, reddish-brown liquid having a slight odor and taste.

Specific gravity: about 1.055 at 25° C.

Evaporate 10 cc. of the Solution on a water bath: it leaves not more than 1.812 Gm. of residue.

Incinerate the residue from 10 cc. of the Solution: it leaves not more than 0.255 Gm. of ash.

Dilute 5 cc. of the Solution with 5 cc. of distilled water, and add 4 drops of a saturated solution of potassium iodide and 4 cc. of mercuric nitrate T.S.: a yellow precipitate is formed (*peptonates*).

Dilute 5 cc. of the Solution with 5 cc. of distilled water and add 1 cc. of hydrochloric acid and a few drops of potassium thiocyanate T.S.: a blood red color is formed (*ferric iron*).

Treat the ash obtained in a preceding test with nitric acid with the aid of heat and take up with water and filter. To the filtrate add a few cc. of a 40 per cent ammonium persulphate solution and a few cc. of a 2 per cent silver nitrate solution: a pink color results (*manganese*).

Preserve the Solution in dark amber-colored bottles.

Uses—It combines the tonic properties of iron and manganese in a pleasantly flavored solution; the dose is two fluidrachms (8 cc.).

LIQUOR FERRI SALICYLATIS. N. F. Solution of Ferric Salicylate

[Liq. Ferr. Salicyl.—Salicylated Mixture of Iron]

	Metric	Alternative
Sodium Salicylate	**125.0 Gm.**	4 oz. av. 75 gr.
Tincture of Ferric Citrochloride	**125.0 cc.**	4 fl. oz.
Ammonium Carbonate	**6.5 Gm.**	95 gr.
Citric Acid	**8.5 Gm.**	124 gr.
Methyl Salicylate	**2.0 cc.**	31 min.
Glycerin	**175.0 cc.**	5 fl. oz. 288 min.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve the citric acid in 200 cc. [6 fl. oz. 192 min.] of distilled water, add the ammonium carbonate and dissolve the sodium Salicylate in this solution. Then add the tincture of ferric citrochloride, glycerin and the methyl salicylate, and, after mixing, sufficient distilled water to make the product measure 1000 cc. [2 pints].

Solution of Ferric Salicylate is a dark red liquid, with an odor of methyl salicylate, stronger when freshly prepared.

Acidulate 1 cc. of the Solution with hydrochloric acid: the red color changes to yellow and a voluminous crystalline precipitate of salicylic acid separates.

Add 5 cc. of ether to the acidulated liquid and shake, the liquid will separate into two clear layers. A portion of the upper layer, transferred to a watch glass and evaporated, yields a characteristic crystalline residue of salicylic acid, which gives a violet color with ferric chloride T.S. A portion of the lower layer gives a blue color with three drops of potassium ferrocyanide T.S. (*iron*).

Preserve the Solution in dark amber-colored bottles.

Uses—Ferric salicylate ordinarily insoluble, is soluble in the presence of ammonium citrate in this solution. It is employed in chronic rheumatism, associated with anemia. Dose, one to two fluidrachms (4 to 8 cc.).

LIQUOR FERRI SUBSULPHATIS. N. F. Solution of Ferric Subsulphate

(U. S. P. IX)

[**Liq. Ferr. Subsulph.**—Monsel's Solution, Solution of Basic Ferric Sulphate]

An aqueous solution containing basic ferric sulphate corresponding to not less than 20 Gm. and not more than 22 Gm. of Fe in each 100 cc.

	Metric	Alternative
Ferrous Sulphate	1045 Gm.	34 oz. av. 387 gr.
Sulphuric Acid	55 cc.	1 fl. oz. 365 min.
Nitric Acid		
Distilled Water, each, a sufficient quantity,		
To make	1000 cc.	2 pints

Add the sulphuric acid to 800 cc. [25 fl. oz. 288 min.] of distilled water in a capacious porcelain dish, heat the mixture nearly to 100° C., then add 75 cc. [2 fl. oz. 192 min.] of nitric acid and mix well. Divide the ferrous sulphate, coarsely powdered, into four approximately equal portions, and add these portions one at a time to the hot liquid, stirring after each addition until effervescence ceases. If, after the ferrous sulphate has dissolved, the solution is of a black color, add nitric acid, a few drops at a time, with heating and stirring, until red fumes cease to be evolved. Boil the solution until it assumes a red color and is free from nitric acid, as indicated by the test below, maintaining the volume at about 1000 cc. [2 pints] by the addition of distilled water as needed. Cool, add enough distilled water to make the product measure 1000 cc. [2 pints], and filter if necessary.

This solution sometimes crystallizes when cooled, forming a semi-solid whitish mass. When this occurs, the application of a gentle heat will restore the liquid condition.

Note—Solution of Ferric Subsulphate is to be dispensed when *Solution of Persulphate of Iron* has been prescribed by the physician.

When ferrous sulphate is added to a hot mixture of nitric and sulphuric acids, a copious evolution of reddish-brown vapors of N_2O_4 takes place, and the iron assumes a black tint, due to the formation of a compound of the ferrous sulphate with the nitric oxide with the oxygen of the air. This black color disappears under the influence of heat or the addition of more nitric acid, and, when effervescence ceases, a dark reddish-brown liquid is left, which is widely known as *Monsel's Solution.*

Ferric subsulphate differs from ferric tersulphate in that a smaller proportion of sulphuric acid than is required to satisfy the valence of the ferric iron is used. The following equation represents approximately what takes place in the reaction:

$$\underset{\text{ferrous sulphate}}{12FeSO_4} + \underset{\text{nitric acid}}{4HNO_3} + \underset{\text{sulphuric acid}}{3H_2SO_4} = \underset{\text{ferric subsulphate}}{3Fe_4O(SO_4)_5} + \underset{\text{nitric oxide}}{4NO} + \underset{\text{water}}{5H_2O}$$

Solution of Ferric Subsulphate is a dark, reddish-brown liquid, odorless or nearly so, of an acid, strongly styptic taste, an acid reaction, and miscible with water and alcohol without decomposition.

Specific gravity: about 1.548 at 25° C.

Separate portions of an aqueous dilution of the Solution (1 in 20) yield a brownish-red precipitate with ammonia water, a blue precipitate with potassium ferrocyanide T.S., and a white precipitate, insoluble in hydrochloric acid, with barium chloride T.S.

Add a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of sulphuric acid and an aqueous dilution of the Solution (1 in 10): the crystal does not become brown, nor does a brownish-black color develop around it (*nitric acid*).

Add a few drops of freshly prepared potassium ferrocyanide T.S. to 2 cc. of an aqueous dilution of the Solution (1 in 20): a brown color is produced without a tinge of green or greenish-blue (*ferrous salt*).

Assay—Dilute 1 cc. of the Solution, accurately measured, with 25 cc. of distilled water, add 5 cc. of hydrochloric acid and 2 Gm. of potassium iodide, stopper the flask containing the mixture and allow to stand for 30 minutes at a temperature of 40° C. Cool the liquid, dilute it with 50 cc. of water and titrate it with tenth-normal sodium thiosulphate, starch T.S. being used as indicator.

Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe. Each cubic centimeter of Solution of Ferric Subsulphate corresponds to not less than 35.8 cc. and not more than 39.3 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1467.

Preserve the Solution in well-stoppered, amber-colored bottles in a moderately warm place (not under 22° C.).

Uses—This preparation is probably the most valuable official styptic solution. It is less irritating than the solution of ferric sulphate, owing to the smaller proportion of sulphuric acid. It is used externally in stopping hemorrhages, and internally in doses of three to six minims (0.2 to 0.4 cc.), largely diluted with water.

Unofficial Salts of Iron

Ferri Acetas, $Fe(C_2H_3O_2)_3$ Ferric Acetate	Brownish-red, crystalline scales; soluble in water. Used in textile dyeing and as a tonic, in doses of from 3 to 10 grains (0.2 to 0.6 Gm.)
Ferri Arsenas, $Fe_3(AsO_4)_2.6H_2O$ Ferrous Arsenate	A green, amorphous powder; insoluble in water. It is used in medicine as an alterative. Dose, $\frac{1}{20}$ to $\frac{1}{8}$ grain (0.004 to 0.008 Gm.)
Ferri Benzoas, $Fe(C_7H_5O_2)_3.3H_2O$ Ferric Benzoate	A brown powder; insoluble in water, soluble in cod liver oil. Dose, 1½ to 3 grains (0.1 to 0.2 Gm.)
Ferri Bromidum, $FeBr_2$ Ferrous Bromide	A yellowish, crystalline powder; soluble in water. It is deliquescent and is used as an alterative and tonic. Dose, 1 to 3 grains (0.06 to 0.2 Gm.)
Ferri et Quininæ Citras (U. S. P. IX) Iron and Quinine Citrate	Iron and quinine citrate rendered more soluble by the presence of ammonium citrate. It should contain not less than 11.5 per cent of anhydrous quinine and not less than 13 per cent of iron. In thin, transparent scales, of a greenish or golden-yellow color; deliquescent and very soluble in water. The dose is 4 grains (0.25 Gm.)
Ferri et Sodii Pyrophosphas Iron and Sodium Pyrophosphate	Grayish-white scales or granular powder; slowly soluble in water. It is used as a tonic and astringent. Dose, 3 to 15 grains (0.2 to 1 Gm).
Ferri et Strychninæ Citras Iron and Strychnine Citrate	Garnet to brown, transparent, bitter scales; soluble in water. It is used as a tonic. Dose, 2 to 5 grains (0.12 to 0.3 Gm.)
Ferri et Ammonii Sulphas Ferric Ammonium Sulphate	Commonly called *ferric-alum*. Lilac to violet, efflorescent crystals having an acid and styptic taste. It is readily soluble in water and is used chiefly as an indicator in analytical chemistry
Ferri et Ammonii Tartras Iron and Ammonium Tartrate	Reddish-brown to garnet-brown, thin, transparent scales; soluble in water. It is used as a mild chalybeate. Dose, 5 to 20 grains (0.3 to 1.2 Gm.)
Ferri et Potassii Tartras Ferric and Potassium Tartrate	Garnet-red to reddish-brown scales; having a sweet ferruginous taste; soluble in water. This compound is used as a tonic and chalybeate. Dose, from 5 to 10 grains (0.3 to 0.6 Gm.)
Ferri Ferrocyanidum, $Fe_4(FeCN_6)_3$ Ferric Ferrocyanide	Commonly called *Prussian blue*. A dark blue powder; insoluble in water. It is the product formed when ferric salts are identified by means of potassium ferrocyanide yellow solution. It is used as a pigment in paints, in ink, and in bluing It has some use in medicine as a tonic. Dose, 2 to 5 grains (0.12 to 0.3 Gm.)
Ferri Hydroxidum Ferric Hydroxide Magma Ferri Hydroxidi (N. F. IV)	Prepared by adding 100 cc. of solution of ferric sulphate, previously diluted with 1000 cc. of cold water, to 138 cc. of ammonia water, which has been diluted with 500 cc. of cold water. Wash the magma thoroughly, drain on a strainer and add water to make 300 Gm. It is used as a basis for preparing iron salts such as the citrate, tartrate, and as an antidote to arsenic.
Ferri Nitras, $Fe(NO_3)_3$ Ferric Nitrate	Gray-white crystals; soluble in water. It is used as a mordant in dyeing and in calico-printing. It is also used as a tonic and astringent
Ferri Lactas, $Fe(C_3H_5O_3)_2.3H_2O$ Ferrous Lactate	Greenish-white crystals or small green scales; soluble in water. It is used as a tonic and alterative. Dose, 1 to 5 grains (0.06 to 0.3 Gm.)
Ferri Oxalas, $FeC_2O_4.2H_2O$ Ferrous Oxalate	A pale-yellow, odorless, crystalline powder; practically insoluble in water. It is used as a developer in photography, also as a tonic and alterative. Dose, 2 to 5 grains (0.12 to 0.3 Gm.)
Ferri Oxidum Magneticum, Fe_3O_4 Magnetic Iron Oxide	Also called *ferroso-ferric oxide*. A reddish-black, amorphous powder insoluble in water. It is used as an hematic tonic. Dose, 2 to 10 grains (0.12 to 0.6 Gm.)
Ferri Oxidum Rubrum, Fe_2O_3 Red Oxide of Iron	A dense, red powder; insoluble in water. It is chiefly used as a pigment in the manufacture of pottery and glass, and as a polishing powder
Ferri Phosphas Albus, $FePO_4.4H_2O$ White Ferric Phosphate	A yellowish-white powder; insoluble in water. It is used as a 10 to 20 per cent solution in diluted phosphoric acid, for carious teeth to which it is applied on cotton
Ferri Salicylas, $Fe(C_7H_5O_3)_3$ Ferric Salicylate	A violet-gray powder; slightly soluble in water. It is used in medicine as an astringent, antiseptic, and antirheumatic. Dose, 3 to 10 grains (0.2 to 0.6 Gm.)
Ferri Subcarbonas Ferric Oxyhydrate	A reddish-brown powder; insoluble in water. It is used as a mild chalybeate. Dose, 3 to 15 grains (0.2 to 1 Gm.)
Ferri Sulphidum, FeS Ferrous Sulphide	Dark brown or black metallic pieces, sticks, or granules. It is insoluble in water but is dissolved by acids with the evolution of hydrogen sulphide. It is used chiefly in the preparation of hydrogen sulphide
Ferri Valeras Ferric Valerate	An amorphous, brownish-red powder, with a valerian-like odor. It is insoluble in water and is used as a tonic and nervine. Dose, 3 to 15 grains (0.2 to 1 Gm.)

Chromium, Cr; 52.0

The word *chromium* is from the Greek and means color, alluding to the various colors exhibited by its compounds. It is found in nature as chrome-iron ore, deposits of which are found in southeastern Pennsylvania, but more largely in New Caledonia, Rhodesia, and Russia. It has been prepared by reducing Cr_2O_3 with carbon in the electric furnace, also by the alumino-thermic process whereby chromium oxide is reduced by finely powdered aluminum, when they are mixed and ignited. This metal is brittle, of a grayish-white color, and very hard, being capable of scratching glass. Its specific gravity is about 6.9. It forms a number of compounds with oxygen. Of these the monoxide, CrO, and the sesquioxide, Cr_2O_3, are well-known and are basic in char-

acter. The latter is useful as a green pigment. The chromium trioxide or chromic anhydride, CrO_3, is red and is the oxide of pharmaceutical interest. It is strongly acidic since it represents the anhydride of an acid of the formula H_2CrO_4.

Tests for Chromium Salts

Solutions of chromates or dichromates, free from mineral acids, yield with lead acetate T.S. a yellow precipitate, which is insoluble in acetic acid. When a chromate or a dichromate is acidulated with diluted sulphuric acid and hydrogen dioxide T.S. added, a blue color is produced. Upon shaking with ether, the blue color passes into the ethereal layer.

CHROMII TRIOXIDUM. U.S. Chromium Trioxide

[Chrom. Triox.—"Chromic Acid," Chromic Anhydride]

Chromium Trioxide contains not less than 95 per cent of CrO_3 (100.00).

Caution—Chromium Trioxide should not be brought into intimate contact with organic substances, as serious explosions are liable to result.

Preparation—Chromium trioxide, or chromic acid, as it is usually called, is readily obtained by mixing one hundred volumes of a cold saturated solution of potassium dichromate with one hundred and fifty volumes of sulphuric acid, and allowing the mixture to cool. The sulphuric acid unites with the potassium, and sets free the chromium trioxide, which is deposited in crystals. The mother liquor having been poured off, the crystals are transferred to a glass funnel, and the mother liquor displaced by nitric acid; they are then placed upon a porous tile to drain, and finally dried at from 60° to 80° C. to remove nitric acid.

$$\underset{\text{potassium dichromate}}{K_2Cr_2O_7} + \underset{\text{sulphuric acid}}{2H_2SO_4} = \underset{\text{chromium trioxide}}{2CrO_3} + \underset{\text{acid potassium sulphate}}{2KHSO_4} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—Small, needle-shaped crystals or rhombic prisms, of a dark purplish-red color and metallic luster. It is odorless, and is deliquescent in moist air. Chromium Trioxide is destructive to animal and vegetable tissues.

One Gm. of Chromium Trioxide is soluble in 0.6 cc. of water at 25° C. One Gm. is soluble in 0.5 cc. of boiling water. When Chromium Trioxide is brought into contact with organic solvents (*e.g.*, alcohol), decomposition takes place, sometimes with dangerous violence.

When Chromium Trioxide is heated, it darkens and finally becomes black, but the color is restored on cooling. At about 190° C. it fuses to a reddish-brown liquid, which on cooling forms a dark red, brittle mass (often enclosing cavities filled with crystals), yielding a scarlet powder. Above 250° C. it begins to decompose into green chromic oxide and free oxygen, and after protracted heating leaves a residue of green chromic oxide.

Tests for Identity—When Chromium Trioxide is warmed with hydrochloric acid, chlorine is evolved.

Chromium Trioxide responds to the reactions for chromates, page 733.

Tests for Purity—A solution of 1 Gm. of Chromium Trioxide in 100 cc. of distilled water, previously acidulated with 3 cc. of hydrochloric acid, is not rendered turbid within one minute on the addition of 1 cc. of barium chloride T.S. (*sulphuric acid*).

Assay—Dissolve about 1 Gm. of Chromium Trioxide, accurately weighed in a stoppered weighing bottle, in sufficient distilled water to make 100 cc. Mix 15 cc. of this solution with 3 cc. of hydrochloric acid and 2 Gm. of potassium iodide in a glass-stoppered container, agitate the mixture, allow it to stand for five minutes, then dilute it with 100 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.003333 Gm. of CrO_3.

This assay is explained on page 1466.

Preserve in glass-stoppered bottles.

Uses—Chromium trioxide is a powerful caustic and antiseptic. It is a very effective caustic in destroying warty growths. It is not used internally.

Unofficial Salts of Chromium

Chromii Bromidum, Cr_2Br_6 Chromium Bromide	An olive-green crystalline powder; insoluble in water. It is of little importance
Chromii Chloridum, $CrCl_3$ Chromium Chloride	A reddish-violet, crystalline powder. The anhydrous salt is insoluble in water but soluble in the presence of a trace of stannous chloride. The hydrous salt is water soluble. It is used as a mordant and in the manufacture of other chromium salts
Chromii Dichloridum, $CrCl_2$ Chromium Dichloride	The anhydrous salt is white but dissolves in water to form a blue solution which takes up oxygen and becomes green. The salt is a powerful reducing agent
Chromii Fluoridum, $CrF_3.4H_2O$ Chromium Fluoride	A green, crystalline powder, soluble in water. It corrodes glass and therefore should be kept in lead or wooden vessels. It is used in the printing and dyeing of woolen goods
Chromii Oxidum, Cr_2O_3 Chromic Oxide	Also known as *chromium sesquioxide* and as *chrome green*. A bright green, crystalline powder; insoluble in water and in acids. This compound is used as a green pigment because of its fine color and great permanence
Chromii Sulphas, $Cr_2(SO_4)_3.15H_2O$ Chromic Sulphate	Violet crystals, soluble in water, yielding a bluish-violet solution which becomes green on boiling. The double sulphate of chromium with potassium, sodium, or ammonium constitutes what is called a *chrome alum*

Uranium, U; 238.2

Uranium was named by its discoverer in honor of the planet Uranus. It is found in nature chiefly in the mineral *uraninite* (*uranite*) or *pitchblende*, which consists largely of U_3O_8, and in the mineral *carnotite*. It may be prepared by reducing the oxide with carbon in the electric furnace, or by reducing uranous chloride, UCl_4, with sodium. It is a white, malleable metal, fairly hard but softer than steel. Its specific gravity is very high; 18.7. In contact with air it tarnishes slowly. It is closely related chemically to chromium, molybdenum, and tungsten, and two classes of compounds, *i. e.*, *uranous*, derived from the oxide UO_2, and *uranyl*, containing the divalent group UO_2. It is especially well known because of its connection with radium. Becquerel, in 1896, discovered that pitchblende emitted special radiations, capable of influencing a photographic plate, and he attributed these properties to uranium, but in 1898 and 1899 Madame Curie and her husband Professor Curie showed that these properties were not due to the presence of uranium but to another substance to which they gave the name *radium*.

Uranium compounds are used in glass manufacture to produce a greenish-yellow glass, known as *uranium glass*.

Unofficial Salts of Uranium

Uranus Sulphate, $U(SO_4)_2.4H_2O$	Green crystals; decomposed by water. It is dissolved by dilute acids and is used as a reagent
Uranyl Acetate, $UO_2(C_2H_3O_2)_2.2H_2O$	Small yellow crystals; decomposed by light, soluble in cold water but decomposed by hot water. This salt is used in medicine and as a chemical reagent
Uranii Nitras, $UO_2(NO_3)_2.6H_2O$ (U. S. P. IX) Uranium Nitrate	Light yellow prisms; radioactive and somewhat efflorescent. It is very soluble in water. This salt should be used with caution. It has been used in the treatment of diabetes. The dose is ⅙ grain (0.01 Gm.)
Uranyl Sulphate, $(UO_2)SO_4.3H_2O$	A yellow, crystalline salt; soluble in water. When fused with glass, it imparts a greenish-yellow fluorescence. This salt is chiefly used as a laboratory reagent

CHAPTER LIII

NICKEL, COBALT, AND TIN

Ni; 58.68. Co; 58.97. Sn; 118.7

THE name *nickel* is from the German term "kupfer nickel", meaning false copper, because of the resemblance of a nickel ore (*niccolite*) to an ore of copper.

These metals and their compounds are not considered of sufficient medicinal importance to give them a place in the U. S. Pharmacopœia. Their salts are sometimes used medicinally, and several are among the official reagents. Two of the metals, nickel and tin, are important in many respects, particularly in the arts.

Nickel, Ni; 58.68

This metal is found in the magnetic iron pyrites of Sudbury, Ontario. Also as arsenic or *kupfer nickel* in Germany and Sweden, and as a mixed silicate called *garnierite* (or *genthite*), $2(Ni.Mg)\ Si_4O_{13} + 2H_2O$, in New Caledonia, Nova Scotia, and Norway. Its specific gravity ranges from 8.35 to 8.9 according to mechanical treatment. It is a white, malleable metal, and forms with copper and zinc a valuable alloy, known as *German silver*. This alloy is also used for making coins, for plating other metals, for manufacturing scale pans and laboratory utensils, and for many other purposes. Some of the salts have come into use as medicines; the Latin name of the metal is *niccolum*.

Tests for Compounds of Nickel

1. Ammonium sulphide produces with a solution of a nickel salt a black precipitate (sulphide). This precipitate is insoluble in diluted hydrochloric acid, but soluble in hot nitric acid.

2. Potassium or sodium hydroxide produces with nickel salts pale green precipitates of hydroxide insoluble in an excess.

3. Potassium cyanide produces a green precipitate with a solution of a nickel salt, soluble in an excess, but reprecipitated by hydrochloric acid.

Unofficial Salts of Nickel

Niccoli Bromidum, $NiBr_2$ Nickel Bromide	Brownish to golden-yellow, lustrous scales. Very hygroscopic and very soluble in water. It is used in medicine
Niccoli Carbonas, $NiCO_3$ Nickel Carbonate	A pale green to bluish-green, crystalline powder; insoluble in water. It is occasionally used in medicine
Niccoli Chloridum, $NiCl_2$ Nickel Chloride	Golden-yellow scales, deliquescent in moist air; very soluble in water. The hydrated salt is green. The anhydrous salt absorbs ammonia to form a white addition compound. Nickel chloride is used in sympathetic ink, as an antiseptic, and in gas masks to absorb ammonia
Niccoli Cyanidum, $Ni(CN)_2$ Nickel Cyanide	Poisonous, apple-green powder. Insoluble in water but soluble in an excess of potassium cyanide solution. Nickel cyanide is used in metallurgy and in electro-plating
Nickelous Oxide, NiO	A green, crystalline powder turning yellow when heated. It is insoluble in water and is used in the manufacture of nickel salts and in painting porcelain
Nickelic Oxide, Ni_2O_3	An insoluble grayish-black powder. It is decomposed by heat and is used in storage batteries and for producing oxygen on a small scale
Niccoli Sulphas, $NiSO_4 + 7H_2O$ Nickel Sulphate	The anhydrous salt is yellow but the hydrated salt is blue or green, depending upon the amount of water present. The salt is water-soluble and is used in nickel plating in the form of the double nickel and ammonium sulphate. Nickel sulphate is also used as a mordant in printing textiles
Nickel Sulphide, NiS	It is prepared by the action of alkali sulphides on solutions of soluble salts of nickel. When made by precipitation it is a black, insoluble, crystalline powder

Cobalt, Co; 58.97

The name *cobalt* is from Kobold, the demon of the German mines. The metal is usually found associated with arsenical ores in *cobaltite*, $CoAs_2.CoS_2$, and *smaltite*, $CoAs_2$. It is white, tough, and brittle, unalterable in the air, and strongly magnetic. Specific gravity about 8.8. It forms two classes of salts, cobaltous and cobaltic, in this respect resembling iron. The native ore *skutterudite*, $CoAs_3$, and other cobalt minerals containing arsenic, are often sold in commerce under the name of *flystone*. This material is used as a fly-poison by breaking it into small fragments and mixing them with sweetened water. The *chloride* and *sulphocyanate* have been used to make *barometer paper*, by dipping ordinary white paper into a solution and drying it; when dry the color is blue, but an increase of moisture in the air changes the color to pink. Salts of cobalt are used to give glass a blue color.

Cobaltous chloride is used officially as a reagent (see Chapter XCII). No other salts are official, and none of the unofficial salts is of pharmaceutical interest.

Tests for Salts of Cobalt

Solutions of cobaltous compounds yield a blue precipitate with sodium hydroxide T.S. This precipitate rapidly changes color, becoming olive-green, and, if boiled soon after its formation, becomes rose-red. Solutions of cobalt salts, when treated with an excess of potassium nitrite and acetic acid, yield a yellow precipitate.

Tin, Sn; 119.0

The exact origin of the word *tin* is unknown. The Latin name "stannum" was originally applied to an alloy but later to tin proper. The oxide (*cassiterite* or *tinstone*, SnO_2) is the form in which tin is usually found. Tin is a valuable white metal, of a silvery color, which, when bent, emits a peculiar crackling sound, termed the "cry of tin". Its specific gravity is 7.3. It forms two classes of compounds, called *stannous* and *stannic* salts. These are not used to any extent in medicine or pharmacy, but are of great importance in the arts. Stannous chloride is used officially in the arsenic test.

Tests for Compounds of Tin

When metallic zinc is placed in a solution of a salt of tin acidified with hydrochloric acid, the tin is precipitated in metallic form. The precipitated metal is soluble in boiling hydrochloric acid and the resulting solution yields a white or gray precipitate with mercuric chloride T.S.

Unofficial Salts of Tin

Stanni Chloridum, $SnCl_2.2H_2O$ Stannous Chloride (tin salt)	White, crystalline masses or prismatic needles. Soluble in water but easily converted into the insoluble oxychloride by absorbing oxygen from the air. It is largely used as a reducing agent and as a mordant (see Reagents, page 1542)
Stanni Hydroxidum, $Sn(OH)_2$ Stannous Hydroxide	A yellowish-white powder, insoluble in water but soluble in an excess of caustic potash or caustic soda to form stannites. It yields stannous salts upon treatment with acids
Stanni Sulphidum, SnS Stannous Sulphide	When made by precipitation from stannous chloride solution with hydrogen sulphide, it is a dark brown powder. When made by heating tin with sulphur, it forms a gray, crystalline mass. This compound is of interest as it is the compound found in the qualitative identification of stannous salts with hydrogen sulphide
Sodii Stannas, Na_2SnO_3 Sodium Stannate	Commonly called "preparing salt". It is found in white, crystalline powder or lumps, soluble in water, and is used as a mordant in dyeing
Acidum Stannicum, H_2SnO_3 Stannic Acid	The true metastannic acid. A white, crystalline powder, insoluble in water. When fused with caustic alkali, it is converted into soluble stannate. It is used in *putty powder*, a polishing agent, in the preparation of salts of tin and in the textile industry

CHAPTER LIV

LEAD, COPPER, SILVER, AND MERCURY

Pb; 207.20. Cu; 63.57. Ag; 107.88. Hg; 200.6

THIS group embraces four well-known metals, which furnish compounds of great value as medicines. They are allied to one another chemically, although they differ greatly in their physical properties.

Lead, Pb; 207.20

The name *lead* is translated from several words meaning a weight or a plummet. The Latin name *plumbum* is the root of the common word plumber, as he was originally a worker in lead. It is obtained from the native sulphide, *galena*, or *galenite*, by roasting in a reverberatory furnace until a part of the sulphide is changed into lead oxide and lead sulphate. The air supply is then cut off and the temperature increased when a reaction takes place as follows:

$$\underset{\text{lead sulphide}}{2PbS} + \underset{\text{lead sulphate}}{PbSO_4} + \underset{\text{lead oxide}}{2PbO} = \underset{\text{lead}}{5Pb} + \underset{\text{sulphur dioxide}}{3SO_2}$$

It is often associated with silver. It is a heavy, soft, ductile, bluish metal, with a specific gravity of 11.37. It melts at 327° C. Lead forms three well-known compounds with oxygen: 1. The monoxide or litharge, PbO. 2. The dioxide or peroxide, PbO_2. 3. The triplumbic tetroxide, Pb_3O_4, commonly called *red lead* or *minium*.

Tests for Compounds of Lead

Solutions of lead salts yield with diluted sulphuric acid a white precipitate which is slightly soluble in diluted hydrochloric or nitric acid, but completely soluble in warm sodium hydroxide T.S. With potassium chromate T.S., solutions of lead salts, free or nearly free from mineral acids, yield a yellow precipitate which is insoluble in acetic acid but soluble in sodium hydroxide T.S.

Poisonous Properties of Lead and Its Compounds

Pure water dissolves appreciable quantities of lead through the formation of a slightly soluble hydroxide or carbonate. If sulphates or carbonates are present in the water, an insoluble coating is formed on the surface of the metal, which protects it from further action. Lead pipes and lead tanks should only be used for "hard water".

PLUMBI ACETAS. U. S. Lead Acetate

[**Plumb. Acet.**—SUGAR OF LEAD]

Lead Acetate contains not less than 85.31 per cent and not more than 89.57 per cent of $Pb(C_2H_3O_2)_2$, corresponding to not less than 99.5 per cent of the crystallized salt [$Pb(C_2H_3O_2)_2.3H_2O = 379.32$].

Preparation—This important salt is made by adding lead oxide to acetic acid and gently heating the mixture until combination takes place.

$$\underset{\text{lead oxide}}{PbO} + \underset{\text{acetic acid}}{2HC_2H_3O_2} = \underset{\text{lead acetate}}{Pb(C_2H_3O_2)_2} + \underset{\text{water}}{H_2O}$$

The commercial or technical salt is unfit for pharmaceutical uses; it is not expected to be pure, and usually contains both carbonate and oxide. The official salt is thus described:

Description and Physical Properties—Colorless, shining, transparent, monoclinic prisms or plates, or heavy, white, crystalline masses or granular crystals. It has a faintly acetous odor, is efflorescent, and absorbs carbon dioxide on exposure to air.

One Gm. of Lead Acetate is soluble in 1.4 cc. of water, and in 38 cc. of alcohol, at 25° C. One Gm. is soluble in about 0.5 cc. of boiling water. It is freely soluble in glycerin.

When heated to 40° C., the salt loses its water of crystallization. When heated rapidly to 75° C., it liquefies in its water of crystallization, and at a temperature above 280° C. is decomposed, leaving a residue of finely divided metallic lead and lead oxide.

Tests for Identity—An aqueous solution of Lead Acetate (1 in 10) is slightly alkaline to litmus paper, and responds to the reactions for lead, page 737, and for acetates, page 800.

Tests for Purity—A solution of the salt (1 in 10) prepared with recently boiled, distilled water, is clear, or only slightly opalescent (*carbonate*), and yields with potassium ferrocyanide T.S. a precipitate which is neither blue nor red (*iron or copper*).

Assay—Dissolve about 5 Gm. of Lead Acetate, accurately weighed, in sufficient recently boiled, distilled water to make exactly 100 cc. Mix 10 cc. of this solution with 50 cc. of tenth-normal oxalic acid in a 200 cc. measuring flask, agitate the mixture thoroughly for five minutes and fill the flask to the mark with distilled water. Filter, and titrate the residual oxalic acid in 100 cc. of the filtrate with tenth-normal potassium permanganate, the filtrate being previously acidulated with 10 cc. of sulphuric acid and warmed to 80° C. Each cc. of tenth-normal oxalic acid corresponds to 0.01626 Gm. of $Pb(C_2H_3O_2)_2$.

This assay is explained on page 1473.

Preserve in well-closed containers.

U. S. P. Preparation—Liquor Plumbi Subacetatis.

N. F. Preparations—Liquor Alumini Acetatis; Lotio Alba Veterinaria; Lotio Plumbi et Opii; Mistura Adstringens; Pilulæ Opii et Plumbi.

Uses—Lead acetate is a valuable astringent and sedative; it is used both internally and externally. The dose is from one to three grains (0.065 to 0.2 Gm.). Its solution in water is usually turbid, due to the formation of a trace of carbonate through the carbonic acid present in the water; diluted acetic acid dissolves this precipitate and makes a clear solution.

Antidotes—(See Part XV, on Antidotes).

LIQUOR PLUMBI SUBACETATIS. U. S. Solution of Lead Subacetate

[Liq. Plumb. Subacet.—GOULARD'S EXTRACT]

An aqueous solution containing lead subacetate, approximately $Pb_2O(CH_3.COO)_2$, corresponding to not less than 18 per cent of Pb.

	Metric	Alternative
Lead Acetate	**220 Gm.**	3 oz. av. 294 gr.
Lead Monoxide	**140 Gm.**	2 oz. av. 147 gr.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	1 pint

Triturate the lead monoxide to a smooth paste with 100 cc. [1½ fl. oz.] of distilled water, and transfer the mixture to a bottle of about 1000 cc. [1 pint] capacity, using an additional 100 cc. [1½ fl. oz.] of distilled water for rinsing. Dissolve the lead acetate in 700 cc. [11 fl. oz.] of distilled water, and add the solution to the lead oxide mixture. Shake vigorously for five minutes, then set it aside for seven days, shaking frequently during this time. Finally filter, protecting the solution from undue contact with the air, and pass enough distilled water through the filter to make the product measure 1000 cc. [1 pint].

This solution may also be prepared as follows:

Boil the mixture of lead acetate, lead monoxide, and water for half an hour in a suitable flask, adding small portions of distilled water as necessary to maintain the volume, then cool, and filter. The funnel during filtration should be covered to protect the solution from the action of air, and enough

boiled distilled water passed through the filter to make the product measure 1000 cc. [1 pint].

The object of this process is to furnish a concentrated solution of a lead compound containing a small proportion of acetic acid. The "subacetate" is not a definite salt, but as found in the official solution is a mixture of oxyacetates, produced by boiling the normal acetate in water, in contact with the oxide, or by permitting the mixture to stand with occasional shaking, during seven days.

$$\underset{\text{lead oxide}}{3PbO} + \underset{\text{lead acetate}}{3Pb(C_2H_3O_2)_2} = \underset{\text{lead oxyacetates}}{Pb_3O(C_2H_3O_2)_4} + Pb_3O_2(C_2H_3O_2)_2$$

Description and Physical Properties—A clear, colorless, odorless liquid, having a very sweet, astringent taste. It is alkaline to litmus paper but not to phenolphthalein T.S. On exposure to the air it absorbs carbon dioxide, which causes the formation of a white precipitate.

Tests for Identity—Specific gravity: about 1.25 at 25° C.

When 1 cc. of Solution of Lead Subacetate is added to 5 cc. of mucilage of acacia (1 in 10), it produces a dense white precipitate (*distinction from normal lead acetate*).

Solution of Lead Subacetate responds to the reactions for lead, page 737, and for acetates, page 800.

Test for Purity—Solution of Lead Subacetate yields with potassium ferrocyanide T.S. a white precipitate, tinged with neither red nor blue (*copper or iron*).

Assay—Place about 1 cc. of Solution of Lead Subacetate, accurately weighed, in a 200 cc. volumetric flask, dilute with 50 cc. of recently boiled distilled water, and add 50 cc. of tenth-normal oxalic acid. Agitate the mixture thoroughly for five minutes, fill to the mark with distilled water, shake, and filter, rejecting the first 20 cc. of the filtrate. Add 5 cc. of sulphuric acid to 100 cc. of the filtrate, warm to about 70° C., and titrate the residual oxalic acid with tenth-normal potassium permanganate. Each cc. of tenth-normal oxalic acid corresponds to 0.01036 Gm. of Pb.

This assay is explained on page 1473.

Preserve in well-stoppered bottles.

N. F. Preparations—Ceratum Plumbi Subacetatis; Liquor Plumbi Subacetatis Dilutus.

History—This preparation was first prepared and used by Thomas Goulard, a surgeon of Montpellier, France, in the 18th century. He published an account of it in a book called "The Extract of Saturn". The preparation of lead acetate itself, called *Saccharum Saturni* in the older literature was attributed to Basil Valentine.

Uses—This solution is sedative and astringent; it is employed externally as an application to bruises and sprains.

Antidotes—(See Part XV, on Antidotes).

PLUMBI MONOXIDUM. U. S. Lead Monoxide

[**Plumb. Monoxid.**—Plumbi Oxidum U. S. P. IX, Litharge]

Lead Monoxide, when freshly ignited, contains not less than 97 per cent of PbO (223.20).

Preparation—Litharge is lead oxide which has been rendered semi-crystalline by incomplete fusion. Almost all the litharge of commerce is obtained as a secondary product in the process for extracting silver from argentiferous galenite. After extracting the lead from the ore, the alloy is calcined in the open air, whereby the lead becomes oxidized, and by fusion passes into the state of litharge, while the silver remains unchanged. It is also made by directly heating lead in a current of air. Litharge is officially described as follows:

Description and Physical Properties—A heavy, yellowish or reddish-yellow powder, or minute scales, without odor or taste. On exposure to the air it slowly absorbs moisture and carbon dioxide.

Lead Monoxide is almost insoluble in water, to which, however, it imparts a faintly alkaline reaction. It is insoluble in alcohol. The Monoxide is dissolved by acetic acid, by diluted nitric acid, and by warm solutions of the hydroxides of fixed alkalies.

Test for Identity—When heated, the Monoxide becomes darker in color, but assumes its original color on cooling. It fuses at a red heat. When heated in contact with charcoal, it is reduced to metallic lead.

A solution of the Monoxide in diluted nitric acid (1 in 10) is colorless, and when nearly neutralized by ammonia T.S. responds to the reactions for lead, page 737.

Tests for Purity—Shake 5 Gm. of the Monoxide in a small flask with 5 cc. of distilled water and add 20 cc. of acetic acid. Boil the mixture for a few minutes, filter, wash the insoluble residue thoroughly with diluted acetic acid, and dry at 110° C.: the residue weighs not more than 0.10 Gm.

When strongly heated in a porcelain crucible, the Monoxide loses not more than 4 per cent of its weight (*carbonate or moisture*).

Assay—Dissolve about 0.4 Gm. of freshly ignited Lead Monoxide, accurately weighed, in 2 cc. of glacial acetic acid and 25 cc. of recently boiled, distilled water, in a 200 cc. volumetric flask, and mix the solution with 50 cc. of tenth-normal oxalic acid. Fill the flask to the 200 cc. mark with distilled water, mix well, filter through a dry filter into a dry flask, rejecting the first 20 cc. of filtrate, and titrate the residual oxalic acid in 100 cc. of the filtrate with tenth-normal potassium permanganate, the filtrate being previously acidulated with 20 cc. of diluted sulphuric acid, and warmed to 80° C. Each cc. of tenth-normal oxalic acid corresponds to 0.01116 Gm. of PbO.

This assay is explained on page 1473.

Preserve in well-closed containers.

U. S. P. Preparations—Emplastrum Plumbi Oleatis; Liquor Plumbi Subacetatis.

Uses—Lead Oxide is used officially for making several preparations (see above).

PLUMBI IODIDUM. N. F. Lead Iodide

[Plumb. Iod.]

Lead Iodide contains, when dried over sulphuric acid for 24 hours, not less than 99 per cent of PbI_2 (461.04).

Preparation—This iodide may be made by dissolving equal weights of lead nitrate and potassium iodide in sufficient distilled water to form solutions of each, then mixing the solutions. The precipitate of lead iodide is then collected on a filter, washed with distilled water and dried at a gentle heat.

This is an instance of double decomposition, lead iodide and potassium nitrate being formed. The nitrate is preferred to the acetate, because lead iodide is more soluble in solution of potassium acetate than in that of potassium nitrate. The following equation represents the reaction that takes place:

$$\underset{\text{potassium iodide}}{2KI} + \underset{\text{lead nitrate}}{Pb(NO_3)_2} = \underset{\text{lead iodide}}{PbI_2} + \underset{\text{potassium nitrate}}{2KNO_3}$$

Description and Physical Properties—Lead Iodide occurs as a heavy, bright yellow powder, without odor or taste; permanent in the air.

One Gm. dissolves in about 1300 cc. of water at 25° C. and in about 200 cc. of boiling water, separating from the latter solution on cooling in brilliant, golden yellow, crystalline laminæ; very slightly soluble in alcohol; soluble without color, in solutions of the fixed alkalies, in concentrated solutions of the alkali acetates, of potassium iodide, and of sodium thiosulphate, and in a hot solution of ammonium chloride.

Tests for Identity—When moderately heated, the salt fuses to a thick, reddish-brown liquid, which congeals, on cooling, to a yellow, crystalline mass. At a higher temperature it is decomposed with the evolution of violet vapors of iodine, leaving a lemon-yellow residue of lead oxyiodide.

Tests for Purity—Triturate 1 Gm. of the salt with 2 Gm. of ammonium chloride and 2 cc. of distilled water; a nearly white mixture results. Transfer this to a test tube and heat in a water bath for a few minutes; a clear almost colorless solution is formed (*chromate and other insoluble foreign salts*). On cooling this solution, a solid mass of nearly colorless, fine, silky crystals is produced, and on adding water or diluted sulphuric acid to this mass, yellow Lead Iodide separates.

Add 0.1 Gm. of the salt to 5 cc. of distilled water, and heat the mixture until it boils; cool the liquid and filter it into a test tube of about 40 cc. capacity, then add 5 cc. of sodium hydroxide T.S. and about 0.2 Gm. of aluminum wire; insert in the upper portion of the test tube a pledget of purified cotton, and over the mouth place a piece of moistened red litmus paper and then heat the tube on a water bath during fifteen minutes; no blue coloration of the paper will be discernible (*nitrate*).

Boil 1.5 Gm. of Lead Iodide for a few minutes with 15 cc. of distilled water, cool and filter. To 5 cc. of the filtrate add a slight excess of silver nitrate T.S., then a slight excess of hydrochloric acid and filter. Neutralize the filtrate with ammonia water and add a drop of ferric chloride T S. No red color is produced (*acetate*).

To another 5 cc. portion of the filtrate add an excess of hydrogen sulphide T.S., filter, evaporate to dryness and ignite; not more than 0.002 Gm. of residue remains.

Assay—Dry about 1 Gm. of Lead Iodide over sulphuric acid for twenty-four hours. Dissolve about 0.5 Gm. of the dried lead iodide, accurately weighed, in 30 cc. of sodium hydroxide T.S., heating on the water bath if necessary, to facilitate solution. Cool the solution, add 40 cc. of tenth-normal silver nitrate and follow it with diluted nitric acid until the solution is slightly acid, and add 15 cc. more of the nitric acid. Now titrate the excess of silver nitrate with tenth-normal potassium thiocyanate, using 3 cc. of ferric ammonium sulphate T.S., as indicator, and deduct from the volume of tenth-normal silver nitrate consumed the volume required for the chloride present in the 30 cc. of sodium hydroxide T.S. Each cc. of tenth-normal silver nitrate corresponds to 0.023047 Gm. of PbI_2.

This assay is explained on page 1463.

Preserve it in well-closed containers, protected from light.

N. F. Preparation—Unguentum Plumbi Iodidi.

Uses—Lead iodide may be given internally for glandular swelling, in doses of one to three grains (0.065 to 0.2 Gm.), but it is principally used externally in the form of a ten per cent ointment for glandular enlargements.

Antidotes—(See Part XV, on Antidotes).

PLUMBI OXIDUM RUBRUM. N. F. Red Oxide of Lead

[Plumb. Oxid. Rub.—Red Lead]

Lead orthoplumbate [Pb_2PbO_4 (685.6)] usually with some unconverted lead monoxide (PbO), corresponding to not less than 30 per cent of lead dioxide (PbO_2).

Preparation—This oxide is formed by the careful and prolonged heating of litharge (PbO) in a reverberatory or muffle furnace at from 450° to 500° C., so that it does not melt. It is also prepared by heating litharge with potassium chlorate in an oxidizing flame to a dark red heat.

Description and Physical Properties—Red Lead Oxide occurs as a heavy, orange-red powder without odor or taste. On exposure to the air it slowly absorbs moisture and carbon dioxide.

Almost insoluble in water, insoluble in alcohol, but dissolved by an excess of glacial acetic acid, also dissolved by lactic acid with the evolution of carbon dioxide and the odor of acetaldehyde.

Tests for Identity—When heated in a porcelain crucible, Red Lead Oxide at first changes color from red to a violet and then to a blackish tint, and regains its original color on cooling, but, when the heating is continued, it slowly decomposes, forming lead monoxide and oxygen. When heated in contact with charcoal, it is reduced to metallic lead.

Tests for Purity—Treat 5 Gm. of Red Lead Oxide with 50 cc. of diluted nitric acid; little effervescence results (*carbonate*), and a brown, insoluble residue of lead dioxide (PbO_2) remains, which, upon the addition of solution of hydrogen dioxide, dissolves with the evolution of oxygen, forming a colorless solution. Boil this solution for fifteen minutes, cool, and filter; the undissolved residue weighs not more than 0.1 Gm. (*silicate or lead sulphate*). On completely precipitating a portion of the solution from the foregoing test, representing 1 Gm. of Red Lead Oxide, with hydrogen sulphide, the filtrate on evaporation yields not more than 0.01 Gm. of residue.

Separate portions of the solution obtained in the last test yield with hydrogen sulphide T.S. a black precipitate; with potassium iodide T.S. a yellow precipitate; and with diluted sulphuric acid, a white precipitate; the latter two precipitates being soluble in a solution of sodium hydroxide (1 in 4).

From a solution of 0.5 Gm. of Red Lead Oxide in diluted nitric acid, obtained by the aid of solution of hydrogen dioxide, precipitate the lead with sulphuric acid and filter the mixture. After the addition of an excess of ammonia water this filtrate does not develop more than a slight, bluish tint (*copper*), nor yield more than traces of a reddish-brown precipitate (*iron*).

Heat a mixture of 1 Gm. of Red Lead Oxide with 50 cc. of distilled water to boiling, cool, and filter. The filtrate is colorless, is not more than faintly alkaline to litmus and, when evaporated to dryness, leaves not more than 0.01 Gm. of residue (*soluble impurities*).

Assay—Add about 1 Gm. of Red Lead Oxide accurately weighed, to a cool solution of 40 Gm. of crystallized sodium acetate and 2 Gm. of potassium iodide in 50 cc. of 50 per cent acetic acid, agitate the mixture until all of the Red Lead Oxide has dissolved and then titrate the solution with tenth-normal sodium thiosulphate.

Each cc. of tenth-normal sodium thiosulphate corresponds to 0.01195 Gm. of lead dioxide (PbO_2). Each Gm. of Red Lead Oxide corresponds to not less than 25.9 cc. of tenth-normal sodium thiosulphate.

This assay is explained on page 1469.

N. F. Preparations—Emplastrum Fuscum Camphoratum; Unguentum Fuscum.

Uses—It is largely used as a pigment and also in the preparation of the better grades of flint glass. Officially it is used in the N. F. in making a plaster similar to lead plaster.

LIQUOR PLUMBI SUBACETATIS DILUTUS. N.F. Diluted Solution of Lead Subacetate

(U. S. P. IX)

[**Liq. Plumb. Subacet. Dil.**—LEAD WATER]

An aqueous solution containing lead subacetate corresponding to not less than 0.70 and not more than 0.80 Gm. of Pb in each 100 cc.

	Metric	Alternative
Solution of Lead Subacetate	**35 cc.**	1 fl. oz. 58 min.
Distilled Water, recently boiled	**965 cc.**	30 fl. oz. 422 min.
To make about	**1000 cc.**	2 pints

Mix them.

Diluted Solution of Lead Subacetate is a colorless liquid, usually showing a slight turbidity; it has a sweet, astringent taste, and an alkaline reaction.

A white precipitate is formed when 5 cc. of the Solution is mixed with 5 cc. of mucilage of acacia.

Separate portions of Diluted Solution of Lead Subacetate diluted with 5 volumes of recently boiled, distilled water, yield a black precipitate with hydrogen sulphide T.S., a yellow precipitate with potassium iodide T.S., a white precipitate with diluted sulphuric acid, and a white precipitate, tinged with neither red nor blue, with potassium ferrocyanide T.S.

Assay—Transfer 50 cc. of the Solution, accurately measured, to a 200 cc. measuring flask, dilute with 50 cc. of recently boiled, distilled water, then add 50 cc. of tenth-normal oxalic acid and agitate the mixture thoroughly for five minutes. Add enough distilled water to make 200 cc., filter, rejecting the first 20 cc. of filtrate, add 5 cc. of sulphuric acid to 100 cc. of the subsequent filtrate, warm to about 70° C. and titrate with tenth-normal potassium permanganate.

Each cc. of tenth-normal oxalic acid corresponds to 0.01036 Gm. of Pb.

This assay is explained on page 1473.

Preserve this Solution in small, well-filled and tightly stoppered bottles.

Uses—Lead water is used as a soothing application in irritation of the skin.

Antidotes—(See Part XV, on Antidotes).

Unofficial Salts and Preparations of Lead

Plumbi Bromidum, $PbBr_2$ Lead Bromide	White, shining needles that darken on exposure to sunlight. It can be made by precipitation from solutions of lead acetate and potassium bromide. Lead bromide is insoluble in water
Lead Carbonate White Lead, Flake White	A mixture of lead carbonate and hydroxide, approximately $(PbCO_3)_2$ $Pb(OH)_2$. A heavy, white, opaque powder, or a pulverulent mass without odor or taste, permanent in the air. Insoluble in water or in alcohol. Largely used in the arts, especially in paints. Its external use is dangerous, producing lead poisoning and it should not be used in face powders
Plumbi Chloridum, $PbCl_2$ Lead Chloride	A white, crystalline powder, insoluble in cold water. It is of analytical interest and is used in preparing other salts of lead
Plumbi Chromas, $PbCrO_4$ Lead Chromate	Commonly called *chrome yellow* and *Leipzig yellow*. Yellow crystals or yellow crystalline powder; insoluble in water. It is made by precipitation from solutions of a soluble salt, and a soluble chromate, and is largely used as a pigment
Plumbi Dioxidum, PbO_2 Lead Dioxide	A brown, crystalline powder; insoluble in water. It must be stored and shipped with caution because of its strong oxidizing action. It is used in the manufacture of salts of lead
Plumbi Hydroxidum, $Pb(OH)_2$ Lead Hydroxide	A white powder, slightly soluble in water. Like other soluble lead compounds it is poisonous. It is used in the manufacture of salts of lead
Plumbi Nitras, $Pb(NO_3)_2$ Lead Nitrate	Colorless crystals or a white, crystalline powder; readily soluble in water. Lead nitrate is largely used in the manufacture of other lead compounds, and in the preparation of mordants, pigments, and matches
Plumbi Saccharas Lead Saccharate	A white powder, insoluble in cold water. This compound is of little importance but has been used in medicine
Plumbi Sulphas, $PbSO_4$ Lead Sulphate	A white, crystalline powder; insoluble in cold water and slightly soluble in hot water. It forms an insoluble coating in lead pipes that are used for conducting tap water which contains sulphates. Because of its insolubility and permanence it is used in paints

Copper, Cu; 63.57

The word *copper* comes from the Latin word "cuprum" which in turn is corrupted from the Latin "aes cyprium" alluding to Cyprus, the Roman source of the element, in the time of Pliny. It is found naturally in its metallic

condition, but chiefly in combination as sulphide or oxide. It is also found as sulphate, carbonate, phosphate, or arsenate. It is a brilliant metal, of a red color, having a specific gravity of 8.92 to 8.95. It forms two oxides: red cuprous oxide, Cu_2O and black cupric oxide, CuO.

Tests for Compounds of Copper

Solutions of copper compounds acidulated with hydrochloric acid deposit a red film of metallic copper upon a bright, untarnished surface of metallic iron. An excess of ammonia T.S. added to a solution of a copper salt produces a blue color. With potassium ferrocyanide T.S. solutions of cupric salts yield a red precipitate.

CUPRI SULPHAS. U. S. Cupric Sulphate

[Cupr. Sulph.—Copper Sulphate]

Cupric Sulphate contains not less than 63 per cent and not more than 66.8 per cent of $CuSO_4$ (159.63), corresponding to not less than 98.5 per cent of the crystallized salt [$CuSO_4.5H_2O = 249.71$].

Preparation—This salt is economically made by acting on scrap copper with diluted sulphuric acid, heating, evaporating the solution, and crystallizing.

Oxygen of the air assists in changing the copper into sulphate. The reaction may be expressed as follows:

$$\underset{\text{copper}}{2Cu} + \underset{\text{sulphuric acid}}{2H_2SO_4} + \underset{\text{oxygen}}{O_2} = \underset{\text{copper sulphate}}{2CuSO_4} + \underset{\text{water}}{2H_2O}$$

In another largely used process the scrap copper is heated in a reverberatory furnace with sulphur, the reaction being controlled in order to obtain a maximum yield of sulphate. The mass is then thrown into diluted sulphuric acid and any unchanged oxide, sulphide, or metal is converted into copper sulphate.

Description and Physical Properties—Deep blue, triclinic crystals or a blue, granular powder. It is odorless, and has a nauseous, metallic taste. It is slowly efflorescent in dry air.

One Gm. of Cupric Sulphate is soluble in 2.5 cc. of water, 500 cc. of alcohol, and in 2.8 cc. of glycerin, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water.

Tests for Identity—When heated to 30° C., Cupric Sulphate loses part of its water of crystallization and is converted into a pale blue, amorphous powder. More water is lost at 100° C. and finally at 200° C. a white, anhydrous powder remains. At a still higher temperature, sulphur dioxide and oxygen are given off, and a residue of black cupric oxide remains.

An aqueous solution of the salt (1 in 20) has a blue color, and is acid to litmus paper.

An aqueous solution of the salt (1 in 10) responds to the reactions for copper, page 743, and for sulphates, page 581.

Test for Purity—Dissolve 1 Gm. of Cupric Sulphate in 50 cc. of distilled water, add 1 cc. of diluted hydrochloric acid, and pass hydrogen sulphide through the solution until all of the copper is precipitated: upon evaporating the filtrate and igniting, the weight of the residue does not exceed 0.003 Gm. (*other metals*).

Assay—Dissolve about 1 Gm. of Cupric Sulphate, accurately weighed, in 50 cc. of distilled water, add 4 cc. of acetic acid and 3 Gm. of potassium iodide, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.01596 Gm. of $CuSO_4$.

Cupric Sulphate may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1466.

Preserve in well-closed containers.

N. F. Preparation—Mistura Adstringens.

Uses—Copper sulphate, called commercially *bluestone* or *blue vitriol*, is used internally as an emetic, in doses of four grains (0.25 Gm.); as an astringent or tonic, from one-fifth to one-half grain (0.01 to 0.03 Gm.) is given. It is used as an injection in gonorrhea and other diseases, and also as a

stimulant wash, and in substance as an escharotic. It is also antidotal to phosphorus.

Under the name "*Cupricsticks*", the Tappan-Zee Surgical Company offer small wooden sticks tipped with a mixture containing 25 per cent copper sulphate, combined with alum and potassium nitrate. They are for local application as a styptic, each stick to be used but once.

Antidotes—(See Part XV, on Antidotes).

Unofficial Salts of Copper

Cupric Ammonium Sulphate, $CuSO_4.4NH_3.H_2O$	A dark blue, crystalline powder; soluble in water, forming a deep blue solution. It is used in calico printing and in the manufacture of other copper compounds
Cupric Acetate, $Cu(C_2H_3O_2)_2 + H_2O$	A greenish-blue powder. It is soluble in water and is used in the production of insecticides, textiles, and ceramics. It has also been used in medicine. It is poisonous
Cupric Arsenate, $Cu_3As_2O_8 + 4H_2O$	A bluish-green, amorphous powder; insoluble in water. It is poisonous and is used as an insecticide and as a pigment
Cupric Bromide, $CuBr_2$	Dark, lustrous crystals resembling iodine; very soluble in water, deliquescent. It is converted into cuprous bromide by heat, with the liberation of bromine. This compound is of little importance
Cupric Chloride, $CuCl_2 + 2H_2O$	Greenish-blue, deliquescent crystals; very soluble in water. It is used in sympathetic ink, as a mordant, as an oxidizing agent, and in the production of certain aniline dyes
Cupric Citrate (N. N. R., 1925)	A green or bluish-green, crystalline powder; sparingly soluble in water; readily soluble in a solution of an alkali citrate. It is used in medicine as an astringent and antiseptic. Copper citrate is more fully described in the New and Non-official Remedies of 1925
Cupric Nitrate, $Cu(NO_3)_2$	Blue, deliquescent crystals; readily soluble in water. It is used in the manufacture of other copper compounds, also in dyeing, and in calico printing
Cupric Oxide, CuO	A brownish-black, amorphous powder; insoluble in water. It is used as an oxidizing agent in analytical chemistry and to impart green and blue colors to glass, porcelain, and stoneware
Cupric Subacetate, $Cu(OH)_2.Cu(C_2H_3O_2)_2$ Verdigris	A poisonous, greenish-blue powder; soluble in water. It is used as an insecticide, as a pigment, and in dyeing and printing fabrics
Cupric Tartrate	This salt is present in the well-known Fehling's solution which is an alkaline solution of cupric tartrate (see page 1554). Cupric tartrate is of very little importance otherwise
Cuprous Bromide, Cu_2Br_2	A brown, crystalline mass, made by boiling a solution of cupric bromide with copper. It is of very little importance
Cuprous Chloride, Cu_2Cl_2	A yellowish, crystalline mass; insoluble in cold water. It forms several addition compounds with ammonia and its ammoniacal solution reacts with acetylene to form the explosive *cuprous acetylide*
Cuprous Iodide, Cu_2I_2	The only known iodide of copper. A white powder; practically insoluble in water. This interesting compound offers a means of separating iodides from bromides and chlorides, since cuprous iodide is precipitated when copper sulphate solution is added to a mixture of all three salts in solution
Cupric Fluoride, CuF_2	A blue, crystalline substance; soluble in water; poisonous. It is used in ceramics and in enamels

Silver, Ag; 107.88

The word *silver* is derived from a Greek word referring to the brightness of the metal. It is found in the metallic state, but usually as a sulphide, sometimes associated with lead sulphide, or *galena*. Its sulphide also occurs abundantly as *argentite* or *silver glance*. Its Latin name is *argentum*.

Silver is a brilliant white metal, very malleable and ductile, having a specific gravity of 10.4 to 10.6 and melting at 960° C. It forms but one oxide, Ag_2O.

Tests for Silver Salts

Solutions of silver salts yield with hydrochloric acid a white, curdy precipitate, which is insoluble in nitric acid but is easily soluble in ammonia T.S.

Protein and Colloidal Combinations of Silver, Etc.

These combinations of silver do not possess the caustic action of silver salts of mineral acids, but retain the germicidal and antiseptic action, although in a less degree. They are described under the organic combinations of silver, page 874.

ARGENTI NITRAS. U. S. Silver Nitrate

[Arg. Nit.]

Silver Nitrate, when finely powdered and dried to constant weight in the dark over sulphuric acid, contains not less than 99.8 per cent of $AgNO_3$ (169.89).

Preparation—Mix 3 parts of metallic silver with 10 parts of nitric acid (25 per cent HNO_3) in a large porcelain dish and warm the mixture until the reaction begins. Invert a funnel over the liquid to prevent it from spurting, and, when the silver is dissolved, rinse the sides of the funnel with a little distilled water. Filter the solution through glass wool, if necessary, and evaporate it on a sand bath to dryness. Then raise the temperature until the salt melts and the nitrous fumes escape, which will soon occur if the silver is pure. If copper is present, as it is likely to be if coin has been used as the source of silver, it being recognized by the bluish color of the solution, it requires longer heating and the reaction is complete when gas no longer escapes and the mass becomes black from the formation of copper oxide. The fused mass is then dissolved in twice its weight of water, filtered, and set aside to crystallize. The reaction is indicated by the following equation:

$$\underset{\text{silver}}{3Ag} + \underset{\substack{\text{nitric}\\\text{acid}}}{4HNO_3} = \underset{\substack{\text{silver}\\\text{nitrate}}}{3AgNO_3} + \underset{\substack{\text{nitric}\\\text{oxide}}}{NO} + \underset{\text{water}}{2H_2O}$$

Description and Physical Properties—Colorless, odorless, transparent, tabular, rhombic crystals, becoming gray or grayish-black on exposure to light in the presence of organic matter.

One Gm. of Silver Nitrate is soluble in 0.4 cc. of water and in 30 cc. of alcohol, at 25° C. One Gm. is soluble in slightly more than 0.1 cc. of boiling water and in 6.5 cc. of boiling alcohol. It is slightly soluble in ether.

When heated in a porcelain crucible to about 200° C., Silver Nitrate melts, forming a faintly yellow liquid, which on cooling, congeals to a pure white, crystalline mass. At a higher temperature it gradually decomposes with the evolution of nitrogen oxides.

Tests for Identity—An aqueous solution of the salt (1 in 50) responds to the reactions for silver, page 744.

Mix an aqueous solution of the salt (1 in 10) in a test tube with a drop of diphenylamine T.S. and then carefully superimpose it upon sulphuric acid: a deep blue color appears at the line of contact.

Tests for Purity—An aqueous solution of the salt (1 in 10) is clear and colorless, and is neutral to litmus paper.

An aqueous solution of the salt (1 in 10) is not colored even faintly blue by the addition of an excess of ammonia T.S. (*copper*).

Assay—Dissolve about 0.8 Gm. of finely powdered Silver Nitrate, previously dried in the dark over sulphuric acid and accurately weighed, in 5 cc. of distilled water. Add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01699 Gm. of $AgNO_3$.

Silver Nitrate may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1462.

Preserve in dark amber-colored, glass-stoppered vials, protected from light.

Preparation—Argenti Nitras Fusus.

History—This salt was described by Geber in the seventh century A.D. It was first used in medicine in the eighteenth century in Pilulæ Lunares. Christopher Glaser, the apothecary to Louis XIV of France, first prepared it in sticks for use as a caustic.

Uses—Silver nitrate is used externally as a caustic and germicide. In dilute solution it is valuable for its astringent and disinfectant powers and is widely employed as a local application to inflamed mucous membranes as well as wounds. Internally, it is given in gastritis and diarrhea, in doses of one-fifth to one-half grain (0.01 to 0.03 Gm).

Antidotes—(See Part XV, on Antidotes).

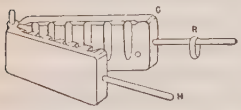
ARGENTI NITRAS FUSUS. U. S. Fused Silver Nitrate

[**Arg. Nit. Fus.**—Molded Silver Nitrate, Lunar Caustic]

Fused Silver Nitrate contains not less than 94.5 per cent of $AgNO_3$(169.89).

The official process for making this preparation has been deleted. It was formerly made by fusing silver nitrate with the addition of hydrochloric acid, added in small proportions to produce a small amount of silver chloride, which had the effect of toughening the fused mass and making the sticks less brittle. E. J. Hughes found that when a small proportion of sodium chloride was used instead of the hydrochloric acid, the process was very much improved, and the preparation was equally efficient.

Fig. 431



Caustic cone mold

In order to keep the sticks from becoming discolored during the molding process, it is advisable to add a little diluted nitric acid (1 in 5) occasionally to the melted nitrate, and carefully prevent the mass from becoming overheated. Fig. 431 illustrates the silver molds used in molding the cones.

Description and Physical Properties—A white, hard, odorless solid, generally in the form of pencils or cones, showing a fibrous fracture and becoming gray or grayish-black on exposure to light.

Fused Silver Nitrate, with the exception of about 5 per cent which is silver chloride, possesses the solubility described under *Argenti Nitras*.

Tests for Identity and Purity—A filtered, aqueous solution of Fused Silver Nitrate (1 in 10) is neutral to litmus paper, and conforms to the tests for identity and purity under *Argenti Nitras*.

Assay—Add about 0.8 Gm. of Fused Silver Nitrate, accurately weighed, to 50 cc. of distilled water, and, when the silver nitrate has dissolved, filter the solution. Thoroughly wash the filter and sediment with distilled water, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. to the mixed filtrate and washings, and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01699 Gm. of $AgNO_3$.

Fused Silver Nitrate may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1462.

Preserve in dark, amber-colored, glass-stoppered vials, protected from light.

Uses—Fused silver nitrate is used as an escharotic and germicide, especially for small septic wounds and ulcers. A good caustic holder may be made from a glass stirring rod of the same diameter as the cone by joining it to the cone with a short length of rubber tubing. The cone may be protected from the action of the air by slipping over it another short length of rubber tubing, having a very short piece of glass rod in the other end as a stopper.

Death has resulted more than once through the careless use of silver nitrate in cauterizing the throat, the cone having slipped out of the fingers and then been swallowed by the patient.

The Tappan-Zee Surgical Company offer small wooden sticks, with the tip dipped in 75 per cent fused silver nitrate, for application as a local caustic. They are called "*causticks*". Each stick is to be used for a single treatment.

Antidotes—(See Part XV, on Antidotes).

Unofficial Salts of Silver

Argenti Acetas, $AgC_2H_3O_2$ Silver Acetate	A white, crystalline salt; slightly soluble in water, freely soluble in hot water. It has been used in medicine
Argenti Bromidum, AgBr Silver Bromide	A pale yellow, crystalline powder, darkening on exposure to light. Only very slightly soluble in water but readily soluble in solutions of potassium bromide, potassium cyanide, or sodium thiosulphate. Its chief use is in photography
Argenti Chloridum, AgCl Silver Chloride	A white, granular powder that darkens on exposure to light. Practically insoluble in water but dissolved by ammonia water or by solutions of potassium cyanide and by sodium thiosulphate. It is of analytical interest as the product of the well-known identity test for silver salts in solution. It is used in silver plating and in photography
Argenti Chromas, Ag_2CrO_4 Silver Chromate	A red, crystalline powder, practically insoluble in water. The pink to red color that appears when potassium chromate is used as an indicator, in the presence of silver nitrate, is due to the formation of this compound
Argenti Citras, $Ag_3C_6H_5O_7$ (N. N. R.) Silver Citrate	Dry, white, crystalline needles or powder; difficultly soluble in water. It is used in medicine as a non-irritating antiseptic, applied directly to wounds, and in 1 to 4000 to 1 to 10,000 solutions for urethral injections
Argenti Cyanidum, AgCN (U. S. P. VIII) Silver Cyanide	A very poisonous white powder that darkens on exposure to light. It is insoluble in water, potassium cyanide solution, and in sodium thiosulphate solution. It is used in medicine and in silver plating. At one time used in the extemporaneous preparation of hydrocyanic acid, see page 991
Argenti Nitras Mitigatus Mitigated Silver Nitrate	A diluted form of silver nitrate made by fusing together thirty parts of silver nitrate and sixty parts of potassium nitrate. Its chief use is as a caustic
Argenti Iodidum, AgI Silver Iodide	A yellow powder that darkens on exposure to light. It is insoluble in water but dissolves readily in hydriodic acid, potassium iodide, potassium cyanide, and sodium thiosulphate solutions. It is chiefly used in medicine and in photography. Silver iodide is made by double decomposition between potassium iodide and silver nitrate solutions and is largely used as a suspension in gelatin solution, acacia, tragacanth, Irish moss, or other mucilage, in a strength of from 2 to 5 per cent
Argenti Lactas, N. N. R., $AgC_3H_5O_3 + H_2O$ Silver Lactate	This salt is made by boiling silver carbonate with lactic acid and collecting and drying the precipitate. It is soluble in water and is used in medicine as an antiseptic. Silver lactate is more fully described in the New and Non-official Remedies of 1925
Argenti Oxalas, $Ag_2C_2O_4$ Silver Oxalate	A sparingly soluble, white salt, made by precipitation of silver nitrate by a soluble oxalate. It is easily decomposed by heat, yielding metallic silver
Argenti Oxidum, Ag_2O (U. S. P. IX) Silver Oxide	A heavy, brownish-black powder, easily reduced by exposure to light. It is very slightly soluble in water to which it imparts an alkaline reaction. Silver oxide is of no medicinal value although it was formerly employed in chronic nervous diseases
Argenti Phosphas, Ag_3PO_4 Silver Phosphate	A yellow powder, turning brown on exposure to light. It is only very slightly soluble in water, and is used in certain photographic emulsions instead of the nitrate
Argenti Sulphas, Ag_2SO_4 Silver Sulphate	A white, crystalline powder; only sparingly soluble in cold water. This salt is of little importance, but a considerable amount of it has been produced in separating silver from gold, by means of concentrated sulphuric acid

Mercury, Hg; 200.6

The name *mercury* comes from the mythological Mercury, the messenger of the gods. The ancient chemists symbolized the metal by the sign used for the planet Mercury. It is frequently called quicksilver and is found most abundantly as sulphide, or *cinnabar;* the principal mines are in Spain and California. The native metal is also occasionally found in tiny globules. It is a brilliant, silver-white metal, liquid above $-38.8°$ C. and having the specific gravity 13.596. In addition to the two main series of compounds, namely, the *mercurous* and *mercuric*, mercury forms a variety of chemical combinations of a complex nature. It is used more largely in medicine in the metallic state than any other element.

Tests for Compounds of Mercury

Solutions of mercury salts free from excess of nitric acid, when applied to bright copper foil, yield a deposit, which, upon rubbing, becomes bright and

silvery in appearance. With an excess of hydrogen sulphide, mercury compounds yield a black precipitate which is insoluble in ammonium sulphide T.S. or in boiling diluted nitric acid.

Mercuric compounds in solution yield a yellow precipitate with sodium hydroxide T.S. They also yield in neutral solutions a scarlet precipitate with potassium iodide T.S. This precipitate is very soluble in an excess of potassium iodide T.S.

Mercurous compounds are blackened by ammonia T.S. and by sodium hydroxide T.S. Solutions of mercurous salts yield with hydrochloric acid a white precipitate which is blackened by ammonia T.S. With potassium iodide T.S. a yellow precipitate is produced.

HYDRARGYRUM. U.S. Mercury

[**Hydrarg.**—QUICKSILVER]

Mercury contains not less than 99.5 per cent of Hg (200.6).

Mercury for pharmaceutical uses should be pure. To separate mechanical impurities, moisture, or small quantities of oxide, mercury may be filtered by collecting it in a clean piece of chamois leather and, gathering the corners together, forcibly squeezing the particles through the pores of the leather. Mercury is also purified chemically by allowing it to descend in tiny drops through a column of diluted nitric acid. This treatment removes any baser metals that may be present and does not seriously attack the mercury, but distillation is preferable in most cases to purify the metal effectually. This may be accomplished by a process formerly official in the British Pharmacopœia, as follows:

"Take of mercury, 3 pounds [avoirdupois]; hydrochloric acid, 3 fluidrachms; distilled water, a sufficiency. Place the mercury in a glass retort or iron bottle, and, applying heat, cause two pounds and a half of the metal to distil over into a flask employed as a receiver. Boil on this for five minutes the hydrochloric acid diluted with 9 fluidrachms of distilled water, and having, by repeated affusions of distilled water and decantations, removed every trace of acid, let the mercury be transferred to a porcelain capsule, and dried first by filter paper, and finally on a water bath."

Description and Physical Properties—A shining, silver-white metal, liquid at ordinary temperatures and easily divisible into spherical globules. When cooled to about −40° C., it forms a ductile, malleable mass.

Tests for Identity—Specific gravity: about 13.5 at 25° C.

Mercury is insoluble in the ordinary solvents, in concentrated hydrochloric acid, and at ordinary temperatures, in sulphuric acid, but it dissolves in the latter when boiled with it. It is readily and completely dissolved by nitric acid.

Mercury boils at about 358° C.

Tests for Purity—When volatilized at about 300° C., Mercury yields not more than 0.02 per cent of residue.

When globules of Mercury are dropped upon white paper, they roll about freely, retaining their globular form and leaving no streaks or traces.

Mercury should present a bright surface, even after agitation in contact with air.

Assay—Dissolve about 0.4 Gm. of Mercury, accurately weighed, in a mixture of 10 cc. of distilled water and 10 cc. of nitric acid, warm the solution gently until red fumes cease to be evolved and the solution is colorless, and add 150 cc. of distilled water. Then add 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate until a permanent reddish color is produced. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01003 Gm. of Hg.

Mercury may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1461.

Preserve in strong, well-closed containers.

U. S. P. Preparations—Hydrargyrum cum Creta; Massa Hydrargyri; Unguentum Hydrargyri Fortius; Unguentum Hydrargyri Mite (from Mercurial Ointment).

N. F. Preparations—Petroxolinum Hydrargyri; Unguentum Hydrargyri Nitratis.

History—This metal was known to the peoples of very ancient times. Compounds of mercury, however, were first prepared and described by Geber in the seventh century A.D. Among these were red precipitate and corrosive sublimate.

Uses—Mercury, in bulk, is used only for pharmaceutical purposes in preparing blue mass, gray powder, mercurial ointment, etc.

MASSA HYDRARGYRI. U.S. Mass of Mercury

[Mass. Hydrarg.—Blue Mass, Blue Pill]

Mass of Mercury contains not less than 32 per cent and not more than 34 per cent of Hg (200.6). The formula will be found on page 488.

Assay—Place about 0.5 Gm. of Mass of Mercury, accurately weighed and rolled into one or two pills, in a Kjeldahl flask of about 300 cc. capacity. Add 10 cc. of sulphuric acid, and heat on a water bath during ten minutes, gently agitating at frequent intervals to disintegrate the mass. Insert a small funnel in the neck of the flask, and slowly add 10 cc. of nitric acid. Heat the mixture with a Bunsen burner, at first gently, gradually increasing the heat until the solution is colorless or only slightly yellow, adding more nitric acid if necessary, and keep the funnel in the neck of the flask during heating. Allow the solution to cool sufficiently, and add carefully through the funnel about 30 cc. of distilled water, rinsing the stem of the funnel with a few cc. of distilled water and allowing the rinsings to run into the flask. Then add potassium permanganate T.S. to the warm solution, until a slight pink color persists. Cool the solution, discharge its color by the addition of just sufficient oxalic acid T.S., add 3 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate to a permanent reddish color. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01003 Gm. of Hg.

This assay is explained on page 1462.

N. F. Preparations—Pilulæ Aloes, Hydrargyri et Podophylli; Pilulæ Digitalis, Scillæ et Hydrargyri.

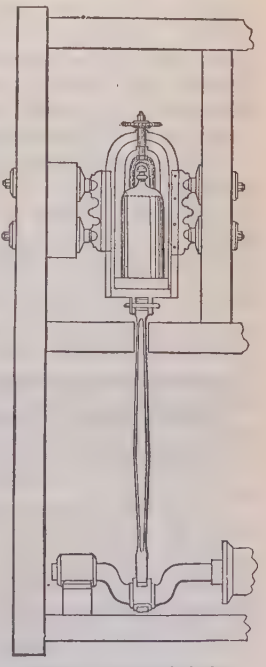
By using the official formula the pharmacist is enabled to make blue mass extemporaneously with very little labor. The mass should not be *forcibly pressed*, or the globules of mercury will run together, and will grow larger instead of smaller. The mercury is best distributed by a rapid, beating motion.

History—The first pills containing metallic mercury were introduced into European medicine by Barbarossa, a famous Algerian pirate, who sent the formula to Francis I, of France, about the middle of the sixteenth century.

Uses—The object of this preparation is to furnish mercury in a finely divided condition. It is used chiefly as a purgative and is supposed to possess cholagogic powers.

Dose—five to ten grains (0.39 to 0.6 Gm.).

Fig. 432



Squibb's mercurial shaker

Fig. 432 illustrates the mercurial shaker invented by Doctor Squibb. It consists of a stout wooden frame to which is attached a metal cage for holding a strong glass gallon bottle; this is held in place by a cup-shaped screw clamp which rests on a cloth collar placed around the top of the bottle above the shoulder; the sides of the cage move in guides which are bolted to the wooden frame. A vertical shaft operated by the horizontal shaft at the bottom communicates an "up and down" motion to the bottle, and, when speeded properly, the mercury and a mixture containing honey in the bottle is thrown back and forth from the top to the bottom rapidly, and the mercury is thus quickly extinguished. The mixture is afterwards incorporated with the powders, placed

in a large vessel and the mass is finished. In making mercurial ointment, the mercury is placed in the bottle holding the lard, and both are shaken together; the mixture is afterwards incorporated with the melted suet. This process of extinguishing mercury is termed "succussion".

Pot mills (Fig. 230) are also used on a manufacturing scale for extinguishing Mercury in making both the mass and the ointment.

HYDRARGYRUM CUM CRETA. U.S. Mercury with Chalk

[**Hydrarg. c. Cret.**—Gray Powder]

Mercury with Chalk contains not less than 37 per cent and not more than 39 per cent of Hg.

	Metric	Alternative
Mercury	**38 Gm.**	166 gr.
Honey	**10 Gm.**	44 gr.
Prepared Chalk	**57 Gm.**	249 gr.
Water, a sufficient quantity,		
To make	**100 Gm.**	1 oz. av.

Weigh the mercury and honey successively into a strong bottle of the capacity of 100 cc. [1 fl. oz.] and add 2 cc. [10 min.] of water. Cork the bottle, and shake it for about half an hour at a time until the aggregate time of shaking reaches ten hours, or until the globules of mercury are no longer visible under a lens magnifying four diameters. The shaking may be more conveniently performed by mechanical means. Rub the prepared chalk with water in a mortar to a thick, creamy paste, and, having added the contents of the bottle, wash out the last portions with a little water, and triturate the whole to a uniform mixture. Finally dry the mixture, first between ample layers of bibulous paper, and afterwards in a dish at the ordinary temperature until it weighs 100 Gm. [1 oz. av.]. Then reduce it to a uniform powder without trituration.

The intention here is to furnish mercury in a finely divided condition in the form of a powder. The above process is a very tedious one. In Matter's process, fifty-three grains of powdered acacia are mixed with fifty-three grains of chalk, enough water added to form a thin paste, and one hundred and sixty-six grains of mercury added and triturated until extinguished. One hundred and sixty-six grains of chalk are made into a paste with water, and added to it, and the water evaporated from the mixture in a water bath; it is rubbed to powder when dry.

Description and Physical Properties—A light gray, rather damp powder, free from grittiness. It is odorless, and has a slightly sweet taste.

Test for Identity—Digest 0.1 Gm. of the powder with 20 cc. of warm acetic acid. The chalk dissolves with effervescence, and a residue of finely divided mercury remains.

Tests for Purity—On filtering the mixture obtained in the preceding test, the filtrate becomes not more than slightly opalescent on the addition of a few drops of hydrochloric acid (*mercurous oxide*).

Digest 0.1 Gm. of the powder with 20 cc. of warm diluted hydrochloric acid, and filter; the filtrate is not rendered more than slightly brown by hydrogen sulphide T.S. (*mercuric oxide*).

Assay—Dissolve about 1 Gm. of Mercury with Chalk, accurately weighed, in a mixture of 10 cc. of distilled water and 10 cc. of nitric acid, and heat on a water bath until red fumes cease to be evolved and the liquid becomes colorless. Then add 150 cc. of distilled water and 2 cc. of ferric ammonium sulphate T.S. and titrate the solution with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01003 Gm. of Hg.

Mercury with Chalk may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1462.

Preserve in well-closed containers, protected from light.

Uses—Mercury with chalk is a mild mercurial cathartic, frequently given to children. In small doses it is occasionally used as an antisyphilitic. It should be free from mercurous or mercuric oxide; through exposure to air old specimens frequently contain both. The dose is four grains (0.25 Gm.).

HYDRARGYRUM AMMONIATUM. U. S. Ammoniated Mercury

[**Hydrarg. Ammon.**—White Precipitate, Mercurammonium Chloride]

Ammoniated Mercury contains $HgNH_2Cl$ (252.08), corresponding to not less than 78 per cent and not more than 80 per cent of Hg (200.6).

Preparation—The U. S. P. X does not include the process for the manufacture, but the U. S. P. VIII process was as follows:

Dissolve 100 Gm. [1 oz. av.] of corrosive mercuric chloride in 2000 cc. [20 fl. oz.] of warm distilled water, filter the solution, and allow it to cool. Pour the filtered liquid gradually, and with constant stirring, into 150 cc. [1½ fl. oz.] of ammonia water, taking care that the latter shall remain in slight excess. Collect the precipitate on a filter, and, when the liquid has drained from it as much as possible, wash it with a mixture of 400 cc. [4 fl. oz.] of distilled water and 20 cc [1½ fl. dr.] of ammonia water. Finally, dry the precipitate between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C., and keep it in well-stoppered bottles, protected from light.

In this process the ammonium of one-half of the ammonium chloride, which is formed upon mixing the solutions, has two of its hydrogen atoms replaced by one atom of bivalent mercury, NH_4Cl becoming NH_2HgCl.

$$\underset{\text{mercuric chloride}}{HgCl_2} + \underset{\text{ammonia water}}{2NH_4OH} = \underset{\text{ammonium chloride}}{NH_4Cl} + \underset{\text{mercurammonium chloride}}{NH_2HgCl} + \underset{\text{water}}{2H_2O}$$

Description and Physical Properties—White, pulverulent pieces, or a white, amorphous powder. It is odorless, and is stable in the air.

Ammoniated Mercury is insoluble in water and in alcohol. By prolonged washing with water, it is gradually decomposed, assuming a yellow color and becoming converted into a basic salt. It is readily soluble in warm hydrochloric, nitric, and acetic acids and in a cold solution of ammonium carbonate. One Gm. is completely soluble in a cold solution of 5 Gm. of sodium thiosulphate in 5 cc. of water, with the evolution of ammonia. When the latter solution is heated for a short time, red mercuric sulphide is precipitated which upon protracted boiling turns black.

Tests for Identity—At a temperature below a red heat Ammoniated Mercury is decomposed without fusion, and at a red heat it is volatilized.

When heated with sodium hydroxide T.S., Ammoniated Mercury turns yellow, with the evolution of ammonia.

A solution of Ammoniated Mercury in diluted nitric acid yields with potassium iodide T.S. a red precipitate, soluble in an excess of the reagent. The nitric acid solution yields a white precipitate with silver nitrate T.S.

Tests for Purity—When volatilized at about 300° C., Ammoniated Mercury leaves not more than 0.2 per cent of residue.

Ammoniated Mercury is completely soluble in warm hydrochloric acid (*mercurous salts*) without effervescence (*carbonates*).

Assay—Dissolve about 0.5 Gm. of Ammoniated Mercury, accurately weighed, in 2 cc. of hydrochloric acid and 10 cc. of distilled water, warming gently until solution is effected, then dilute with 300 cc. of distilled water, and proceed as directed under *Hydrargyri Chloridum Corrosivum*, page 752, beginning with the word "Pass" in the third line of the assay. The weight of mercuric sulphide obtained, multiplied by 0.862, indicates its equivalent in mercury (Hg). Each Gm. of Ammoniated Mercury corresponds to not less than 0.9047 Gm. and not more than 0.9279 Gm. of mercuric sulphide.

Ammoniated Mercury may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1479.

Preserve in well-closed containers, protected from light.

U. S. P. Preparation—Unguentum Hydrargyri Ammoniati.

History—White precipitate was first described by Beguin, a chemist and writer, in 1632. A soluble double chloride of mercury and ammonium was known to the alchemists by the names *sal alembroth* and *sal sapientiæ*.

Uses—This compound of mercury is not used internally; it is applied externally in the form of ointment chiefly in cutaneous affections. It is a frequently used ingredient in proprietary freckle-removing creams and skin bleaches, many of which are dangerous for indiscriminate use.

HYDRARGYRI CHLORIDUM CORROSIVUM. U. S. Corrosive Mercuric Chloride

[**Hydrarg. Chlor. Corr.**—Bichloride of Mercury, Corrosive Sublimate, Mercuric Chloride, Perchloride of Mercury]

Corrosive Mercuric Chloride, when dried to constant weight over sulphuric acid, contains not less than 99.5 per cent of $HgCl_2$ (271.52).

Preparation—This important mercuric salt may be made by the former official process, as follows:

Take of mercury, 24 oz.; sulphuric acid, 36 oz.; sodium chloride, 18 oz. Boil the mercury with the sulphuric acid, by means of a sand bath, until a dry, white mass remains. Rub this, when cold, with the sodium chloride in an earthenware mortar; then sublime the mixture with a gradually increasing heat.

By boiling sulphuric acid in excess with mercury to dryness, a white salt (mercuric sulphate) is formed, according to the reaction:

$$\underset{\text{sulphuric acid}}{2H_2SO_4} + \underset{\text{mercury}}{Hg} = \underset{\text{mercuric sulphate}}{HgSO_4} + \underset{\text{sulphur dioxide}}{SO_2} + \underset{\text{water}}{2H_2O}$$

When this is mixed with sodium chloride, and the mixture exposed to a subliming heat, decomposition takes place, according to the reaction:

$$\underset{\text{mercuric sulphate}}{HgSO_4} + \underset{\text{sodium chloride}}{2NaCl} = \underset{\text{sodium sulphate}}{Na_2SO_4} + \underset{\text{mercuric chloride}}{HgCl_2}$$

The mercuric chloride thus formed sublimes, and the sodium sulphate remains.

Description and Physical Properties—Heavy, colorless, odorless, rhombic crystals, or crystalline masses, or a white powder.

Caution—Corrosive Mercuric Chloride is extremely poisonous.

One Gm. of Corrosive Mercuric Chloride is soluble in 13.5 cc. of water, 3.8 cc. of alcohol, about 12 cc. of glycerin, and in 22 cc. of ether, at 25° C. One Gm. is soluble in 2.1 cc. of boiling water and in 1.6 cc. of boiling alcohol.

The salt fuses to a colorless liquid at about 265° C., and at about 300° C. volatilizes as a dense, white vapor.

Tests for Identity—An aqueous solution of Corrosive Mercuric Chloride (1 in 20) is acid to litmus paper, but becomes neutral upon the addition of sodium chloride.

An aqueous solution of the salt (1 in 20) responds to the reactions for mercuric compounds, page 747, and for chlorides, page 567.

Tests for Purity—When volatilized at about 300° C., Corrosive Mercuric Chloride leaves not more than 0.1 per cent of residue.

Not more than 0.5 per cent of residue remains on dissolving finely powdered Corrosive Mercuric Chloride in ether or alcohol.

Assay—Dry about 0.5 Gm. of Corrosive Mercuric Chloride to constant weight over sulphuric acid, weigh accurately, and dissolve in 300 cc. of warm water to which 1 cc. of hydrochloric acid has been added. Pass hydrogen sulphide through the cold solution until saturated, when the precipitate of mercuric sulphide readily subsides, leaving a clear supernatant liquid. Collect the precipitate on counterpoised filters or on a Gooch crucible, wash it well with cold distilled water, and finally with three portions of about 10 cc. each of alcohol. Then close the tip of the funnel with a cork stopper, add sufficient carbon tetrachloride to cover the precipitate, cover the funnel with a watch-glass, and allow it to stand for about half an hour. Then drain off the solvent, and wash the precipitate with further portions of carbon tetrachloride until, after evaporating about 1 cc. of the filtrate, no visible residue remains. Remove the adhering carbon tetrachloride by washing, with several portions of 10 cc. each of alcohol, and, after drying in the air, transfer to an oven and dry to constant weight at about 110° C. The weight of mercuric sulphide obtained, when multiplied by 1.167, indicates its equivalent in $HgCl_2$. Each Gm. of Corrosive Mercuric Chloride, previously dried to constant weight, corresponds to not less than 0.8526 Gm. of Mercuric sulphide.

This assay is explained on page 1479.

Corrosive Mercuric Chloride, previously dried to constant weight, may also be assayed by the electrolytic method, page 1515.

Preserve in well-closed containers.

U. S. P. Preparation—Toxitabellæ Hydrargyri Chloridi Corrosivi.

N. F. Preparations—Elixir Chloridorum; Lotio Flava; Mulla Hydrargyri Chloridi Corrosivi.

History—Although the discovery of corrosive sublimate is credited to Geber of the seventh century, it does not appear to have been used in medicine until the middle of the eighteenth century when it was first employed in syphilis by Baron von Swieten, a pupil of Boerhaave.

Uses—Pharmaceutically, mercuric chloride is used in several preparations to furnish the mercury in the compounds. Medicinally, as an alterative, it is one of the most valuable internal remedies in syphilis and chronic rheumatism, the dose being one-twentieth of a grain (0.003 Gm.). Externally, it is used as a germicide and escharotic. It is very extensively employed in antiseptic surgery. For this purpose it is usually sold in the form of tablets, mixed with sodium chloride, ammonium chloride, or citric acid which render it more readily soluble. These tablets have been so commonly sold and so often mistaken for headache tablets, with fatal results, that the Pharmacopœia and the laws of many States have established rigid regulations for their appearance so as to render them distinctive and readily recognized as poisonous. See *Toxitabellæ Hydrargyri Chloridi Corrosivi* (page 500). Corrosive Mercuric Chloride is a powerful antiseptic, but it must be used with great care on account of its poisonous properties.

Antidotes—(See Part XV, on Antidotes).

HYDRARGYRI CHLORIDUM MITE. U. S. Mild Mercurous Chloride

[**Hydrarg. Chlor. Mit.**—Mercurous Chloride, Calomel, Protochloride of Mercury, Subchloride of Mercury]

Mild Mercurous Chloride, when dried to constant weight over sulphuric acid, contains not less than 99.6 per cent of HgCl (236.06).

Preparation—The former official process may be used to prepare mercurous chloride, as follows:

Take of mercury, 48 oz.; sulphuric acid, 36 oz.; sodium chloride, 18 oz.; distilled water, a sufficient quantity. Boil, by means of a sand bath, 24 oz. of the mercury with the sulphuric acid, until a dry, white mass remains. Rub this, when cold, with the remainder of the mercury, in an earthenware mortar, until they are thoroughly mixed. Then add the sodium chloride, and, having rubbed it with the other ingredients until globules of mercury cease to be visible, sublime the mixture into a large chamber so that the sublimate may fall in powder. Wash the sublimed matter with boiling distilled water until the washings afford no precipitate with ammonia water, and dry it.

In this preparation mercuric sulphate is first made; this is then triturated with a quantity of mercury equal to that used in forming it; mercurous sulphate is produced, and when this is mixed with sodium chloride and sublimed, mercurous chloride is produced as a fine white sublimate, and sodium sulphate remains behind.

$$\underset{\text{sulphuric acid}}{2H_2SO_4} + \underset{\text{mercury}}{Hg} = \underset{\text{mercuric sulphate}}{HgSO_4} + \underset{\text{sulphur dioxide}}{SO_2} + \underset{\text{water}}{2H_2O}$$

$$\underset{\text{mercuric sulphate}}{HgSO_4} + \underset{\text{mercury}}{Hg} = \underset{\text{mercurous sulphate}}{Hg_2SO_4}$$

$$\underset{\text{mercurous sulphate}}{Hg_2SO_4} + \underset{\text{sodium chloride}}{2NaCl} = \underset{\text{mercurous chloride}}{2HgCl} + \underset{\text{sodium sulphate}}{Na_2SO_4}$$

Description and Physical Properties—A heavy, white, impalpable powder, becoming yellowish-white when triturated with strong pressure, and showing only small, isolated crystals when viewed under a lens having a magnifying power of one hundred diameters. It is odorless, and is stable in the air.

Mild Mercurous Chloride is insoluble in water, alcohol, ether, and in cold dilute acids.

When heated to about 383° C., Mild Mercurous Chloride is volatilized without fusion or the evolution of brown vapors.

Tests for Identity—The salt is blackened by contact with calcium hydroxide T.S. with a solution of an alkali hydroxide, or with ammonia T.S.

When heated in a dry glass tube with an equal weight of dried sodium carbonate (free from chloride), Mild Mercurous Chloride yields a sublimate of metallic mercury. When the residue is dissolved in nitric acid and filtered, silver nitrate T.S. produces in the filtrate a white, curdy precipitate, insoluble in nitric acid.

Tests for Purity—When volatilized at about 300° C., Mild Mercurous Chloride leaves not more than 0.1 per cent of residue.

Shake 2 Gm. of the salt with 20 cc. of ether for five minutes, filter, and allow the filtrate to evaporate spontaneously: the residue, dissolved in 10 cc. of distilled water and 2 drops of diluted nitric acid, shows no more *chloride* than corresponds to 0.1 cc. of fiftieth-normal hydrochloric acid (*mercuric chloride*), page 1520.

Heat 1 Gm. of the salt with sodium hydroxide T.S.: no ammonia is evolved (*ammoniated mercury*).

Assay—Dry about 0.7 Gm. of Mild Mercurous Chloride to constant weight over sulphuric acid, weigh accurately, mix well with 10 cc. of distilled water in a glass-stoppered flask, and add 50 cc. of tenth-normal iodine and 5 Gm. of potassium iodide dissolved in 10 cc. of distilled water. Stopper the flask, allow the mixture to stand with occasional agitation until complete solution has taken place, and then titrate the residual iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal iodine corresponds to 0.02361 Gm. of HgCl.

Mild Mercurous Chloride, previously dried to constant weight, may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1471.

Preserve in well-closed containers, protected from light.

U. S. P. Preparation—Pilulæ Hydrargyri Chloridi Mitis Compositæ.

N. F. Preparations—Lotio Nigra; Pulvis Hydrargyri Chloridi Mitis et Jalapæ; Tabellæ Santonini Compositæ; Unguentum Hydrargyri Chloridi Mitis.

History—Calomel is stated to have been first introduced into medical practice by Sir Theodore Turquet de Mayerne, favorite physician of Henry IV, of England. He was a noted character of his time and was one of the compilers of the first London Pharmacopœia of 1618. It was called *Aquila Alba* or *Draco Mitigatus* by early chemical and medical writers. The name calomel is of doubtful origin. It was also called *dulcified mercury*.

Uses—Calomel is a valuable cholagogue cathartic, about two and one-half grains (0.15 Gm.) being given, usually divided into ten or more doses. It is also used as a diuretic and as an intestinal antiseptic, and as an alterative in syphilis and other chronic disorders. It is employed locally for its disinfectant properties, either as a dusting powder or in a 30 per cent ointment which is now official in the N. F. (see page 508).

HYDRARGYRI IODIDUM FLAVUM. U.S. Yellow Mercurous Iodide

[**Hydrarg. Iod. Flav.**—Mercurous Iodide; Protoiodide of Mercury, Yellow Iodide of Mercury]

Yellow Mercurous Iodide, when dried to constant weight over sulphuric acid, contains not less than 99 per cent of HgI (327.52).

Preparation—The process for its manufacture official in the U. S. P. VIII is as follows:

Mix 20 cc. [5 fl. dr.] each of nitric acid and distilled water, and, when the liquid is cold, pour it upon 50 Gm. [1 oz. av. 293 gr.] of mercury contained in a glass beaker. Set the mixture aside in a dark place, and keep it at a temperature between 25° and 30° C. with occasional agitation, until the reaction ceases and a little mercury still remains undissolved. Separate the crystals of mercurous nitrate, which will have formed, from the mother liquor, allow them to drain in a glass funnel, and dry them on bibulous paper, in a dark

place. When the salt is dry, dissolve 40 Gm. [584 gr.] of it in 650 cc. [20½ fl. oz.] of distilled water to which 6 cc. [92 min.] of nitric acid have previously been added. Having prepared a solution of 16 Gm. [233 gr.] of potassium iodide in 32 cc. [1 fl. oz.] of distilled water, slowly pour the solution of potassium iodide into the solution of mercurous nitrate, with constant stirring, which should be continued for fifteen minutes; allow the precipitate to subside, decant the supernatant liquid, and wash the precipitate by decantation with ten successive portions of 500 cc. [1 pint] each of distilled water. Finally, transfer the precipitate to a filter, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 40° C. and keep it in dark amber-colored vials, with the least possible exposure to light.

Instead of weighing off 40 Gm. [584 gr.] of the mercurous nitrate as above directed, the whole of the crystallized salt may be taken and the amount of potassium iodide, etc., adjusted to the proportions given above.

Description and Physical Properties—A bright yellow, amorphous powder, without odor or taste. By exposure to light it becomes greenish in proportion as it undergoes decomposition into metallic mercury and mercuric iodide.

Yellow Mercurous Iodide is practically insoluble in water, and is insoluble in alcohol and in ether.

Tests for Identity—When slowly and moderately heated, Yellow Mercurous Iodide assumes at first an orange and then a red color, becoming yellow again on cooling. When quickly and strongly heated, it is at first partially decomposed into mercury and mercuric iodide, and finally is volatilized.

When heated in a dry glass tube with an equal weight of dried sodium carbonate, Yellow Mercurous Iodide yields a sublimate of metallic mercury.

When Yellow Mercurous Iodide is heated with sulphuric acid and a little manganese dioxide, the vapor of iodine is evolved.

Tests for Purity—When volatilized at about 300° C., Yellow Mercurous Iodide leaves not more than 0.2 per cent of residue.

Place 0.5 Gm. of Yellow Mercurous Iodide in a 10 cc. glass-stoppered cylinder, add 10 cc. of alcohol, shake by inverting the cylinder ten times, allow to stand protected from light for two minutes and shake again by inverting the cylinder ten times. Filter at once, refiltering if necessary until the filtrate is clear, and to 5 cc. of the filtrate add an equal volume of hydrogen sulphide T.S. The color produced is not darker than that produced by 5 cc. of hydrogen sulphide T.S. in a mixture of 1 cc. of mercuric chloride solution (made by dissolving 0.5 Gm. of mercuric chloride in 1000 cc. of distilled water) and 4 cc. of alcohol (*mercuric iodide*).

Assay—Dry about 1 Gm. of Yellow Mercurous Iodide to constant weight over sulphuric acid, weigh accurately, transfer to a glass-stoppered flask, add 50 cc. of tenth-normal iodine and 5 Gm. of potassium iodide dissolved in 10 cc. of distilled water. Stopper the flask, and allow the mixture to stand with occasional agitation until complete solution has taken place, and then titrate the residual iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal iodine corresponds to 0.03275 Gm. of HgI.

Yellow Mercurous Iodide, previously dried to constant weight, may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1472.

Preserve in well-closed containers, protected from light.

Uses—Yellow mercurous iodide is used as an alterative. It is better adapted for internal administration than the red iodide, because it is milder. The dose is from one-sixth to one grain (0.01 to 0.065 Gm.).

Antidotes—(See Part XV, on Antidotes).

HYDRARGYRI IODIDUM RUBRUM. U.S. Red Mercuric Iodide

[**Hydrarg. Iod. Rub.**—Biniodide of Mercury, Mercuric Iodide, Red Iodide of Mercury]

Red Mercuric Iodide, when dried to constant weight over sulphuric acid, contains not less than 99 per cent of HgI_2 (454.44).

Preparation—The process for its manufacture official in the U.S.P. VIII is as follows:

	Metric	Alternative
Corrosive Mercuric Chloride	**40 Gm.**	1 oz. av. 148 gr.
Potassium Iodide	**50 Gm.**	1 oz. av. 293 gr.

Distilled Water, a sufficient quantity.

Dissolve 40 Gm. [1 oz. av. 148 gr.] of corrosive mercuric chloride and 50 Gm. [1 oz. av. 293 gr.] of potassium iodide, each, in 800 cc. [25½ fl. oz.] of distilled water, and filter the solutions separately. Pour both solutions, simultaneously and in a thin stream, with constant and very active stirring, into 2000 cc. [4 pints] of distilled water. When the precipitate has subsided, decant the supernatant liquid, collect the precipitate on a filter, and wash it with cold distilled water until the washings give not more than a slight opalescence with silver nitrate test solution. Finally, dry it in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C., and keep it in well-stoppered bottles, protected from light.

In this process mercuric iodide and potassium chloride are formed by double decomposition.

$$\underset{\text{mercuric chloride}}{HgCl_2} + 2KI = \underset{\text{mercuric iodide}}{HgI_2} + \underset{\text{potassium chloride}}{2KCl}$$

As mercuric iodide is soluble in solutions both of mercuric chloride or of potassium iodide, it is not profitable to use an excess of either. It may be obtained in handsome crystals by dissolving it in hot hydrochloric acid to saturation and allowing the solution to cool slowly.

Description and Physical Properties—A scarlet-red, amorphous powder without odor. It is stable in the air.

Caution—Red Mercuric Iodide is extremely poisonous.

Red Mercuric Iodide is practically insoluble in water. One Gm. is soluble in 115 cc. of alcohol, 910 cc. of chloroform, and in 120 cc. of ether, at 25° C. One Gm. is soluble in 20 cc. of boiling alcohol. It is dissolved by solutions of the soluble iodides, mercuric chloride, sodium thiosulphate, and by hot solutions of the alkali chlorides.

When heated to about 150° C., Red Mercuric Iodide becomes yellow, but again assumes a red color on cooling. At about 250° C. it fuses to a dark yellow liquid, which, on cooling, forms a yellow, crystalline mass. At about 350° C. it is volatilized.

Tests for Identity—Boil about 0.1 Gm. of the salt with 2 cc. of sodium hydroxide T.S., filter, and strongly acidify the filtrate with nitric acid: the liquid becomes yellow from the liberation of iodine, which produces a blue color upon the addition of a few drops of starch T.S.

Heat the salt with potassium hydroxide T.S. and add a little lactose: metallic mercury is precipitated.

Tests for Purity—When volatilized at about 300° C., Red Mercuric Iodide leaves not more than 0.2 per cent of residue.

Agitate thoroughly about 0.5 Gm. of Red Mercuric Iodide with 10 cc. of distilled water, and filter: the filtrate does not become more than slightly colored upon the addition of hydrogen sulphide T.S. (*soluble mercury salts*).

Not more than 0.004 Gm. of insoluble residue remains on dissolving 2 Gm. of Red Mercuric Iodide in 100 cc. of distilled water containing 2 Gm. of potassium iodide.

Assay—Dry Red Mercuric Iodide over sulphuric acid to constant weight and assay by the electrolytic method, page 1515.

Preserve in well-closed containers, protected from light.

U. S. P. Preparation—Liquor Arseni et Hydrargyri Iodidi.

Uses—This iodide is used internally in the treatment of syphilis, in doses of one-twentieth of a grain (0.003 Gm.); it is frequently combined with potassium iodide. It is also offered in one per cent suspension in neutral oil, mixed with benzocaine. Externally, it is often used in the form of an ointment, of the strength of sixteen grains in an ounce of simple ointment.

Antidotes—(See Part XV, on Antidotes).

HYDRARGYRI OXIDUM FLAVUM. U. S. Yellow Mercuric Oxide [Hydrarg. Oxid. Flav.]

Yellow Mercuric Oxide, when dried to constant weight at 150° C., contains not less than 99.5 per cent of HgO (216.60).

Preparation—The process for its manufacture official in the U. S. P. VIII is as follows:

Dissolve 100 Gm. [3 oz. av. 148 gr.] of corrosive mercuric chloride in 1000 cc. [2 pints] of warm distilled water, and filter the solution. Dissolve 40 Gm. [1 oz. av. 147 gr.] of sodium hydroxide (which should contain at least 90 per cent of pure, anhydrous sodium hydroxide) in 1000 cc. [2 pints] of cold distilled water, and into this solution pour gradually, and with constant stirring, the solution of corrosive mercuric chloride. Allow the mixture to stand for an hour at a temperature of about 30° C., stirring frequently. Then decant the supernatant, clear liquid from the precipitate, and wash the latter repeatedly by the addition and decantation of portions of distilled water, using 1000 cc. [2 pints] of water each time. Collect the precipitate on a strainer, and continue the washing with warm distilled water, until a small portion of the washings, when poured on a little mercuric chloride test solution, no longer produces a yellowish turbidity at the line of contact of the two liquids. Then allow the precipitate to drain, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. and keep it in well-stoppered bottles, protected from light.

$$\underset{\text{mercuric chloride}}{HgCl_2} + \underset{\text{sodium hydroxide}}{2NaOH} = \underset{\text{mercuric oxide}}{HgO} + \underset{\text{sodium chloride}}{2NaCl} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—A light orange-yellow, odorless, amorphous, heavy, impalpable powder. It is stable in the air, but turns darker on exposure to light.

Yellow Mercuric Oxide is practically insoluble in water, and insoluble in alcohol. It is readily dissolved by diluted hydrochloric or nitric acid, forming colorless solutions.

Test for Identity—When moderately heated, Yellow Mercuric Oxide assumes a red color. At about 600° C. it is completely decomposed into oxygen and metallic mercury, and is volatilized.

Tests for Purity—When volatilized at about 300° C., Yellow Mercuric Oxide leaves not more than 0.2 per cent of residue.

When moistened with hot, distilled water, Yellow Mercuric Oxide is not alkaline to litmus paper.

A solution of 0.5 Gm. of Yellow Mercuric Oxide in 25 cc. of either diluted hydrochloric or diluted nitric acid is not more than slightly turbid.

Heat 0.5 Gm. of Yellow Mercuric Oxide for two hours in a test tube, on a water bath, with a solution of 1 Gm. of oxalic acid in 10 cc. of distilled water and 1 cc. of ammonia T.S., replacing from time to time the water lost by evaporation: it is converted into white or yellowish-white mercuric oxalate (*distinction from red mercuric oxide*).

Assay—Dry about 0.5 Gm. of Yellow Mercuric Oxide to constant weight at 150° C., weigh accurately, and dissolve it in a mixture of 10 cc. of distilled water and 5 cc. of nitric acid, and further dilute the solution with 150 cc. of distilled water. Then add 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01083 Gm. of HgO.

Yellow Mercuric Oxide, previously dried to constant weight, may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1461.

Preserve in well-closed containers, protected from light.

U. S. P. Preparations—Oleatum Hydrargyri; Unguentum Hydrargyri Oxidi Flavi.

Uses—Yellow mercuric oxide is used in making the oleate of mercury (see page 350) and in the official ointment (see page 505); it is employed only externally for its antiseptic powers. The official ointment is now only 1 per cent and is largely used for inflammation of the eyelids. The U. S. P. IX ointment was 10 per cent and was used for vermin in the hair.

HYDRARGYRI SALICYLAS. U.S. Mercuric Salicylate

[Hydrarg. Salicyl.—Mercuric Subsalicylate]

Mercuric Salicylate is a compound of mercury and salicylic acid containing not less than 54 per cent and not more than 59.5 per cent of Hg.

Preparation—The formula for this salt is indefinite, but has been given as $Hg.C_6H_4O.CO_2$. The mercury replaces both carboxyl and hydoxyl hydrogen

in the salicylic acid. It is sometimes called *salicylated mercury*. It may be prepared as follows:

Dissolve 27 parts of corrosive mercuric chloride in 600 parts of distilled water, and filter. Dissolve 10.8 parts of sodium hydroxide in 600 parts of cold distilled water, and pour the corrosive sublimate solution into this with constant stirring. Allow it to stand for an hour, with frequent stirring, at a temperature of about 30° C. (86° F.) and then wash the precipitated mercuric oxide. Now digest this freshly precipitated oxide with a little water and 15 parts of salicylic acid at a boiling temperature until the mixture becomes white; collect the mercuric salicylate on a filter, wash until the filtrate is no longer acid and dry at a temperature between 30° and 40° C. (86° and 104° F.) and finally at 100° C. (212° F.).

Description and Physical Properties—An odorless, white, slightly yellowish or slightly pinkish powder.

Mercuric Salicylate is practically insoluble in water and in alcohol. It is dissolved by solutions of the fixed alkalies or their carbonates and by warm solutions of the alkali halides, with the formation of double salts.

Tests for Identity—Heat 1 Gm. of Mercuric Salicylate with 10 cc. of hydrochloric acid: a solution is obtained from which salicylic acid separates on cooling. A piece of copper foil added to a portion of the filtered solution, nearly neutralized with ammonia T.S., immediately becomes coated with metallic mercury.

To a mixture of 1 Gm. of Mercuric Salicylate with 10 cc. of distilled water add a few drops of ferric chloride T.S.: a violet color is produced.

Tests for Purity—When volatilized at about 300° C., Mercuric Salicylate leaves not more than 0.2 per cent of residue.

Mercuric Salicylate does not redden moistened blue litmus paper (*free salicylic acid*).

No dark color results at once on shaking about 0.1 Gm. of Mercuric Salicylate with 5 cc. of hydrogen sulphide T.S. (*foreign mercury compounds*). About 0.2 Gm. of Mercuric Salicylate dissolves completely in 4 cc. of normal sodium hydroxide.

Assay—Digest about 0.5 Gm. of Mercuric Salicylate, accurately weighed, in a mixture of 15 cc. of sulphuric acid and 10 cc. of nitric acid contained in a long neck flask in which a small funnel is inserted. Heat it upon a sand bath until the mixture is nearly colorless, then add another 10 cc. of nitric acid, and heat until the mixture is decolorized. Cool the solution, dilute it with 150 cc. of distilled water, add 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate until a permanent yellowish-red color is produced. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01003 Gm. of Hg.

Mercuric Salicylate may also be assayed by the electrolytic method, page 1515.

This assay is explained on page 1461.

Preserve in well-closed containers, protected from light.

Uses—It is used medicinally as an intra-muscular injection in syphilis; dose, 1 grain (0.06 Gm.) twice a week, suspended (1 in 10) in neutral oil. Wollheim recommends the following formula for its suspension for hypodermic injection: 2 Gm. of quinine and urea hydrochloride, 2 cc. of distilled water, 12 Gm. of anhydrous wool fat, 10 Gm. of mercuric salicylate and sufficient olive oil to make 100 cc. (see also *Ampuls of Mercuric Salicylate*). The mixture should be sterilized before use. Some mixtures contain cacao butter.

HYDRARGYRI OXIDUM RUBRUM. N. F. Red Mercuric Oxide

(U. S. P. IX)

[Hydrarg. Oxid. Rub.—Red Precipitate]

Red Mercuric Oxide contains, when dried to constant weight at 150° C., not less than 99.5 per cent of HgO (216.60).

Preparation—This oxide may be prepared by dissolving 36 oz. av. of mercury in 24 oz. av. of nitric acid and water to make 2 pints, with the aid of gentle heat, the acid and the water being previously mixed. The solution is then evaporated to dryness when a residue of mercuric nitrate is obtained. The dry mass is then rubbed into a powder and heated in a

very shallow vessel until red vapors are no longer evolved. By this time the heat has decomposed the salt leaving a residue of mercuric oxide. The equation is as follows:

$$\underset{\text{mercuric nitrate}}{2Hg(NO_3)_2} = \underset{\text{mercuric oxide}}{2HgO} + \underset{\text{nitrogen dioxide}}{4NO_2} + \underset{\text{oxygen}}{O_2}$$

Description and Physical Properties—Red Mercuric Oxide occurs as heavy, orange-red, crystalline scales, or as a crystalline powder, acquiring a yellow color when finely divided; odorless and having a somewhat metallic taste, permanent in the air.

Red Mercuric Oxide is almost insoluble in water; insoluble in alcohol; readily dissolved by diluted nitric acid, or by hydrochloric acid.

Tests for Identity—When heated to about 400° C., Red Mercuric Oxide becomes dark violet or almost black, but assumes its original color on cooling. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized without leaving more than 0.2 per cent of residue.

A solution of 0.5 Gm. of Red Mercuric Oxide in 25 cc. of either hydrochloric or nitric acid is not more than slightly turbid.

Tests for Purity—Heat 0.5 Gm. of Red Mercuric Oxide for two hours, in a test tube on a water bath, with a solution of 1 Gm. of oxalic acid in 10 cc. of distilled water and 1 cc. of ammonia water, replacing, from time to time, the water lost by evaporation; it will not change color within two hours (distinction from yellow mercuric oxide).

Mix 1 Gm. of Red Mercuric Oxide with 5 cc. of distilled water, add 2 cc. of sulphuric acid, cool the mixture and carefully pour upon it 2 cc. of ferrous sulphate T.S.; no brown zone develops at the line of contact (*nitrate*).

Assay—Dissolve about 0.5 Gm. of Red Mercuric Oxide, previously dried to constant weight at 150° C. and accurately weighed, in 10 cc. of distilled water and 5 cc. of nitric acid, and further dilute the solution with 150 cc. of distilled water. Then add 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate to the production of a permanent yellowish-red color.

Each cc. of tenth-normal potassium thiocyanate used corresponds to 0.01083 Gm. of HgO. Each Gm. of Red Mercuric Oxide, previously dried to constant weight, corresponds to not less than 91.9 cc. of tenth-normal potassium thiocyanate.

This assay is explained on page 1461.

Red Mercuric Oxide, previously dried to constant weight, may also be assayed by the electrolytic method (see U. S. P. X).

Preserve it in well-closed containers, protected from light.

N. F. Preparation—Unguentum Hydrargyri Oxidi Rubri.

Uses—Red mercuric oxide has the same chemical composition as the yellow oxide. It is used in the form of ointment for inflamed eyelids, in skin diseases, and for destroying body vermin. A 10 per cent ointment is official in the N. F. (see page 509). There is difficulty in rubbing down the crystalline powder to a smooth ointment. In fact, when reduced to a proper degree of fineness, it corresponds to the yellow oxide, and the Pharmacopœia has adopted only the yellow oxide for the preparation of its 1 per cent ointment. The yellow oxide is largely replacing the red oxide.

Unofficial Salts of Mercury

Hydrargyri Acetas, $Hg(C_2H_3O_2)_2$ Mercuric Acetate	A white, crystalline powder. It is soluble in water and is poisonous. It is used in medicine
Hydrargyri Benzoas, $Hg(C_6H_5COO)_2.H_2O$ Mercuric Benzoate	A white, crystalline salt; slightly soluble in water. Its chief use is in medicine
Hydrargyri Bromidum, $HgBr_2$ Mercuric Bromide	A poisonous, white, crystalline salt; slightly soluble in water. It is used in medicine
Hydrargyri Carbonas, Hg_2CO_3 Mercurous Carbonate	An unimportant black, or yellow powder; insoluble in water. It is readily decomposed by heat and by hot water
Hydrargyri Chloras, $Hg(ClO_3)_2$ Mercuric Chlorate	White, crystalline needles, easily decomposed by heat; slightly soluble in water. It has been used in medicine but is of little importance
Hydrargyri Chromas, $HgCrO_4$ Mercuric Chromate	A dark red crystalline powder; slightly soluble in water. It is decomposed by heat and by acids
Hydrargyri Cyanidum, $Hg(CN)_2$ Mercuric Cyanide	Poisonous, colorless, transparent crystals which darken on exposure to light. It is soluble in water and is used in medicine, in photography, and in the manufacture of cyanogen gas
Hydrargyri Oxycyanidum $Hg(CN)_2.HgO$ Mercuric Oxycyanide	White, crystalline needles, slightly soluble in water. Used as a germicide; more powerful than mercuric chloride and does not corrode steel instruments
Hydrargyri Subsulphas Flavus, $Hg(HgO)_2SO_4$ Yellow Mercuric Subsulphate	A yellow powder commonly called *turpeth mineral*. It is practically insoluble in water. The salt reddens when heated, turning yellow again when cooled. It is decomposed at higher temperatures
Hydrargyri Sulphidum Nigrum, HgS Black Mercuric Sulphide Ethiops Mineral	A black powder; insoluble in water but soluble in sodium sulphide solution. It is used as a pigment

Unofficial Salts of Mercury—*Continued*

Hydrargyri Sulphidum Rubrum, HgS Red Mercuric Sulphide Vermilion	A fine, bright scarlet powder. It is insoluble in water and is used in medicine and as a pigment in paints and in sealing wax
Hydrargyri Nitras, $HgNO_3 + H_2O$ Mercurous Nitrate	White or colorless crystals, readily soluble in water but decomposed by an excess of warm or hot water, with the formation of the basic nitrate. It is used as a reagent and in the manufacture of mercurous salts by precipitation
Hydrargyri Sulphas, $HgSO_4$ Mercuric Sulphate	A white, crystalline powder. It is decomposed at red heat and is decomposed by water, yielding basic mercuric sulphate as the result of its hydrolysis. It is used in medicine and in the manufacture of calomel and corrosive sublimate
Potassii Hydrargyri Iodidum, K_2HgI_4 Potassium Mercuric Iodide	Yellow crystals that are deliquescent and very soluble in water. It is formed when mercuric iodide is dissolved in an excess of potassium iodide solution. Potassium mercuric iodide is the active ingredient in Mayer's reagent and in Nessler's solution. It is also used in medicine and is more fully described in the New and Non-official Remedies of 1925

See also organic mercury compounds, Chapter LXI, page 878

CHAPTER LV

ANTIMONY, ARSENIC, AND BISMUTH

Sb; 120.2. As; 74.96. Bi; 209.0

These three metals have the Latin names *Antimonium*, *Arsenium*, and *Bismuthum*. They form a group which presents several analogies. Arsenic is regarded by a number of chemists as not metallic, and on account of some of its chemical relations is classed by them with the non-metallic elements, but in some of its physical properties, notably its luster, specific gravity, etc., it closely resembles the metals, and it is therefore considered in the group with antimony and bismuth.

Antimony (Stibium), Sb; 120.2

The exact derivation of the name *antimony* is unknown. There is a legend that certain monks were poisoned by it by Basil Valentine, its alleged discoverer, and that the name is derived from anti, "against", and moine, "a monk", so that the name antimony means "monk's bane", or something of that sort.

Several centuries ago metallic antimony was employed in medicine in pill form. The pills were called *Pilulæ Perpetuæ* or everlasting pills, because they were recovered from the stool of the patient, cleansed by washing and used over and over again.

The metal is found in nature in a free state, but more frequently as a sulphide, oxide, or oxysulphide. The native sulphide (called *antimonite*) is the chief source of the metal, and roasting with iron and sodium sulphide is the process generally resorted to for obtaining it. It is a brittle, brilliant metal, of a lamellated texture, of a silver-white color when pure, but bluish-white as it occurs in commerce. When rubbed between the fingers, it imparts a distinctive odor. Its specific gravity is 6.7, and its fusing point 432° C. (809.6° F.), or about a red heat. It forms three combinations with oxygen—*antimony trioxide* (antimonous oxide), Sb_2O_3; *antimony tetroxide*, Sb_2O_4 (by some considered to be an antimonate of the tetroxide of antimony, Sb_4O_8); and *antimony pentoxide* (antimonic oxide), Sb_2O_5. The first of these unites with water to form *ortho-* or meta-antimonous acid, the salts of which are called *meta-antimonites*; the third unites with water to from *ortho-, meta-, or pyro-antimonic acid,* the salts of which are called *ortho-, meta-, or pyro-antimonates.*

Tests for Salts of Antimony

1. If hydrogen sulphide is added to an acidified solution of salt of antimony, an orange-red precipitate of sulphide will be produced. This is soluble in ammonium sulphide, but is again precipitated upon the addition of an acid.

2. If hydrochloric acid is added to the sulphide, so as to form a strong solution of antimonous chloride, and this mixed with water, a white precipitate of oxychloride will be produced.

3. Zinc and iron precipitate antimony as a black powder from its solutions; copper precipitates it as a metallic film; this may be dissolved by potassium permanganate, and this solution will yield antimony sulphide with hydrogen sulphide.

ANTIMONII ET POTASSII TARTRAS. U. S. Antimony and Potassium Tartrate

[**Antim. et Pot. Tart.**—Antimonyl Potassium Tartrate, Tartrated Antimony, Tartar Emetic]

Antimony and Potassium Tartrate contains not less than 98.5 per cent of $K(SbO)C_4H_4O_6.\frac{1}{2}H_2O$ (332.36).

Preparation—This, the most important antimonial compound, may be made by a former official process, as follows:

Take of antimony oxide, in very fine powder, 2 oz.; potassium bitartrate, in very fine powder, 2½ oz.; distilled water, 18 fl. oz. To the water, heated to the boiling point in a glass vessel, add the powders, previously mixed, and boil for an hour; then filter the liquid while hot, and set it aside that crystals may form. Lastly, dry the crystals, and keep them in a well-stoppered bottle. By further evaporation, the mother water may be made to yield more crystals, which should be purified by a second crystallization.

Like potassium and sodium tartrate, this is a double salt. Two replaceable hydrogen atoms of tartaric acid ($H_2C_4H_4O_6$) are substituted by one of antimonyl (SbO) and one of potassium (K). The group (SbO) is hypothetical.

$$\underset{\text{acid potassium tartrate}}{2KHC_4H_4O_6} + \underset{\text{antimonous oxide}}{Sb_2O_3} = \underset{\text{antimony and potassium tartrate}}{2K(SbO)C_4H_4O_6} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—Colorless, odorless, transparent crystals of the rhombic system, or a white granular powder. The crystals effloresce upon exposure to air.

One Gm. of Antimony and Potassium Tartrate is soluble in 12 cc. of water and in 15 cc. of glycerin, at 25° C. One Gm. is soluble in 3 cc. of boiling water. It is insoluble in alcohol.

Tests for Identity—An aqueous solution of Antimony and Potassium Tartrate (1 in 20) is slightly acid to litmus paper.

When heated to redness, it chars, emits an odor resembling that of burning sugar, and leaves a blackened residue. This residue has an alkaline reaction, and when a small fragment of it is held in a non-luminous flame, a violet tint is produced.

In an aqueous solution of Antimony and Potassium Tartrate (1 in 20), acidulated with hydrochloric acid, hydrogen sulphide T.S. produces an orange-red precipitate, which is soluble in ammonium sulphide T.S. or potassium hydroxide T.S.

Tests for Purity—A 10 cc. portion of an aqueous solution of the salt (1 in 100) acidulated with acetic acid does not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide T.S. (*iron*).

Dissolve 0.1 Gm. of Antimony and Potassium Tartrate in 5 cc. of concentrated hydrochloric acid: the solution meets the requirements of Bettendorf's Test for *arsenic*, page 1512.

Assay—Dissolve about 0.5 Gm. of Antimony and Potassium Tartrate, accurately weighed, in 30 cc. of distilled water, add 25 cc. of a cold, saturated solution of sodium bicarbonate and a few drops of starch T.S., and immediately titrate with tenth-normal iodine to the production of a permanent blue color. Each cc. of tenth-normal iodine corresponds to 0.01662 Gm. of $K(SbO)C_4H_4O_6.\frac{1}{2}H_2O$.

This assay is explained on page 1470.

Preserve in well-closed containers.

U. S. P. Preparations—Mistura Glycyrrhizæ Composita; Syrupus Scillæ Compositus.
N. F. Preparation—Tinctura Antimonii.

History—Adrian Mynsicht, the celebrated German physician of the early seventeenth century, who invented Elixir of Vitriol, is also credited with having first discovered and used tartar emetic. Glauber in 1648 described in detail the process of preparing *Mynsicht's Emetic Tartar* as it was then called.

Uses—Tartar emetic is now rarely used as an emetic. It is employed chiefly as a diaphoretic and expectorant. It also is of value in certain chronic infections, especially African sleeping sickness.

Dose—One-twentieth grain (0.003 Gm.).

Antidotes—(See Part XV, on Antidotes).

ANTIMONII OXIDUM. N. F. Antimony Oxide
[Antim. Oxid.]

Antimony Oxide contains not less than 97 per cent of antimonous oxide ($Sb_2O_3 = 288.4$).

Preparation—It may be prepared by pouring a solution of antimonous chloride into a large bulk of water to precipitate the oxychloride and then decomposing this by the addition of sodium carbonate.

Description and Physical Properties—Antimony Oxide is a white or grayish-white powder, odorless and tasteless.

It is insoluble in water, alcohol or nitric acid; readily dissolved by hydrochloric acid without effervescence, and also by a warm aqueous solution of tartaric acid or by a boiling aqueous solution of potassium bitartrate.

When heated Antimony Oxide turns yellow, but it again becomes white on cooling. At a dull red heat it fuses to a yellowish liquid and at a higher temperature it volatilizes.

Tests for Identity—Dissolve Antimony Oxide in a slight excess of hydrochloric acid and dilute the solution with a large volume of distilled water; a white precipitate is produced which is changed to orange by hydrogen sulphide.

Tests for Purity—A solution of 0.1 Gm. of the Oxide in 3 cc. of hydrochloric acid and 5 cc. of distilled water is not rendered turbid at once by a few drops of barium chloride T.S. (*sulphate*).

A solution of 0.1 Gm. of the Oxide in 10 cc. of distilled water and 1 Gm. of tartaric acid does not become more than slightly opalescent on the addition of 0.2 cc. of nitric acid and 0.2 cc. of silver nitrate T.S. (*chloride*).

Dissolve 0.5 Gm. of the Oxide in 10 cc. of hydrochloric acid, dilute the solution with distilled water until it begins to become permanently turbid and then precipitate with hydrogen sulphide. This precipitate when thoroughly washed with distilled water dissolves in ammonium sulphide T.S. or sodium sulphide T.S., without leaving a black insoluble residue (*copper* or *lead*).

A solution of 0.1 Gm. of Antimony Oxide in 5 cc. of hydrochloric acid does not respond to Bettendorf's test for arsenic (see page 1512).

Assay—Dissolve about 0.2 Gm. of Antimony Oxide, accurately weighed, by warming it in a solution of 1 Gm. of tartaric acid in 10 cc. of distilled water (adding a few drops of hydrochloric acid to aid the solution). Nearly neutralize the solution with sodium carbonate, then add 40 cc. of a cold saturated solution of sodium bicarbonate and titrate at once with tenth-normal iodine, using starch T.S. as indicator.

Each cc. of tenth-normal iodine corresponds to 0.00721 Gm. of Sb_2O_3. One Gm. of Antimony Oxide corresponds to not less than 134.5 cc. of tenth-normal iodine.

This assay is explained on page 1470.

N. F. Preparation—Pulvis Antimonialis.

Uses—It is rarely given uncombined. It is an ingredient in antimonial powder (see page 481). The dose is one grain (0.06 Gm.).

Unofficial Salts of Antimony

Antimonii Bromidum, $SbBr_3$ Antimony Bromide	A yellowish-white, crystalline salt; deliquescent; decomposed by water, yielding a basic bromide of antimony. It is used as a reagent
Antimonii Chloridum, $SbCl_3$ Antimony Trichloride	Commonly called *butter of antimony*. A colorless, transparent, crystalline mass; soluble in water but decomposed by a large amount of water, yielding the insoluble basic chloride. It is used in the manufacture of antimony salts, in bronzing iron and steel, as a mordant, and as a caustic in veterinary practice
Antimonii Fluoridum, SbF_3 Antimony Fluoride	Heavy colorless, deliquescent crystals; soluble in water containing potassium fluoride. It is used in ceramics and as a mordant for cotton goods
Antimonii Iodidum, SbI_3 Antimony Iodide	A brownish-red, crystalline mass. It is decomposed by water, yielding a basic compound
Antimonii Pentasulphidum, Sb_2S_5 Antimony Pentasulphide	Called *golden sulphide of antimony*. An orange-red, insoluble powder that dissolves in alkali sulphide solutions. It is decomposed by heat, yielding antimony trisulphide and sulphur. It is used in the vulcanizing of rubber
Antimonii Sulphas, $Sb_2(SO_4)_3$ Antimony Sulphate	An explosive white powder; decomposed by water. It is used in explosives and in pyrotechnics
Antimonii Sulphidum, Sb_2S_3 Antimony Trisulphide (U. S. P. 1890)	A grayish-black, crystalline powder when from the natural source. This is called *black antimony*. When made by precipitation it is an orange-red, crystalline powder. Both forms are insoluble in water and both are used as pigments. The black antimony is also employed in medicine and in condition powders for horses and cattle
Antimonii Sulphidum Purificatum, Sb_2S_3 Purified Antimony Sulphide (U. S. P. 1890)	A heavy, grayish-black powder; insoluble in water but dissolved in hydrochloric acid with the evolution of hydrogen sulphide. It is purified by treatment with ammonia water
Antimonium Sulphuratum, Sb_2S_3 and Sb_2O_3 (N. F. IV) Sulphurated Antimony, Antimony Oxysulphide Kermes Mineral	A brown-red powder, insoluble in water, becoming lighter on exposure to air. It is odorless and tasteless and is insoluble in water and in alcohol. It is used as an alterative and diaphoretic in doses of from one to five grains (0.06 to 0.3 Gm.)

Arsenic, As; 74.96

The name *arsenic* is probably from the Greek word "arsen" signifying male. The yellow sulphide of arsenic was known to Dioscorides who called it "arsenikon", probably on account of its powerful properties. It is found in many minerals, generally as sulphides (*realgar*, As_2S_2, and *orpiment*, As_2S_3,) or as *arsenopyrite*, FeAsS. It may be easily obtained from arsenous oxide by heating it with charcoal. Arsenic is a brilliant crystalline element, of a steel-gray color when freshly sublimed; upon exposure to the air its surface becomes blackish and dull. Its specific gravity is 5.63 to 5.73. It forms two combinations with oxygen, arsenous and arsenic oxides, As_2O_3 and As_2O_5, respectively, the corresponding acids to the first being *arsenous acid* (H_3AsO_3, known only in solution) and *metarsenous acid* ($HAsO_2$, known only in salts) and to the second *ortho-arsenic acid* (H_3AsO_4), *pyro-arsenic acid* ($H_4As_2O_7$), and *meta-arsenic acid* ($HAsO_3$), and three with sulphur,—namely, the disulphide, or *realgar*, As_2S_2; the trisulphide, or *orpiment*, As_2S_3, corresponding in composition to arsenous oxide; and the pentasulphide, As_2S_5, corresponding to arsenic oxide.

Tests for Arsenic and its Salts

Arsenates—Soluble arsenates yield with silver nitrate T.S. a dark red precipitate which is soluble in diluted nitric acid. When hydrogen sulphide is passed into a solution of an arsenate containing hydrochloric acid, a yellow precipitate is slowly formed. This precipitate is soluble in ammonium sulphide T.S. Soluble arsenates yield a white precipitate with magnesia mixture T.S.

Arsenous Compounds—Solution of arsenous compounds, to which hydrochloric acid has been added, yield with hydrogen sulphide a yellow precipitate which is insoluble in strong hydrochloric acid but soluble in ammonium carbonate T.S.

ARSENI TRIOXIDUM. U.S. Arsenic Trioxide

[Arsen. Triox.—Arsenous Acid, Arsenous Oxide, White Arsenic]

Arsenic Trioxide, when dried to constant weight at 100° C., contains not less than 99.8 per cent of As_2O_3(197.92).

Note—*Powdered Arsenic Trioxide when administered in solid form, as in powders, tablets, and pills, must consist of particles not greater than* 0.0125 *mm. in diameter.*

Preparation—Arsenic trioxide, or, as it is commonly termed, *arsenic*, is made by roasting arsenical ores in reverberatory furnaces with long, horizontal flues; the arsenic trioxide collects as a solid sublimate, which is afterwards resublimed in cast iron vessels with conical heads. It is also formed by burning metallic arsenic in air. In either case the roasting or the burning effects a direct combination of arsenic with oxygen as expressed by the equation:

$$\underset{\text{arsenic}}{As_2} + \underset{\text{oxygen}}{3O_2} = \underset{\text{arsenic trioxide}}{2As_2O_3}$$

Chemically, it is an oxide, As_2O_3, the acid being formed when the oxide is dissolved in water.

$$\underset{\text{arsenic trioxide}}{2As_2O_3} + \underset{\text{water}}{6H_2O} = \underset{\text{arsenous acid}}{4H_3AsO_3}$$

Description and Physical Properties—A white powder, or irregular masses of two varieties, one amorphous, transparent, and colorless, like glass; the other, crystalline, opaque and white, resembling porcelain. Frequently the same piece has an opaque, white, outer crust enclosing the

glassy variety. Contact with moist air gradually changes the glassy into the white, opaque variety. All varieties are odorless.

Caution—Arsenic Trioxide is extremely poisonous.

Arsenic Trioxide is slowly soluble in water, the amorphous or glassy variety being somewhat more soluble than the crystalline. It is slightly soluble in alcohol and in ether, and freely soluble in glycerin. It is dissolved by hydrochloric acid and by solutions of alkali hydroxides and carbonates.

Tests for Identity—An aqueous solution of Arsenic Trioxide is faintly acid to litmus paper.

When slowly heated in a dry test tube of hard glass, Arsenic Trioxide yields a sublimate of minute crystals. When heated rapidly to about 200° C., the amorphous variety fuses, then sublimes, while the crystalline variety sublimes without fusing.

When Arsenic Trioxide is covered with charcoal in an ignition tube and strongly heated, it is reduced to metallic arsenic which is deposited on the cooler portion of the tube as a mirror, having a metallic luster. This mirror is rapidly soluble in solutions of chlorinated lime or chlorinated soda.

Hydrogen sulphide T.S. colors an aqueous solution of Arsenic Trioxide (1 in 100) yellow. Upon the addition of a few drops of hydrochloric acid to the colored solution, a lemon-yellow precipitate of arsenic trisulphide is produced.

Tests for Purity—Not more than 0.1 per cent of residue remains upon the ignition of 1 Gm. of Arsenic Trioxide.

Dissolve 1 Gm. of Arsenic Trioxide in 10 cc. of ammonia T.S. with the aid of gentle heat: a clear, colorless solution results.

Dissolve about 0.2 Gm. of Arsenic Trioxide in 50 cc. of distilled water with the aid of 2 cc. of hydrochloric acid and completely precipitate by hydrogen sulphide. Allow the precipitate to subside, and pour off the clear liquid: the precipitate dissolves completely upon the addition of an excess of ammonium carbonate T.S. (*antimony, tin, or cadmium*).

Assay—Dissolve about 0.2 Gm. of Arsenic Trioxide, previously dried to constant weight at 100° C. and accurately weighed, in 20 cc. of boiling distilled water, and gradually add sodium hydroxide T.S. until complete solution results. Neutralize this solution with diluted sulphuric acid, using phenolphthalein T.S. as indicator, cool, dissolve in it 2 Gm. of sodium bicarbonate, and titrate the mixture with tenth-normal iodine, using starch T.S. as indicator. Each cc. of tenth-normal iodine corresponds to 0.004948 Gm. of As_2O_3.

This assay is explained on page 1470.

U. S. P. Preparations—Liquor Acidi Arsenosi; Liquor Potassii Arsenitis.

N. F. Preparations—Liquor Auri et Arseni Bromidi; Pilulæ Ferri, Quininæ, Strychninæ et Arseni Fortiores; Pilulæ Ferri, Quininæ, Strychninæ et Arseni Mites.

Uses—Arsenic trioxide is used as an alterative and tonic in doses of one-thirtieth of a grain (0.002 Gm.); externally, it is employed as an escharotic, and, mixed with various substances in the form of a paste, is often applied to cancers and ulcers.

Antidotes—An antidote to arsenical poisoning is official (see page 717), and the treatment of arsenic poisoning is discussed in Part XV, under Antidotes.

NOTE—*The fine degree of subdivision of the powdered form of this arsenic trioxide renders it more soluble and therefore more effective than the powder previously official. This should be borne in mind in adjusting the dosage.*

LIQUOR ACIDI ARSENOSI. U. S. Solution of Arsenous Acid

[**Liq. Acid. Arsen.**—HYDROCHLORIC SOLUTION OF ARSENIC, SOLUTION OF ARSENIC CHLORIDE]

Solution of Arsenous Acid contains, in each 100 cc., the equivalent of not less than 0.975 Gm. and not more than 1.025 Gm. of As_2O_3.

	Metric	Alternative
Arsenic Trioxide	**10 Gm.**	73 gr.
Diluted Hydrochloric Acid	**50 cc.**	384 min.
Distilled Water, a sufficient quantity, To make	**1000 cc.**	1 pint

Mix the diluted hydrochloric acid with 250 cc. [4 fl. oz.] of distilled water in a flask, add the arsenic trioxide, and boil the liquid until the arsenic trioxide is completely dissolved. Allow the solution to cool, transfer it to a 1000 cc. [1 pint] graduated flask or cylinder, rinse the vessel in which the solution was boiled, with several portions of distilled water, and add the rinsings and

enough distilled water to make the product measure 1000 cc. [1 pint]. Filter if necessary.

This is simply a solution of arsenous acid in diluted hydrochloric acid, no chemical action taking place.

Description and Physical Properties—A clear, colorless liquid without odor.

Solution of Arsenous Acid is acid to litmus paper.

Test for Identity—Hydrogen sulphide T.S. added to Solution of Arsenous Acid produces a lemon-yellow precipitate of arsenic trisulphide, which is completely soluble in ammonium carbonate T.S.

Assay—Measure exactly 20 cc. of Solution of Arsenous Acid and dilute with about 50 cc. of distilled water, dissolve enough sodium bicarbonate in this solution to make it distinctly alkaline (usually about 2 Gm.), and titrate with tenth-normal iodine, using starch T.S. as indicator. Each cc. of tenth-normal iodine corresponds to 0.004948 Gm. of As_2O_3.

This assay is explained on page 1471.

Uses—Solution of arsenous acid is used as an alterative, in doses of three minims (0.2 cc.).

LIQUOR POTASSII ARSENITIS. U.S. Solution of Potassium Arsenite

[**Liq. Pot. Arsen.**—Fowler's Solution, Liquor Arsenicalis Fowleri P. I.]

Solution of Potassium Arsenite contains, in each 100 cc., the equivalent of not less than 0.975 Gm. and not more than 1.025 Gm. of As_2O_3.

	Metric	Alternative
Arsenic Trioxide	**10 Gm.**	73 gr.
Potassium Bicarbonate	**20 Gm.**	146 gr.
Compound Tincture of Lavender	**30 cc.**	230 min.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	1 pint

Boil the potassium bicarbonate and arsenic trioxide in a flask with 100 cc. [1½ fl. oz.] of distilled water until solution is effected. Cool the solution, and transfer it to a 1000 cc. [1 pint] graduated container, rinsing the flask in which the liquid was boiled with several portions of distilled water to make a solution measuring 970 cc. [15 fl. oz.]. Add the compound tincture of lavender, mix thoroughly, and filter if necessary.

$$\underset{\text{potassium bicarbonate}}{2KHCO_3} + \underset{\text{arsenic trioxide}}{As_2O_3} = \underset{\text{potassium metarsenite}}{2KAsO_2} + \underset{\text{carbon dioxide}}{2CO_2} + \underset{\text{water}}{H_2O}$$

When arsenic trioxide is boiled with acid potassium carbonate in concentrated solution, carbon dioxide is evolved, and potassium metarsenite is produced; but, owing to the fact that the salts are soluble in the quantity of water directed in the formula, a solution can be effected without involving any chemical change. The proportionate quantity of potassium bicarbonate was doubled in the U. S. P. 1890. The corresponding British solution (Liquor Arsenicalis) is made from dilute solutions, and its title does not indicate any chemical action.

Description and Physical Properties—A clear or faintly opalescent liquid, having a pink color and a slight odor of lavender. It is alkaline to litmus paper.

Test for Identity—Add to 10 cc. of the Solution an excess of hydrochloric acid and an equal volume of hydrogen sulphide T.S.: a yellow precipitate is produced which is soluble in ammonium carbonate T.S.

Test for Purity—Acidulate 4 cc. of Solution of Potassium Arsenite with diluted nitric acid, add 1 cc. of silver nitrate T.S. and superimpose a layer of ammonia T.S. upon this liquid: no red or reddish-brown color is observed at the line of contact (*arsenate*).

Assay—Measure exactly 20 cc. of Solution of Potassium Arsenite, dilute with 75 cc. of distilled water, acidify the mixture very slightly with diluted hydrochloric acid, then dissolve

in the solution 2 Gm. of sodium bicarbonate, and titrate the resulting liquid with tenth-normal iodine, starch T.S. being used as indicator. Each cc. of tenth-normal iodine corresponds to 0.004948 Gm. of As_2O_3.

Alcohol content, by volume, 1 to 3 per cent.

This assay is explained on page 1471.

History—This preparation was given publicity by Thomas Fowler, M.D., an English physician of the latter part of the eighteenth century. He based it upon a proprietary preparation called "tasteless ague and fever drops" which he analysed with the aid of a local pharmacist named Hughes. He proposed for it the name of *Liquor Mineralis* to conceal the presence of arsenic from the patient.

Uses—Solution of potassium arsenite is largely used as an alterative and tonic in doses of three minims (0.2 cc.).

Antidotes—(See Part XV, on Antidotes).

See "A Century of the United States Pharmacopœia—1820-1920—Liquor Potassii Arsenitis", by H. A. Langehan—(J. A. Ph. A., 1925, pages 408, 507, and 579).

ARSENI IODIDUM. U. S. Arsenous Iodide

[**Arsen. Iod.**—Arsenic Tri-iodide, Arsenic Iodide]

Arsenous Iodide, when dried to constant weight over sulphuric acid, contains not less than 99 per cent of AsI_3 (455.72).

Preparation—In a former official process this iodide was made by a direct combination of the elements as follows:

Take of arsenic trioxide, 60 grains; iodine, 300 grains. Rub the arsenic trioxide in a mortar until reduced to a fine powder; then add the iodine, and rub them together until they are thoroughly mixed. Put the mixture into a small flask or a test tube, loosely stoppered, and heat it very gently until liquefaction occurs. Then incline the vessel in different directions, in order that any portion of the iodine, which may have condensed on its surface, may be returned into the melted mass. Lastly, pour the melted iodide on a porcelain slab, and when it is cold break it into pieces, and keep it in a well-stoppered bottle.

By this process it is difficult to secure entire combination but a purer salt can be made if the pieces are rubbed in a mortar to a powder, chloroform added until as much as possible is dissolved, the solution evaporated, and the crystalline powder washed and dried. A better process consists in pouring a solution of 10 Gm. of arsenic trioxide in 250 cc. of hydrochloric acid into a solution of 51 Gm. of potassium iodide in 40 cc. of hot water, extracting the residue with chloroform, evaporating the solution, and washing and drying the crystalline powder.

Description and Physical Properties—An orange-red, inodorous, crystalline powder, stable when protected from direct sunlight and kept in a cool place.

Caution—Arsenous Iodide is extremely poisonous.

One Gm. of Arsenous Iodide is soluble in about 12 cc. of water at 25° C. with partial decomposition. It is soluble in alcohol, chloroform, ether, and carbon disulphide.

A freshly prepared aqueous solution of the salt is colorless, but upon standing it gradually decomposes with the formation of arsenous and hydriodic acids and becomes yellow, due to the liberation of iodine.

No loss of iodine occurs when dry Arsenous Iodide is heated on a water bath, but at higher temperatures it volatilizes.

Tests for Identity—An aqueous solution of Arsenous Iodide (1 in 50) responds to the reactions for arsenous compounds, page 764, and for iodides, page 575.

Test for Purity—When volatilized, Arsenous Iodide leaves not more than 0.5 per cent of residue.

Assay—Proceed as directed under the assay for iodides, page 575, using about 0.5 Gm. of Arsenous Iodide, previously dried to constant weight over sulphuric acid and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.01519 Gm. of AsI_3.

This assay is explained on page 1462.

Preserve in amber-colored glass stoppered vials, in a cool place, protected from light.

U. S. P. Preparation—Liquor Arseni et Hydrargyri Iodidi.

Uses—The principal use of this salt is in making solution of arsenous and mercuric iodides. The dose is one-twelfth of a grain (0.005 Gm.) as an alterative.

Antidotes—(See Part XV, on Antidotes).

LIQUOR ARSENI ET HYDRARGYRI IODIDI. U. S. Solution of Arsenous and Mercuric Iodide

[Liq. Arsen. et Hydrarg. Iod.—DONOVAN'S SOLUTION]

Solution of Arsenous and Mercuric Iodide is an aqueous solution containing, in each 100 cc., not less than 0.95 Gm. and not more than 1.05 Gm. of AsI_3(455.72), and not less than 0.95 Gm. and not more than 1.05 Gm. of HgI_2 (454.44).

	Metric	Alternative
Arsenous Iodide	**10 Gm.**	**73 gr.**
Red Mercuric Iodide	**10 Gm.**	**73 gr.**
Distilled Water, a sufficient quantity, To make	**1000 cc.**	**1 pint**

Triturate the arsenous iodide and red mercuric iodide in a mortar, add 150 cc. [2½ fl. oz.] of distilled water, and continue the trituration until solution is effected. Filter the solution, and pass sufficient distilled water through the filter to make the product measure 1000 cc. [1 pint]. Mix thoroughly.

It must not be dispensed if darker than pale yellow.

This solution, in which no chemical change occurs, should be of a light straw color; when darker than this, free iodine is probably present, and if a globule of mercury or a few grains of metallic arsenic are dropped into the bottle containing the solution, and the whole well agitated and filtered, the proper color may be restored.

Description and Physical Properties—A clear, colorless or pale yellowish liquid.

Tests for Identity—Lead acetate T.S. produces in Solution of Arsenous and Mercuric Iodide, diluted with 10 volumes of distilled water, a bright yellow precipitate.

Add 5 drops of Solution of Arsenous and Mercuric Iodide to a mixture of about 0.5 Gm. of zinc and 5 cc. of diluted hydrochloric acid in a test tube, and cover the mouth of the test tube with mercuric bromide test paper: a yellow stain appears upon the inner surface of the test paper within one minute.

Solution of Arsenous and Mercuric Iodide responds to the tests for mercury, page 747.

Assay for Arsenous Iodide—Measure accurately 25 cc. of Solution of Arsenous and Mercuric Iodide into a flask, dilute with 25 cc. of distilled water, then dissolve 2 Gm. of sodium bicarbonate in this solution, and titrate with tenth-normal iodine, using starch T.S. as indicator. Each cc. of tenth-normal iodine corresponds to 0.02279 Gm. of AsI_3.

This assay is explained on page 1471.

Assay for Mercuric Iodide—Measure accurately 25 cc. of Solution of Arsenous and Mercuric Iodide into a flask, add 5 cc. of potassium hydroxide T.S. and 5 cc. of formaldehyde T.S. and warm the mixture on a water bath until the mercuric salt has been completely reduced to metallic mercury. Carefully decant the clear, supernatant liquid from the residue of metallic mercury, and wash the mercury carefully by decantation with two successive portions of 25 cc. each of distilled water. Dissolve the residue of metallic mercury in 5 cc. of nitric acid by the application of gentle heat, dilute the solution with 50 cc. of distilled water, add 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.02272 Gm. of HgI_2.

This assay is explained on page 1462.

Preserve in well-filled, amber-colored bottles.

Uses—Solution of arsenous and mercuric iodide is used as an alterative in syphilis and chronic skin diseases. The dose is one and one-half minims (0.1 cc.), largely diluted.

SODII ARSENAS. N. F. Sodium Arsenate

For an account of the preparation and uses of this salt, see page 635. It is now official in the N. F.

SODII ARSENAS EXSICCATUS. N. F. Exsiccated Sodium Arsenate

For the official method of preparation and its uses, see page 636.

LIQUOR SODII ARSENATIS. N. F. Solution of Sodium Arsenate

For the formula, tests and uses, see page 637.

LIQUOR SODII ARSENATIS DILUTUS. N. F. Diluted Solution of Sodium Arsenate

For the formula, tests and uses, see page 637.

LIQUOR AURI BROMIDI ET ARSENI. N. F. Solution of Gold Bromide and Arsenic

[**Liq. Aur. Brom. et Arsen.**—Liquor Auri et Arseni Bromidi, N. F. IV]

	Metric	Alternative
Arsenic Trioxide	**2.50 Gm.**	36½ gr.
Bromauric Acid	**3.25 Gm.**	47 gr.
Bromine	**4.00 Gm.**	58 gr.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Place the arsenic trioxide and bromine in a flask, add 135 cc. [4 fl. oz. 154 min.] of distilled water and heat the mixture gently until solution is effected and all free bromine has disappeared. Then add bromine water, 1 to 2 cc. [15 to 30 min.] at a time, until it is present in slight excess, or until the solution retains a bromide color during thirty minutes. Transfer the solution to a porcelain dish, expel the excess of bromine with the aid of gentle heat, and dilute the solution with distilled water to about 600 cc. [19 fl. oz.]. Dissolve the bromauric acid in this solution and add sufficient distilled water to make the product measure 1000 cc. [2 pints].

Solution of Gold and Arsenic Bromide is a clear liquid having a reddish-brown color. It is acid to litmus paper.

Specific gravity: about 1.004 at 25° C.

Evaporate 10 cc. of the solution at a temperature not exceeding 100° C.: not more than 0.0394 Gm. of residue remains.

Incinerate the residue from 10 cc. of the solution: it leaves not less than 0.129 Gm. of ash corresponding to not less than 0.0104 Gm. of Au.

To 10 cc. of the solution add 5 cc. of tenth-normal silver nitrate and 5 cc. of ammonium carbonate T.S., digest the mixture for ten minutes, on a water bath, then cool and filter. The filtrate, on supersaturating with nitric acid, does not become more than slightly opalescent (chloride).

Uses—It is used chiefly in diabetes. Dose, three minims (0.2 cc.).

One average dose contains the equivalent of about:
0.0005 Gm. or $\frac{1}{125}$ grain of Arsenic Trioxide.
0.0007 Gm. or $\frac{1}{90}$ grain of Bromauric Acid.

Unofficial Compounds of Arsenic

Acetoarsenite of Copper, $Cu(C_2H_3O_2)_2.3Cu(AsO_2)_2$ Paris Green, Schweinfurth's Green	A green powder, used extensively for the destruction of potato bugs by dusting it from the vines. The commercial product is rarely pure. It is very poisonous and the antidotes are the same as for other arsenic poisoning (see Antidote, Part XV)
Arseni Bromidum, $AsBr_3$ Arsenic Bromide	Yellowish-white, poisonous crystals; soluble in water. It is used in medicine and as a chemical reagent
Arseni Chloridum, $AsCl_3$ Arsenic Chloride	A colorless, pungent, oily liquid. When poured into a large quantity of water it deposits arsenous oxide. It is poisonous
Arseni Disulphidum, As_2S_2 Arsenic Disulphide	An orange-red powder, poisonous; insoluble in water. It occurs in nature as the mineral *realgar*. It is used as a pigment and in the manufacture of colored fires
Arseni Trisulphidum, As_2S_3 Arsenic Trisulphide	Commonly called *orpiment*. A yellow or orange-yellow powder, insoluble in water. It is poisonous and is used as a pigment and in medicine
Arsenite of Copper, $Cu_3(AsO_3)_2$ Copper Arsenite, Copper Orthoarsenite, Scheele's Green	Used in the treatment of diarrhea and cholera morbus, also as a remedy for anemia. Dose, one-hundredth to one-twentieth grain (0.0006 to 0.003 Gm.)

Bismuth, Bi; 208.0

The origin of the name *bismuth* is not definitely known. Miners often call the element "wismuth" and it has been suggested that this word comes from "wisse" or "wiese", meaning meadow, because it has often been found in the mines covered with incrustations of various colors resembling a meadow covered with flowers. It is found in the metallic state, and as sulphide, known as *bismuthinite* (Bi_2S_3) and occasionally as the oxide (Bi_2O_3). It is a crystalline, brittle, pulverizable, brilliant metal, having a silver color, with a reddish tint. Its specific gravity is 9.8. It closely resembles metallic antimony in appearance.

Tests for Salts of Bismuth

When dissolved in a slight excess of nitric or hydrochloric acid, bismuth salts yield a white precipitate upon dilution with water. This precipitate is blackened by hydrogen sulphide, and the resulting compound dissolves in a warm mixture of equal parts of nitric acid and water.

BISMUTHI SUBCARBONAS. U.S. Bismuth Subcarbonate

[Bism. Subcarb.—Basic Bismuth Carbonate, Bismuth Oxycarbonate]

Bismuth Subcarbonate is a basic salt of varying chemical composition, which, when dried to constant weight at 100° C., yields upon ignition not less than 90 per cent of bismuth oxide [$Bi_2O_3 = 466.00$].

Preparation—Bismuth subcarbonate may be made as follows:

Take of bismuth in pieces, 2 oz. troy; nitric acid, 8½ oz. troy; ammonia water, 5 fl. oz., sodium carbonate, 10 oz. troy; distilled water, a sufficient quantity. Mix 4½ oz. troy of the nitric acid with 4 fl. oz. of distilled water in a capacious glass vessel, and, having added the bismuth, set the whole aside for twenty-four hours, dilute the resulting solution with 10 fl. oz. of distilled water, stir it thoroughly, and, after twenty-four hours, filter through paper. To the filtered liquid, previously diluted with 4 pints of distilled water, slowly add the ammonia water, constantly stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with two pints of distilled water, and drain it again. Then place the precipitate in a proper vessel, add the remainder of the nitric acid, and afterwards 4 fl. oz. of distilled water, and set the solution aside. At the end of twenty-four hours, filter through paper. Dissolve the sodium carbonate in 12 fl. oz. of distilled water, with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with distilled water until the washings pass tasteless. Lastly, press and dry it on bibulous paper with a gentle heat, and rub it into a powder.

Metallic bismuth generally contains arsenic but by this process any arsenic, if present, will be eliminated. The chemical formula is approximately $[(BiO)_2\,CO_3]_2 + H_2O$.

Description and Physical Properties—A white or pale yellowish-white powder. It is odorless and tasteless, and is stable in the air.

Bismuth Subcarbonate is insoluble in water and in alcohol. It is completely dissolved by nitric and hydrochloric acids with copious effervescence.

Test for Identity—Bismuth Subcarbonate responds to the reactions for bismuth (page 770), and for carbonates (page 589).

Tests for Purity—One Gm. of Bismuth Subcarbonate shows no more *chloride* than corresponds to 1 cc. of fiftieth-normal hydrochloric acid, page 1520.

Dissolve 3 Gm. of the salt in a sufficient quantity (about 4 cc.) of warm nitric acid, and pour the solution into 100 cc. of distilled water: a white precipitate is produced. Filter, evaporate the filtrate on a water bath to 30 cc., again filter the liquid, divide the latter filtrate into portions of 5 cc. each, and subject these several portions to the following tests:

Mix one portion with an equal volume of diluted sulphuric acid: the liquid does not become cloudy (*lead*).

Precipitate another portion with a slight excess of ammonia T.S.: the supernatant liquid does not exhibit a bluish tint (*copper*).

Another portion is not immediately affected by barium nitrate T.S. (*sulphate*).

In another portion, hydrochloric acid produces no precipitate which is insoluble in a slight excess of hydrochloric acid, but soluble in ammonia T.S. (*silver*).

Boil 1 Gm. of Bismuth Subcarbonate with 20 cc. of a mixture of equal volumes of acetic acid and distilled water, cool the solution, and filter. Add 2 cc. of diluted hydrochloric acid, remove the bismuth by the addition of hydrogen sulphide, boil the mixture, and again filter: the latter filtrate leaves not more than 0.005 Gm. of residue on evaporation and gentle ignition (*alkalies or alkali earths*).

Agitate about 0.05 Gm. of Bismuth Subcarbonate with 5 cc. of a solution of equal volumes of distilled water and ferrous sulphate T.S. and cautiously superimpose the mixture upon 5 cc. of concentrated sulphuric acid: no brownish-red zone forms at the line of contact of the two liquids (*nitrate*).

The residue resulting from the ignition of 2 Gm. of Bismuth Subcarbonate does not respond to Bettendorf's test for *arsenic*, page 1512.

Assay—Dry about 1 Gm. of Bismuth Subcarbonate to constant weight at 100° C., weigh accurately in a tared porcelain crucible, ignite at a red heat, and weigh the resulting bismuth oxide. The residue of bismuth oxide (Bi_2O_3) corresponds to not less than 90 per cent of the original weight of Bismuth Subcarbonate taken.

This assay is explained on page 1477.

Preserve protected from light.

Uses—Bismuth Subcarbonate is used for its protective and antacid effect in inflammations of the stomach and bowels. It is also given in large doses (two ounces) for rendering the alimentary canal opaque to X-ray. It is employed for the same purposes as the subnitrate, but is to be preferred to the subnitrate in mixtures containing carbonates, as the acidity, often noticed in the subnitrate, frequently causes decomposition or explosion in capsules, pills, etc.; the latter, however, is much more frequently used.

The dose is from five to fifteen grains (0.3 to 1 Gm.).

BISMUTHI SUBGALLAS. U.S. Bismuth Subgallate

[**Bism. Subgal.**—Basic Bismuth Gallate, Bismuth Oxygallate, Dermatol]

Bismuth Subgallate is a basic salt of varying chemical composition, which, when dried to constant weight at 100° C., yields upon ignition not less than 52 per cent and not more than 57 per cent of bismuth oxide [$Bi_2O_3 = 466.00$].

Preparation—Bismuth subgallate may be made by dissolving bismuth subnitrate in diluted acetic acid and precipitating the solution with gallic acid, but a more convenient and rapid method is that of Thibault, which is as follows: Bismuth trioxide is triturated with water, and an excess of pure gallic acid added, continuing the trituration until the color of the mixture has changed to a greenish-yellow. It is allowed to stand twenty-four hours, washed and dried. The chemical formula is approximately $Bi(OH)_2C_7H_5O_5$.

Description and Physical Properties—An amorphous, bright yellow powder. It is odorless and tasteless, and is stable in the air.

Bismuth Subgallate is practically insoluble in water, alcohol, and ether. It is readily dissolved with decomposition by warm, moderately dilute hydrochloric, nitric, or sulphuric acid: insoluble in very dilute mineral acids. It is readily dissolved by solutions of alkali hydroxides, forming a clear, yellow liquid, which rapidly changes to a deep red.

Tests for Identity—When heated to redness, Bismuth Subgallate at first chars, leaving finally a yellow residue, which is blackened by hydrogen sulphide T.S. A solution of this residue in a slight excess of warm nitric or hydrochloric acid produces a white turbidity when added to twenty-five volumes of distilled water.

Agitate thoroughly about 0.1 Gm. of Bismuth Subgallate with an excess of hydrogen sulphide T.S., filter, boil the filtrate to remove the dissolved gas, cool, and add one drop of ferric chloride T.S.: a blue-black color is produced.

Tests for Purity—Shake 1 Gm. of Bismuth Subgallate with 20 cc. of alcohol for one minute filter, and evaporate the filtrate to dryness on a water bath: not more than 0.005 Gm. of residue remains (*free gallic acid*).

Boil 1 Gm. of Bismuth Subgallate with 20 cc. of a mixture of equal parts of acetic acid and distilled water, cool the solution, and filter. Free the filtrate from bismuth by the addition of hydrogen sulphide, boil the mixture, and again filter: the latter filtrate leaves not more than 0.005 Gm. of residue on evaporation and gentle ignition (*alkalies or alkali earths*).

Mix thoroughly about 0.05 Gm. of Bismuth Subgallate with 5 cc. of diluted sulphuric acid and 5 cc. of ferrous sulphate T.S., filter the mixture, and carefully superimpose the filtrate, without mixing, on 5 cc. of concentrated sulphuric acid, page 1542, in a test tube: no brownish-red zone forms immediately (*nitrate*).

Ignite 3 Gm. of Bismuth Subgallate in a porcelain crucible, cool, and cautiously add, drop by drop, just sufficient nitric acid to dissolve the residue when it is warmed. Evaporate the solution

to dryness, again ignite, and cool. Cautiously dissolve this residue in just sufficient nitric acid by the aid of gentle heat, concentrate the solution to about 4 cc., pour it into 100 cc. of distilled water, filter, evaporate the filtrate on a water bath to 20 cc., again filter, and divide this filtrate into portions of 5 cc. each. These portions do not respond to the tests for *lead, copper or silver* under *Bismuthi Subcarbonas.*

The residue resulting from the ignition and subsequent treatment of 2 Gm. of Bismuth Subgallate, as described in the following test, meets the requirements of Bettendorf's test for *arsenic*, page 1512.

Assay—Ignite in a porcelain crucible about 1 Gm. of Bismuth Subgallate, previously dried to constant weight at 100° C. and accurately weighed, allow it to cool, and add nitric acid to the residue, drop by drop, warming until complete solution has been effected. Evaporate this solution to dryness, carefully ignite at red heat, and weigh the resulting bismuth oxide. The residue of bismuth oxide (Bi_2O_3) corresponds to not less than 52 per cent and not more than 57 per cent of the original weight of Bismuth Subgallate taken.

This assay is explained on page 1477.

Preserve protected from light.

Uses—Bismuth subgallate has been used internally in diarrhea, in doses of eight to fifteen grains (0.5 to 1 Gm.); externally as an application to wounds and ulcerations and in the treatment of eczema.

BISMUTHI SUBNITRAS. U. S. Bismuth Subnitrate

[**Bism. Subnit.**—Basic Bismuth Nitrate, Bismuth Oxynitrate]

Bismuth Subnitrate is a basic salt of varying chemical composition, which, when dried for twenty-four hours over sulphuric acid, yields upon ignition not less than 79 per cent of bismuth oxide [$Bi_2O_3 = 466.00$].

Preparation—This important salt may be made by the former official process, as follows:

Take the bismuth, in pieces, 2 oz. troy; nitric acid, 8½ oz. troy; sodium carbonate, 10 oz. troy; ammonia water, 5 fl. oz.; distilled water, a sufficient quantity. Mix 4½ oz. troy of the nitric acid with 4 fl. oz. of distilled water, in a capacious glass vessel, and, having added the bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with 10 fl. oz. of distilled water, stir it thoroughly, and, after twenty-four hours, filter through paper. Dissolve the sodium carbonate in 20 fl. oz. of distilled water with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of bismuth nitrate, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with distilled water until the washings pass tasteless, and drain as completely as possible. Then place the moist precipitate in a capacious vessel, gradually add the remainder of the nitric acid, and afterwards 4 fl. oz. of distilled water, and set the solution aside. At the end of twenty-four hours, filter through paper, and to the filtered liquid, previously diluted with 4 pints of distilled water, slowly add the ammonia water, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with 2 pints of distilled water, drain it again, and press out as much of the liquid as possible. Lastly, dry it upon bibulous paper with a gentle heat, and rub it into powder.

The formation of bismuth subnitrate may be explained by the following equations:

$$\underset{\text{bismuth}}{Bi_2} + \underset{\text{nitric acid}}{8HNO_3} = \underset{\text{bismuth nitrate}}{2Bi(NO_3)_3} + \underset{\text{water}}{4H_2O} + \underset{\text{nitrogen dioxide}}{N_2O_2}$$

then

$$\underset{\text{bismuth nitrate}}{5Bi(NO_3)_3} + \underset{\text{water}}{8H_2O} = \underset{\text{bismuth subnitrate}}{4BiONO_3.H_2O} + \underset{\text{bismuth nitrate}}{Bi(NO_3)_3} + \underset{\text{nitric acid}}{8HNO_3}$$

The chemical formula is approximately $Bi(OH)_2NO_3$.

Description and Physical Properties—A white, slightly hygroscopic powder.

Bismuth Subnitrate is practically insoluble in water, insoluble in alcohol, but is readily dissolved by hydrochloric or nitric acid.

Tests for Identity—Bismuth Subnitrate responds to the reactions for bismuth (page 770), and for nitrates (page 551).

When heated to redness, it evolves brown vapors of nitrogen oxides, leaving a yellow residue.

When brought in contact with moistened blue litmus paper, Bismuth Subnitrate shows a slightly acid reaction.

Tests for Purity—Boil 1 Gm. of Bismuth Subnitrate with 20 cc. of a mixture of equal volumes of acetic acid and distilled water. Cool and filter. Add 2 cc. of hydrochloric acid, remove the bismuth by the addition of hydrogen sulphide, boil the mixture, and filter: the filtrate leaves not more than 0.005 Gm. of residue on evaporation and gentle ignition (*zinc, alkali earths or alkalies*).

Boil about 0.1 Gm. of the salt with 5 cc. of sodium hydroxide T.S.: no odor of ammonia is perceptible nor does the vapor turn moistened red litmus paper blue.

One Gm. of the salt shows no more *chloride* than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid, page 1520.

The residue resulting from the ignition of 2 Gm. of the salt meets the requirements of Bettendorf's test for *arsenic*, page 1512.

Add 3 Gm. of Bismuth Subnitrate to 3 cc. of warm nitric acid: no effervescence occurs (*carbonate*), and no residue remains (*insoluble foreign salts*). A white precipitate is produced when this solution is poured into 100 cc. of distilled water. Now filter, evaporate the filtrate on a water bath to 30 cc., again filter the liquid, and divide the new filtrate into portions of 5 cc. each. These portions do not respond to the tests for *lead, copper, sulphate or silver* under *Bismuthi Subcarbonas*.

Assay—Dry about 1 Gm. of Bismuth Subnitrate over sulphuric acid for twenty-four hours, weigh accurately in a tared porcelain crucible, ignite at red heat, and weigh the resulting bismuth oxide. The residue of bismuth oxide (Bi_2O_3) corresponds to not less than 79 per cent of the original weight of Bismuth Subnitrate taken.

This assay is explained on page 1477.

Preserve protected from light.

N. F. Preparations—Glyceritum Bismuthi; Magma Bismuthi; Unguentum Resorcinolis Compositum.

Uses—Bismuth subnitrate is largely used in intestinal disorders; less frequently as a dusting powder. The dose is from three to ten grains (0.2 to 0.6 Gm.).

BISMUTHI SUBSALICYLAS. U.S. Bismuth Subsalicylate

[**Bism. Subsalicyl.**—Basic Bismuth Salicylate, Bismuth Oxysalicylate]

Bismuth Subsalicylate is a basic salt of varying chemical composition, which, when dried to constant weight at 100° C., yields upon ignition not less than 62 per cent and not more than 66 per cent of bismuth oxide [$Bi_2O_3 = 466.00$].

Preparation—Bismuth Subsalicylate is apt to be an unstable salt. It may be made by Thibault's process, as follows: 15 Gm. of crystallized bismuth nitrate dissolved in nitric acid are precipitated by an excess of solution of sodium hydroxide. After boiling, the whole of the amorphous, white, hydrated oxide is transformed into yellow crystallized anhydrous oxide; it is then thoroughly washed, and 10 Gm. of salicylic acid, rubbed up with 200 cc. of water, are added. The whole is then left on the water bath, and when there are no more opaque, yellow needles of anhydrous oxide left, it is thoroughly washed with cold alcohol, and dried in an oven. The chemical formula is approximately $Bi(OH)_2C_7H_5O_3$.

Description and Physical Properties—A white, or nearly white, amorphous or crystalline powder. It is odorless, and is stable in the air.

Bismuth Subsalicylate is practically insoluble in cold water. Upon prolonged boiling with water, a portion of the salicylic acid passes into solution with the formation of a more basic bismuth salicylate. When treated with a slight excess of warm nitric or hydrochloric acid, it is decomposed, a flocculent white precipitate of salicylic acid separating.

Tests for Identity—When heated, Bismuth Subsalicylate at first chars, and above 300° C. leaves a yellow residue, which is blackened by hydrogen sulphide. This residue responds to the reactions for bismuth, page 770.

Agitate about 0.1 Gm. of Bismuth Subsalicylate with a solution of five drops of ferric chloride T.S. in 10 cc. of distilled water: a deep violet-blue coloration is produced.

Tests for Purity—Agitate 1 Gm. of Bismuth Subsalicylate with 20 cc. of chloroform, filter the liquid, and evaporate the filtrate to dryness: not more than 0.005 Gm. of residue remains (*free salicylic acid*).

Ignite 3 Gm. of Bismuth Subsalicylate in a porcelain crucible, cool, and cautiously add, drop by drop, just sufficient nitric acid to dissolve the residue when it is warmed. Pour the acid solution into 100 cc. of distilled water, filter, evaporate the filtrate on a water bath to 30 cc., again filter, and divide the filtrate into portions of 5 cc. each. These portions do not respond to the tests for *lead, copper, sulphate, or silver* under *Bismuthi Subcarbonas*.

Boil 1 Gm. of Bismuth Subsalicylate with 20 cc. of a mixture of equal parts of acetic acid and distilled water, cool the solution, and filter. Free the filtrate from bismuth by the addition of hydrogen sulphide, boil the mixture, and again filter: the latter filtrate on evaporation and ignition leaves not more than 0.005 Gm. of residue (*alkalies or alkali earths*).

Triturate about 0.05 Gm. of Bismuth Subsalicylate with 0.1 Gm. of sodium salicylate and 5 cc. of distilled water, and superimpose the mixture upon 5 cc. of concentrated sulphuric acid, page 1542: no pink or brownish-red zone is observed at the line of contact (*nitrate*).

The residue resulting from the ignition and subsequent treatment of 2 Gm. of Bismuth Subsalicylate as described in the test below, meets the requirements of Bettendorf's test for *arsenic*, page 1512.

Assay—Dry about 1 Gm. of Bismuth Subsalicylate to constant weight at 100° C. and weigh accurately. Ignite in a porcelain crucible, and, after cooling, add 5 cc. of nitric acid, drop by drop, to the residue, warming until solution has been effected. Evaporate this solution to dryness, and carefully ignite it at red heat and weigh the resulting bismuth oxide. The residue of bismuth oxide (Bi_2O_3) corresponds to not less than 62 per cent and not more than 66 per cent of the original weight of Bismuth Subsalicylate taken.

This assay is explained on page 1477.

Preserve protected from light.

Uses—This salt is used as an intestinal antiseptic and protective in doses of from five to fifteen grains (0.3 to 1 Gm.).

MAGMA BISMUTHI. N.F. Bismuth Magma

(U. S. P. IX)

[**Magma Bism.**—Milk of Bismuth, Cream of Bismuth]

Bismuth Magma yields not less than 5.6 Gm. and not more than 6.2 Gm of Bi_2O_3 (466.00), in each 100 cc., corresponding to not less than 7 Gm. of bismuth subnitrate in each 100 cc.

	Metric	Alternative
Bismuth Subnitrate	**80 Gm.**	2 oz. av. 293 gr.
Nitric Acid	**120 cc.**	3 fl. oz. 403 min.
Ammonium Carbonate	**10 Gm.**	146 gr.
Ammonia Water,		
Distilled Water, each, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Mix the bismuth subnitrate with 60 cc. [1 fl. oz. 442 min.] of distilled water and 60 cc. [1 fl. oz. 442 min.] of nitric acid in a flask and agitate, warming gently until solution is effected. Pour this solution, with constant stirring, into 5000 cc. [10 pints] of distilled water containing 60 cc. [1 fl. oz. 442 min.] of nitric acid. Dilute 480 cc. [15 fl. oz. 173 min.] of ammonia water with 4000 cc. [8 pints] of distilled water in a glazed or glass vessel of at least 12,000 cc. [3 gallons] capacity. Dissolve the ammonium carbonate in this solution and then quickly pour the bismuth solution into it with constant stirring. If the mixture is not distinctly alkaline, add sufficient ammonia water to make it so and allow it to stand until the precipitate has subsided, then pour or siphon off the supernatant liquid and wash the precipitate twice with distilled water, by decantation. Afterwards transfer the magma to a strainer of close texture, arranged in a percolator so as to provide continuous washing with distilled water, the outlet tube being elevated to prevent the surface of the magma from becoming dry, and allow the operation to proceed until the washings cease to react with phenolphthalein T.S. Then drain the moist magma, transfer it to a graduated vessel and add sufficient distilled water to make the product measure 1000 cc. [2 pints]. Mix thoroughly, transfer to bottles and stopper tightly.

Official Description—A thick, white, opaque liquid containing bismuth hydroxide and bismuth subcarbonate in suspension in water.

Reaction—Neutral to litmus paper and phenolphthalein, T.S.

Test for Identity—One cc. of hydrochloric acid added to 1 cc. of Bismuth Magma produces a clear solution. Pour the clear solution into 10 volumes of distilled water: a white precipitate is produced.

Assay—Evaporate to dryness 10 cc. of Bismuth Magma, accurately measured, and ignite the residue to constant weight: the residue of Bi_2O_3 weighs not less than 0.56 Gm. and not more than 0.62 Gm.

This assay is explained on page 1477.

Uses—It is used for the same purposes as bismuth subnitrate in doses of one fluidrachm (4 cc.).

GLYCERITUM BISMUTHI. N. F. Glycerite of Bismuth

The formula, tests, and uses will be found on page 302.

LIQUOR BISMUTHI. N. F. Solution of Bismuth

[Liq. Bism.]

	Metric	Alternative
Glycerite of Bismuth	125 cc.	4 fl. oz.
Alcohol	125 cc.	4 fl. oz.
Distilled Water, a sufficient quantity, To make	1000 cc.	2 pints

Mix the glycerite of bismuth with 700 cc. [22 fl. oz. 192 min.] of distilled water, then add the alcohol and finally sufficient distilled water to make the product measure 1000 cc. [2 pints].

Description and Tests—Solution of Bismuth is a clear, colorless liquid, almost odorless, having a slightly acidulous, sweetish, saline taste, and an acid reaction.

Add to 5 cc. of the Solution, two or three drops of diluted hydrochloric acid: a gelatinous, white precipitate is formed. This precipitate is immediately soluble in an excess of diluted hydrochloric acid.

No precipitate of basic bismuth salt is formed on the addition of ammonia T.S.

A dark brown precipitate is formed in the presence of an excess of diluted hydrochloric acid upon the addition of 5 cc. of hydrogen sulphide T.S. to 5 cc. of the Solution.

Uses—This is an astringent and is used in diarrhea but should never be given when acute inflammation is present. The dose is about one fluidrachm (4 cc.).

Unofficial Salts of Bismuth

Bismuthi Betanaphtholas (U. S. P. IX) Bismuth Betanaphthol	A buff-colored to grayish-brown, amorphous powder; odorless and tasteless. Nearly insoluble in water and alcohol. Used as an intestinal antiseptic in doses of 8 to 15 grains (0.5 to 1 Gm.)
Bismuthi Bromidum, $BiBr_3$ Bismuth Bromide	A yellowish-white, crystalline powder, decomposed by water, yielding an insoluble basic salt. It should be kept in a dry place
Bismuthi Chromas, $3Bi_2O_3.2CrO_3$ Bismuth Chromate	An orange-yellow, amorphous powder; insoluble in water. It is used as a pigment
Bismuthi Citras, $BiC_6H_5O_7$ Bismuth Citrate	Bismuth citrate, rendered soluble by the presence of ammonium citrate. Shining, pearly, or translucent scales or a white powder, becoming opaque with loss of ammonia upon exposure to air. It is very soluble in water and is used as an astringent, being generally prescribed in solution. The dose is from 1 to 3 grains (0.06 to 0.2 Gm.)
Bismuthi et Ammonii Citras (U. S. P. IX) Bismuth and Ammonium Citrate	
Bismuthi et Ferri Citras Bismuth and Iron Citrate	A soluble compound of variable composition but containing about forty per cent each of bismuth and iron citrates. It is used for dyspepsia
Bismuthi et Potassii Tartras Bismuth and Potassium Tartrate	A fine, granular, white powder; soluble in water. This compound is being used in the treatment of syphilis. The dose is from 1½ to 3 grains (0.1 to 0.2 Gm.). *Potassium Bismuth Tartrate* is more fully described, in the New and Non-official Remedies of 1925
Bismuthi Iodosubgallas Bismuth Oxyiodogallate Airol	A grayish-green, bulky powder; decomposed by water. It is used externally as a dusting powder for wounds and ulcers, also in ointments
Bismuthi Lactas Bismuth Lactate	A white, crystalline powder; slowly soluble in water. Its uses in medicine are similar to those of bismuth subnitrate
Bismuthi Methylene Digallas Bismal	A grayish-blue, bulky powder; insoluble in water. It is used as an intestinal astringent in doses of from 1½ to 5 grains
Bismuthi Oleas, $Bi(C_{17}H_{33}COO)_3$ Bismuth Oleate	A yellowish-brown, soft, granular mass, composed of bismuthous oxide and oleic acid. An olive-oil suspension of this compound called *Oleo-Bi-Roche* is described in the New and Non-official Remedies of 1925
Bismuthi Oxalas, $Bi_2(C_2O_4)_3.15H_2O$ Bismuth Oxalate	A white, granular powder; insoluble in water. It is dissolved by acids
Bismuthi Oxidum, Bi_2O_3 Bismuth Oxide	A heavy, yellow powder; insoluble in water. Its uses and dose are similar to those of bismuth subnitrate
Bismuthi Oxychloridum, $BiOCl$ Bismuth Oxychloride	Also called bismuthyl chloride and pearl white. It is a white, lustrous, crystalline powder; insoluble in water. It is used in face powders and pigments
Bismuthi Phosphas, $BiPO_4$ Bismuth Phosphate	A white powder; insoluble in water. It is used as an intestinal antiseptic and astringent. Dose, 3 to 8 grains

Unofficial Salts of Bismuth—*Continued*

Bismuthi Tannas Bismuth Tannate	A yellow powder; insoluble in water. It is used as an intestinal astringent and antiseptic.
Bismuthi Tribromphenas, N. N. R. Bismuth Tribromphenol Xeroform	A basic bismuth tribromphenate, of variable composition. An amorphous, yellow, nearly tasteless and odorless powder; slightly soluble in water, alcohol, chloroform, liquid petrolatum, and vegetable oils. A non-irritating, non-toxic, antiseptic, a substitute for iodoform. Internally for gastro-intestinal catarrh. Dose, 15 to 45 grains (1 to 3 Gm.) for adults. Marketed by Schering and Glatz, Inc.
Bismuthi Valeras Bismuth Valerate	A white powder having the disagreeable odor of valeric acid. It is insoluble in water and is used as a sedative and antispasmodic.

BISMOSOL, N. N. R.—A sterilized solution of potassium sodium bismuthotartrate (containing 35 per cent bismuth [Bi]) 10 Gm.; piperazine, 0.3 Gm., in an aqueous solution of glucose, to make 100 cc. A pale yellow, syrupy liquid.

Uses—Bismosol is proposed as a means of obtaining the systemic effects of bismuth in the treatment of syphilis.

Dose, administered intramuscularly in doses of 1 cc. every two to seven days until twenty doses have been given. After an intermission of one month, a second course may be given.

Manufactured by Powers-Weightman-Rosengarten Company.

CHAPTER LVI

GOLD AND PLATINUM

Au; 197.2 Pt; 195.2

Salts of these precious metals are not in the primary official lists, but bromauric acid is recognized in the N. F. Several gold salts enter the unofficial materia medica, and platinum salts are employed as test solutions. The name *gold* means yellow in several languages. The name *platinum* is from "platina", the diminutive form in the Spanish for silver, referring to its white color resembling silver. Gold and platinum are both found native in the free state, but not abundantly in many places. Gold is usually found alloyed with silver or copper while platinum is generally found in the same ore with metals of the palladium—platinum group. Latin names for these metals are Aurum and Platinum.

Tests for Gold Salts

Solutions of gold salts yield a purple coloration or precipitate with stannous chloride T.S.

Tests for Platinum Salts

1. If hydrogen sulphide or ammonium sulphide is added to a solution of platinic chloride, a brown precipitate of platinic sulphide will be produced, soluble in excess of ammonium sulphide.

2. If a solution of potassium chloride is added to a solution of platinic chloride acidulated with hydrochloric acid, a yellow precipitate (double chloride) will be formed.

ACIDUM BROMAURICUM. N. F. Bromauric Acid

[Acid. Bromaur.]

It contains $HAuBr_4.5H_2O$ (607.97) corresponding to not less than 32 per cent of gold, Au.

Description and Physical Properties—Bromauric Acid occurs as dark red-brown, flat, needle-shaped crystals, or as irregular, coarse, granular masses; odorless, and having a metallic and acid taste. Permanent in the air when pure; when chloride is present the salt is deliquescent.

Bromauric Acid melts at about 27° C.

It is very soluble in water and in alcohol.

Its aqueous solution is strongly acid to litmus, and yields with silver nitrate T.S. a yellowish-white precipitate, insoluble in nitric acid and but slightly soluble in ammonia water.

Tests for Purity—Ignite 0.1 Gm. of Bromauric Acid, heat the resulting residue of gold with 5 cc. of nitric acid, add 15 cc. of distilled water and filter; no weighable residue remains on evaporating the filtrate and igniting.

Dissolve 0.2 Gm. of Bromauric Acid in 10 cc. of distilled water, add 16 cc. of tenth-normal silver nitrate V.S. and 12 cc. of ammonium carbonate T.S., digest the mixture for ten minutes on a water bath, then cool and filter. The filtrate, on supersaturating with nitric acid, does not become more than slightly opalescent (*chloride*).

Bromauric Acid is decomposed on exposure to red heat and leaves a residue of metallic gold equivalent to not less than 32 per cent of the weight taken.

Preserve it in glass-stoppered, amber-colored bottles.

N. F. Preparation—Liquor Auri et Arseni Bromidi.

Uses—It is used in the preparation of the N.F. solution. The dose is one-tenth grain (0.006 Gm.).

Unofficial Salts of Gold

Auri Bromidum, $AuBr_3$ Gold Bromide	An unstable dark powder; very soluble in water. It should be kept from light. It is used in medicine as an anti-epileptic, anodyne, and nervine
Auri Chloridum, $AuCl_3$ Gold Chloride	A yellow, crystalline powder; readily soluble in water. It is used in photography and in electro-plating, and should be kept dry and unexposed to light
Auri et Sodii Chloridum Gold and Sodium Chloride	A mixture of equal parts of anhydrous gold chloride and anhydrous sodium chloride. An orange-yellow powder, very hygroscopic when exposed to damp air. It is readily soluble in water. It is used in photography, in decorating porcelain, and in staining glass. It is also used in medicine as an alterative and nervine. Dose, $\frac{1}{12}$ to $\frac{1}{4}$ grain (0.005 to 0.015 Gm.). Because of its instability it should be kept in well-stoppered, amber-colored vials
Auri Iodidum, AuI_3 Gold Iodide	A greenish-yellow powder; soluble in water and easily decomposed by heat, yielding iodine vapors and a residue of gold. It is used in tubercular diseases. Dose, $\frac{1}{60}$ to $\frac{1}{8}$ grain (0.001 to 0.008 Gm.)

PART V

ORGANIC CHEMISTRY AND ORGANIC CHEMICAL SUBSTANCES

CHAPTER LVII

THEORY OF ORGANIC CHEMISTRY

ORGANIC chemistry was for a long time considered to be the chemistry of substances produced or evolved by living tissues or organs. In the early days of scientific chemistry it was believed that the chemical compounds which are distinctive of organic chemistry could only be produced by vital action. In 1828 Wöhler, a German chemist, succeeded in transforming the inorganic compound ammonium cyanate, NH_4CNO, into the organic compound urea, NH_2CONH_2, by the simple process of heating.

This broke down the artificial barrier that had existed between the subdivisions of inorganic and organic substances. Since that time there have been produced thousands of syntheses of organic compounds first discovered in natural sources, and thousands of other organic compounds exist of which no counterparts whatever have been found in nature. The line of demarcation between the two is not very distinct, but since practically all of the so-called organic compounds contain carbon, and the great majority of them carbon and hydrogen, organic chemistry is frequently called the chemistry of the carbon compounds, or the chemistry of the hydrocarbons and their derivatives.

The chemistry of vital processes has never been solved, although much light has been thrown upon it in recent years by researches in plant chemistry and in physiological chemistry.

Carbon, hydrogen, oxygen, and nitrogen are the elements most frequently found in organic compounds; sulphur and phosphorus are present in complex protein compounds found in animal tissues particularly. Iron is found in hemoglobin, an essential constituent of the blood, iodine in thyroxin, the active principle of the thyroid gland. Potassium, calcium, magnesium, and fluorine are found in certain vital tissues and fluids.

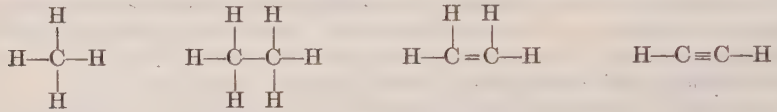
These few elements are apparently the ones essential to vital action. In addition to these, certain other elements have been introduced in preparing organic substances that are of purely synthetic origin. The complexity of organic compounds may be appreciated by a glance at a few empirical formulas of typical organic compounds:

$C_{10}H_{16}$ terpene, from essential oils.
$C_{16}H_{16}O$ camphor.
$C_{10}H_{14}N_2$ nicotine, from tobacco.
$C_{20}H_{24}O_2N_2$ quinine, from cinchona.
$C_{26}H_{45}NSO_7$ taurocholic acid, from bile.
$C_{42}H_{84}NPO_9$ lecithin, from eggs.
$C_{34}H_{34}FeN_4O_5$ hæmatin, from blood.
$C_{54}H_{64}MgN_4O_6$ chlorophyll, from green vegetable tissues.
$C_{11}H_{10}NO_3I_3$ thyroxin, from the thyroid gland.

Proximate principles are organic compounds which exist in natural sources, as morphine in opium, sugars in the juices of fruits and in other vegetable

tissues, and olein in oils and fats. The separation of these principles in a state of purity is called proximate analysis. The *ultimate principles* or constituents composing a substance are the elements themselves and the determination of elemental composition is called *ultimate analysis.* Both proximate and ultimate analyses are highly specialized branches of chemical research, requiring knowledge of fundamental chemical principles, skill in the technic of carrying out chemical reactions, and apparatus adapted to the particular line of investigation.

The formulas of organic compounds are written according to the same principles of valence as those of inorganic compounds previously discussed. The great number of carbon compounds, many having identical empiric formulas but differing in structural relationships, is explained by the fact that the carbon atom, whose valence is invariably four, as in CH_4, can, by single, double, or treble linkings with other carbon atoms in the same molecule, apparently show a valence of three as in C_2H_6, two as in C_2H_4, or even one as in C_2H_2. It requires a study of the graphic or structural formulas of these respective compounds to appreciate their exact character as shown by the following:



methane, CH_4 ethane, C_2H_6 ethylene, C_2H_4 acetylene, C_2H_2

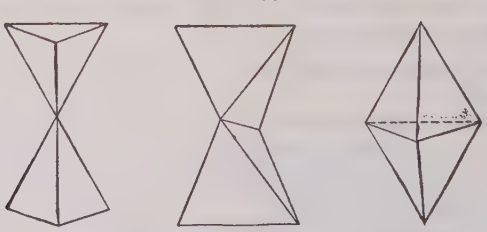
The fact that these linkings or common bonds of attachment may be produced in two or three directions at once, and may be extended in open formation, or in a closed series, as in a chain, makes it apparent that there are almost infinite possibilities of variation.

The ordinary structural formula which has thus far been used represents the atoms as arranged upon the same plane. This form of representing a compound conserves practically all of the requirements for an understanding of the composition of substances and is the one generally used. Inasmuch as molecules unquestionably occupy space, it is sometimes desirable to formulate them on a three dimensional system in order to illustrate certain differences of structure that would not otherwise be easily shown.

In order to do this the carbon atom is assumed to have the shape of a tetrahedron.

The four apexes of this distinctively shaped solid correspond to the four valences manifested by carbon. By placing two of these tetrahedral forms to-

FIG. 433

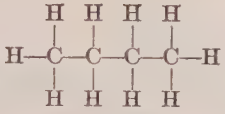


Stereochemic formulas

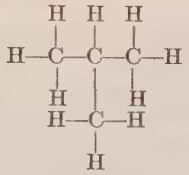
gether in the three possible ways in which apexes may be connected, we see illustrations of the four compounds previously shown, from a slightly different viewpoint (see Fig. 433). These are called stereochemic formulas.

In the compounds of carbon, as has previously been stated, combinations are frequently encountered in which the empiric formula is almost meaningless because of the existence of from two to sometimes nearly a dozen compounds which have exactly the same ultimate composition. Where two or more compounds have the same empiric formula but differ in certain properties they are called *isomers*, and the condition is called *isomerism*. True isomerism is where the compounds belong to the same class or group. The names of such compounds as show a close structural relationship to one or more others is prefixed by the Greek syllable *iso* meaning *the same*.

Thus in the hydrocarbon butane, C_4H_{10}, we have two possibilities as shown by the following graphic formulas:



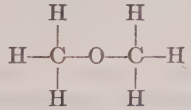
normal butane



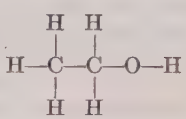
isobutane

Such differences give rise to distinctive usages in writing formulas and to the nomenclatural possibilities of defining them. Thus normal propane is written $CH_3CH_2CH_3$, and is called di-methyl methane, while isopropane is written $CH_3CHCH_3CH_3$ and is also called tri-methyl methane, for reasons which will be appreciated later.

Another form of isomerism is *metameric isomerism* or *metamerism*. This term is used to express the relationship between compounds which have the same empiric composition but which do not belong to the same class. This is illustrated by the formula C_2H_6O, which is applicable to either methyl oxide or ethyl alcohol, as illustrated by the following graphic and structural formulas:



methyl oxide—condensed structural formula $(CH_3)_2O$



ethyl alcohol—condensed structural formula C_2H_5OH

In this kind of isomerism the compounds are simply referred to as isomeric, but the prefix *iso* is not attached to either as in the preceding instance.

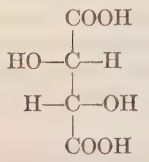
A kind of isomerism which differs from both of the preceding is where one compound is related to the other in having a formula which is a simple multiple of that of the original compound. This is called *polymeric isomerism*, and the compounds of the higher molecular weight are called *polymers*. They are sometimes distinguished from the original compound by the prefix *para*, which, however, has another distinctive meaning in the majority of cases and will be explained under the cyclic compounds to be considered later.

Thus CH_3CHO, often written C_2H_4O, is acetaldehyde, sometimes called simply *aldehyde*. Its polymeric isomer is $(CH_3CHO)_3$, often written $C_6H_{12}O_3$, and is called *paraldehyde*.

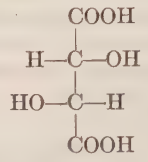
Where isomerism is dependent upon the spatial relation of the constituent atoms in complex molecules, it can only be properly represented by the stereochemic formulas recently discussed. This is called *stereoisomerism*, and

stereoisomers are of common occurrence, as, for example, in the optically active and inactive varieties of lactic and tartaric acids.

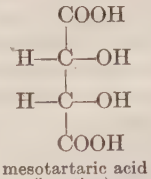
Thus tartaric acid is known in the forms illustrated below:



levotartaric acid



dextrotartaric acid



mesotartaric acid (inactive)

The racemic variety is also optically inactive, since it is made up of equal parts of dextro- and levotartaric acid molecules.

Stereoisomers are of opposite effect upon polarized light, *i. e.*, where one is dextrorotatory, the other is levorotatory. Where, as is frequently the case, the two stereoisomeric forms are combined, an optically inactive form of the compound results, which is known as the *racemic* form.

In organic chemistry even more than in inorganic chemistry, it is necessary to deal with radicles or groups of atoms which confer distinctive properties upon molecules containing them.

Some of these occur so frequently that it is desirable to describe them here, and illustrate some of the compounds in which they are found.

Hydroxyl (OH). This radicle is found in both organic and inorganic compounds. The presence of one or more hydroxyl groups in a compound is indicated in the correct nomenclature by the termination "ol," *e. g.*, phenol, C_6H_5OH; methanol, CH_3OH; glycerol, $C_3H_5(OH)_3$.

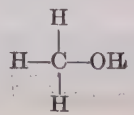
The hydrogen of the OH group in organic compounds of this class is replaceable by positive elements as K and Na.

Carboxyl (COOH). This group is characteristic of organic acids. The hydrogen of this group is replaceable by positive elements and radicles to form salts and esters. The basicity of an organic acid is dependent upon the number of such groups present. As examples may be cited acetic acid, CH_3COOH, which is monobasic; tartaric acid, $(CHOH)_2$ $(COOH)_2$ which is dibasic, and citric acid, $(CH_2)_2COH(COOH)_3$, which is tribasic.

Aldehyde (CHO). This group is found in a large number of organic compounds. The hydrogen is joined to the carbon atom and is not replaceable by positive elements or groups. Example: formaldehyde, HCHO and acetaldehyde, CH_3CHO. Aldehydes are sometimes written with the distinctive group, as COH. This is incorrect, because such an arrangement of the atoms is characteristic of the formula of a tertiary alcohol.

Aldehydes stand midway as oxidation products between alcohols and the organic acids. The name comes from the initial syllable of the term *al*cohol and the first two syllables of the word *dehyd*rogenatum, because aldehydes are produced by the removal of hydrogen from alcohols. A study of the reactions that are involved in the formation of a series of such related compounds will serve to illustrate the foregoing points and will also serve to show how fascinatingly interesting the possibilities of organic chemistry become to one who takes the trouble to thoroughly understand the underlying principles.

The graphic structural formula of methyl alcohol is:



The structural formula generally used for such a molecule would be HCH_2OH. The ordinary method of writing the formula, which has become a matter of custom, is CH_3OH. When this compound is oxidized, it does not take up oxygen, but instead it loses hydrogen, as shown by the following equation:

$$\underset{\text{methyl alcohol}}{HCH_2OH} + \underset{\text{oxygen}}{O} = \underset{\text{formaldehyde}}{HCHO} + \underset{\text{water}}{H_2O}$$

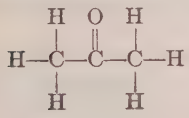
When formaldehyde in turn undergoes oxidation, it does so by the addition of an atom of oxygen which converts the aldehydic group into the carboxyl group as follows:

$$\underset{\text{formaldehyde}}{HCHO} + \underset{\text{oxygen}}{O} = \underset{\text{formic acid}}{HCOOH}$$

These reactions illustrate the intermediate position which aldehydes occupy between alcohols and acids.

Aldehydic groups confer certain distinctive reacting powers upon the molecules in which they occur, particularly in the carbohydrates.

Ketonic Group—This is a distinctive method of linking rather than a radicle such as we have been considering. It is characterized by having a carbon atom united to oxygen by two of its bonds and to two other carbon atoms by the remaining bonds, thus:



Example, acetone, CH_3COCH_3 (dimethylketone). This group, like the aldehyde group, gives to the molecule containing it certain distinctive reacting properties.

Amino (NH_2)—This group is characteristic of the simplest primary amines and confers basic properties, the basicity being in proportion to the number of such groups present. When the amino group is associated with a positive group, the compound is basic and is known as an *amine* (sometimes shortened to *amin*). When the amino is associated with a negative group the resulting compound may be neutral or acid and is called an *amide* (sometimes shortened to *amid*).

Examples: $C_2H_5NH_2$—ethylamine.
CH_3CONH_2—acetamide.

Both amines and amides are derived ammonias in which the hydrogen of NH_3 has been partly or wholly replaced by hydrocarbon or acid groups, respectively. In a *primary amine* one may conceive of one atom of hydrogen of NH_3 having been substituted, as in ethylamine. In a *secondary amine*, two thirds of the NH_3 are substituted, as in diethylamine $(C_2H_5)_2NH$. Such compounds are sometimes called *imines* or *imides* having the characteristic group known as *imido* (NH). *Tertiary amines* are also known in which all three of the hydrogen atoms of NH_3 are substituted. The disagreeable smelling compound found in herring brine known as trimethylamine $(CH_3)_3N$, is an example of this group.

The *open chain, fatty* or *aliphatic* hydrocarbons and their derivatives are the simplest of the organic compounds and will be the first to be considered. A hydrocarbon is a compound containing only carbon and hydrogen and the compounds of this type are very numerous.

The *open chain hydrocarbons* are sometimes called the *aliphatic* or *fatty* hydrocarbons, because many of their derivatives are found in the vegetable and

animal fats and oils. At the same time there are many open chain compounds that do not show any resemblance to the fats or oils in their properties.

The closed chain hydrocarbons are derivatives of coal-tar benzene (benzol), C_6H_6, and will be considered later.

The simplest open chain hydrocarbon is methane, CH_4, in which a single atom of carbon has each of its four valence bonds satisfied with an atom of hydrogen. This is known as a saturated compound. If all or part of the hydrogen in CH_4 is substituted by an element or group of elements having the proper equivalence, the saturation will not be disturbed. Hence, CH_3Cl, CH_2Cl_2, $CHCl_3$ and CCl_4 are all saturated organic compounds referable to CH_4 as the starting point. By successive subtractions of H from CH_4 a series of radicles is obtained which are not fully saturated and in which the valence is equivalent to the number of hydrogen atoms removed. CH_3 is therefore a monad radicle, CH_2 is a dyad and CH a triad. These are called unsatisfied hydrocarbon radicles and from each of these may be obtained derivatives and compounds comparable to analogous compounds in inorganic chemistry. Chlorides, bromides, hydroxides, sulphates, sulphides, oxides, etc., may be produced from these radicles or the radicles themselves may act as substituting groups.

Each of these hydrocarbons and each of the derived radicles may constitute a member of what is known as a homologous series. A homologous series is a series of compounds in which each member differs from the members on either side of it by the constant factor, CH_2.

Examples are given in the following table:

Saturated hydrocarbons	Unsatisfied radicles			Unsaturated hydrocarbons
1.	2.	3.	4.	5.
General Formula	General Formula	General Formula	General Formula	General Formula
$C_nH_{2n} + 2$	$C_nH_{2n} + 1$	C_nH_{2n}	$C_nH_{2n} - 1$	$C_nH_{2n} - 2$

3. This column also applies to a series of unsaturated hydrocarbons known as the olefines, with names ending in -ylene in place of *-ene*.

Valence O	Valence I	Valence II	Valence III	Valence O
Methane, CH_4	Methyl, CH_3	Methene, CH_2	Methenyl, CH	Acetylene or Ethine, C_2H_2
Ethane, C_2H_6	Ethyl, C_2H_5	Ethene, C_2H_4	Ethenyl, C_2H_3	Propine, C_3H_4
Propane, C_3H_8	Propyl, C_3H_7	Propene, C_3H_6	Propenyl, C_3H_5	Butine, C_4H_6
Butane, C_4H_{10}	Butyl, C_4H_9	Butene, C_4H_8	Butenyl, C_4H_7	Pentine, C_5H_8
Pentane, C_5H_{12}	[1]Pentyl, C_5H_{11}	Pentene, C_5H_{10}	Pentenyl, C_5H_9	Hexine, C_6H_{10}
Hexane, C_6H_{14}	Hexyl, C_6H_{13}	Hexene, C_6H_{12}	Hexenyl, C_6H_{11}	

[1] NOTE—Pentyl is usually called *amyl* in organic compounds.

The foregoing table stops with *hexane* of the paraffin series. It might be continued at great length, as members are known as far up in the series as *dimyricyl* ($C_{60}H_{122}$).

It will be noticed upon studying the above table that the groups with odd valences end in "yl" and that in the terminations of the hydrocarbons the vowels a, e, and i, are utilized in their regular order.

It is not to be understood that all of the members of these fundamental series are of common occurrence or even that all of them have been prepared, but most of them are known and the others could doubtless be prepared if necessity arose. They are of importance to the student as starting points of derivatives, many of which are of great economic value and importance in pharmacy.

A brief consideration of some of them will serve to emphasize this fact.

Paraffins, from *parvum affinis* (little affinity). The members of this series are saturated molecules not easily affected by chemical agents. Many of them have been found in natural gas and petroleum.

Methane—CH_4, the first member of the paraffin series, is a colorless, odorless gas occurring in natural gas, which, in some instances is nearly pure methane. It is also produced by the slow decomposition of cellulose, and is the gas which forms in the bottom of marshes and stagnant pools, whence the name *marsh gas*. When mixed with air, as is sometimes observed in coal mines, it constitutes the deadly *fire damp*, which is the frequent cause of explosions in such mines. The invention by Sir Humphrey Davy of the safety lamp which bears his name was for the purpose of minimizing this danger.

Ethane, C_2H_6; *propane*, C_3H_8; *butane*, C_4H_{10}; *pentane*, C_5H_{12}; *hexane*, C_6H_{14}; and *heptane*, C_7H_{16} are all found in petroleum, and some of them occur in nearly pure form in *cymogene*, *rhigolene*, *petroleum benzin*, *gasolene*, and *kerosene*. The hydrocarbons from C_8H_{18} to $C_{15}H_{32}$ are present in lubricating oils, and from $C_{16}H_{34}$ to $C_{20}H_{42}$ in *petrolatums* and in the so-called *paraffin waxes*.

There is a mathematical gradation of specific gravities, boiling points, and other physical properties from the lowest to the highest member of the series. The derivatives of the paraffin hydrocarbons are frequently produced by the direct action of chlorine or bromine, the halogen derivatives then being taken as the starting point for derivatives of other types.

The halogen derivatives themselves are frequently compounds of considerable importance. The chlorine substitution products of methane may be taken to illustrate this fact and also the possibilities of nomenclature of organic compounds which is a very important branch of their study.

Methane CH_4.
Monochlormethane (*methyl chloride*) CH_3Cl.
Dichlormethane (*methene chloride*) CH_2Cl_2.
Trichlormethane (*methenyl chloride*) $CHCl_3$.
(chloroform)
Tetrachlormethane (*carbon tetrachloride*) CCl_4.

If the italicized names in the above list are carefully studied and the principle of their formation thoroughly understood, the student will be able to appreciate the scientific basis of the nomenclature of the simpler organic compounds and will realize its possibilities.

Alkyls or monohydric alcohol series—This series consists of monad radicles. It is sometimes called the *methyl* series because *methyl* is the simplest member.

This series yields oxides called ethers, halogen derivatives called alkyl halides, salts that are called esters, hydroxides called alcohols, carbonyl derivatives called ketones, etc.

The relationship of these to each other may be appreciated by studying the following possibilities of modification and transformation along these lines. The alkyl radicles, ethyl and methyl, have been selected as yielding examples of importance in the following group.

Ethers—*Ethyl oxide*, $(C_2H_5)_2O$, commonly called *"ether"*, a member of the important generic group of *ethers* which may consist of simple ethers, as

illustrated above, or of mixed ethers, as $(CH_3)(C_2H_5)O$, which is called methyl-ethyl ether.

Alkyl Halides—*Ethyl chloride*, C_2H_5Cl. (This is really a type of an ester in which an inorganic acid unites with the radicle.)

Esters—*Ethyl acetate*, $C_2H_5C_2H_3O_2$. (This is sometimes incorrectly called "acetic ether".) The esters correspond to the "salts" of inorganic chemistry. Many are of official importance.

Hydroxides—*Ethyl hydroxide*, C_2H_5OH, commonly called *"alcohol"*, and a member of the important generic group of alcohols. It is also called *ethanol.*

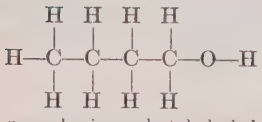
Ketones—*Dimethyl ketone*, CH_3COCH_3, commonly called *acetone* and a member of the important generic group of ketones. It is also called *propanone.*

Aldehydes—*Methyl formaldehyde*, or *ethyl aldehyde*, CH_3CHO, commonly called *aldehyde* and a member of the important generic group of *aldehydes.* It is also called *acetaldehyde* because upon oxidation it yields acetic acid.

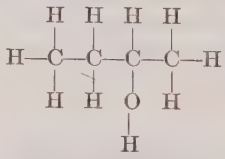
Acids—*Methyl formic acid*, CH_3COOH, commonly called *acetic acid.* This is also called *ethanoic acid.*

The lower members of the alcohol series are capable of existing in only one form. There are no isomers of methyl or ethyl alcohol. There are two possible isomers of propyl alcohol, three of butyl alcohol and the complexity increases upon ascending the scale. In order to distinguish certain types of the isomeric alcohols they are designated as *primary*, *secondary*, or *tertiary.* In primary alcohols the CH_2OH group is joined to only one other carbon atom. In secondary alcohols the group CHOH is joined to two carbon atoms. In tertiary alcohols the group COH is joined to three carbon atoms.

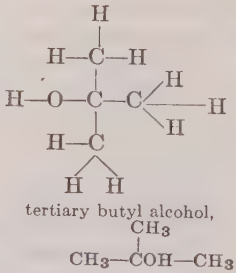
Illustrations of all three of these forms are found in the structural formulas of three of the butyl alcohols.



normal primary butyl alcohol, $CH_2CH_2CH_2CH_2OH$



secondary butyl alcohol, $CH_3CH_2CHOHCH_3$



tertiary butyl alcohol, $(CH_3)_3COH$

The COH group of the tertiary alcohols is trivalent and has the structure $\equiv C-(OH)$; it must not be confused with the aldehyde group CHO, which is monovalent and in which the hydrogen is united directly with the carbon, as in

$$-\underset{\displaystyle H}{\overset{|}{C}}=O.$$

The alcohols containing two OH groups are known as *dihydric alcohols* or *glycols.* Each of these alcohols yields *two* acids upon oxidation. Thus ethene glycol gives the following acids:

$$C_2H_4(OH)_2 + O_2 = \underset{\text{glycolic acid}}{CH_2OHCOOH} + H_2O$$

$$C_2H_4(OH)_2 + O_4 = \underset{\text{oxalic acid}}{(COOH)_2} + H_2O$$

Other derivatives of the dihydric alcohols of importance in pharmacy are *lactic acid* which is an oxidation product of the 1:2 *propene glycol*, and *succinic*

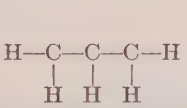
acid which is an oxidation product of 1:4 *butene glycol*. The first named acid is monobasic and the second is dibasic.

The oxygen of the alcohols may be replaced by other elements, as sulphur. For instance, ethyl alcohol, C_2H_5OH, has a corresponding sulphur compound, C_2H_5SH, which is really *ethyl hydrosulphide* or *ethyl sulphydrate*, but which is called *ethyl mercaptan*, the term being used in the generic sense also as in the case with the terms alcohol and aldehyde. The mercaptans when oxidized form sulphonic acids. Sulphur compounds corresponding to ethers are known, such as $(C_2H_5)_2S$, ethyl sulphide. The essential oils of garlic, mustard, horse radish, asafetida, etc., contain organic sulphides which are usually strongly odorous or irritating compounds. The *mustard gas* of the World War was the halogenated organic sulphide, dichlordiethyl sulphide $(C_2H_4Cl)_2S$.

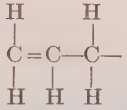
Olefins—The olefin series of hydrocarbons of the table on page 784, is capable of yielding the same corresponding series of derivatives, such as alcohols, esters, aldehydes, acids, etc., that have been discussed under the paraffin series.

Malic acid, $CH_2CHOH(COOH)_2$, *tartaric acid*, $CHOHCHOH(COOH)_2$, and *citric acid*, $(CH_2)_2COH(COOH)_3$, are all regarded as types of the hydroxy or alcohol acids of this series.

The Methenyl series is composed of triad radicles. The most important member of this group is propenyl, C_3H_5, also called *glyceryl*. The hydroxide of this radicle, $C_3H_5(OH)_3$, is *glycerol* (*glycerin*). Most of the common fats and oils are esters of *glyceryl*, with one or more of the higher fatty acids, as oleic, palmitic, or stearic. *Allyl*, C_3H_5, is isomeric with *glyceryl*, but differs in the fact that it has a valence of one, due to a variation in structure as shown by the following:



glyceryl



allyl

The Acetylene series of hydrocarbons is of little pharmaceutical importance.

Among the important of the more complex derivatives of the open chain hydrocarbons are the *carbohydrates*, which derive their name from the fact that they contain the three elements carbon, hydrogen, and oxygen, the latter two being in the same proportion in which they exist in water, namely, two atoms of hydrogen to one atom of oxygen. The limitation of composition, however, is no longer strictly applicable, as some true carbohydrates are known, in which this ratio of hydrogen to oxygen does not exist. The term, however, is too well fixed in the nomenclature of chemistry to be displaced.

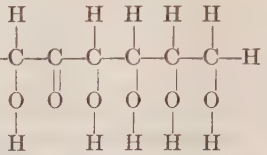
Starch and cellulose $(C_6H_{10}O_5)_n$, dextrose $C_6H_{12}O_6$, and sucrose $C_{12}H_{22}O_{11}$, are typical carbohydrates.

The carbohydrate molecules are very complex. They contain hydroxyl groups as the predominating factor, although aldehyde and ketone groups are frequently present.

The structural formulas of *dextrose* and *levulose* will serve for illustration of these facts:

Dextrose 
This is written in graphic form $CH_2OHCHOHCHOHCHOHCHOHCHO$ and the aldehydic group CHO is clearly apparent.

Levulose



This is written in graphic form $CH_2OHCOCHOHCHOHCHOHCH_2OH$ and the ketonic group CO is equally evident.

The *closed chain, cyclic,* or *aromatic hydrocarbons* are connected into one or more closed series or chains. Three atoms of carbon, of course, is the smallest number that can form such a chain. When all of the atoms composing the chain are of one kind the structure is known as *isocyclic.* When the chain includes elements of different kinds it is called *heterocyclic.* The closed chain hydrocarbons having the same number of carbon atoms as those of the open chain series are generally distinguished in name by adding the prefix "cyclo".

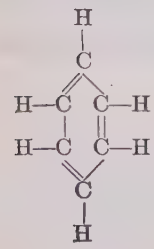
Thus the simplest isocyclic hydrocarbon is *trimethene,*

which is isomeric with the olefin hydrocarbon, propylene C_3H_6, and the former is called *cyclopropane.*

The most important and interesting of the isocyclic compounds is the series of hydrocarbon compounds containing six carbon atoms commonly known as the *benzene* series from the name of its fundamental member.

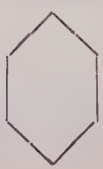
Benzene, C_6H_6, was first prepared in 1825 by Faraday from coal gas, later by Mitscherlich in 1834 by the destructive distillation of a benzoate (whence the name benzene) and subsequently in 1845 by Hofmann from coal tar, which has since been the principal source of its supply.

The chemical nature of benzene was not comprehended until 1865 when Kekule suggested its cyclic structure and its six latent valences, as illustrated by the following structural formula, which is generally accepted as satisfying the requirements from both theoretical and practical standpoints.



The double linkings between alternate carbon atoms are latent valences which increase the possibilities of preparing derivatives.

For the sake of convenience the cumbersome detailed structural formula as given above is usually replaced by a simple oblong hexagon which is understood to mean C_6H_6.

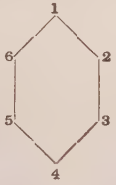


When any ordinary substitution of the hydrogen atoms occurs, such as by the OH group in the formation of phenol from benzene, it is simply represented as

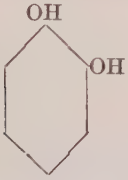
which means C_6H_5OH.

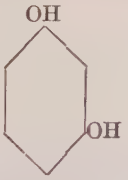
The position of the substituting element or group is immaterial in the case of a single substitution, but for the sake of uniformity it is usually placed at the upper angle of the hexagon as just shown.

When two of the hydrogen atoms of benzene are replaced, however, three isomeric compounds are possible. To assist in indicating the possible differences, the angles of the benzene ring, as it is called, are distinguished by imaginary numbers starting with one at the top and going around in clockwise order, thus:



Substitution of two of the hydrogen atoms of benzene can take place in three different ways, as shown by the following structural formulas.

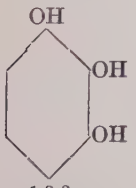




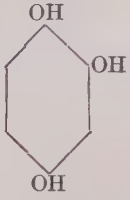
Each of these three compounds is entitled to the name dihydroxybenzene, but to distinguish them further the figures of substitution positions are added to the name, or the respective prefixes "ortho", "meta", and "para" are employed.

Thus the first of the three compounds given above is either called orthodihydroxybenzene or 1-2 dihydroxybenzene. The second is called metadihydroxybenzene or 1-3 dihydroxybenzene. The third is called paradihydroxybenzene or 1-4 dihydroxybenzene. The second of the isomers in the foregoing case is the well known resorcinol.

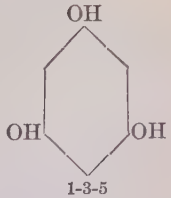
Substitution of three hydrogen atoms of benzene by three similar atoms or groups also gives rise to three isomers which are distinguished as follows:



1-2-3
consecutive or adjacent



1-2-4
unsymmetric



1-3-5
symmetric

The first of the foregoing isomers is 1-2-3 trihydroxybenzene (commonly known as pyrogallol), the second is 1-2-4 trihydroxybenzene, and the third is 1-3-5 trihydroxybenzene (commonly known as phloroglucin).

The isomeric forms are often designated by placing the letters v, a, or s before the name, these letters coming from the words vicinal, asymmetrical and symmetrical, respectively.

In order that the student may familiarize himself with the use of the ring symbols as they are called, and to afford an opportunity to become acquainted with the nomenclature of the cyclic compounds, a number of illustrations are given most of which are of compounds of importance in pharmacy.

C_6H_5OH

hydroxybenzene, phenylhydroxide, phenol

$C_6H_5NO_2$

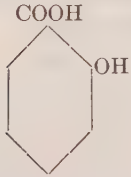
nitrobenzene, oil of mirbane

C_6H_5COOH

carboxybenzene, benzoic acid

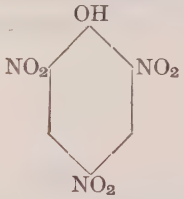
C_6H_5CHO

benzaldehyde



$C_6H_4OHCOOH$

1-2 hydroxybenzoic acid, orthohydroxybenzoic acid, salicylic acid



$C_6H_2OH(NO_2)_3$

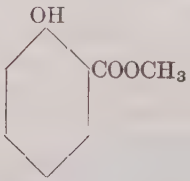
2-4-6 trinitrohydroxybenzene, trinitrophenol, picric acid

$C_6H_5CH_3$

methyl benzene, toluene

1–4 $C_6H_4OHHSO_3$

1-4 hydroxybenzene sulphonic acid, paraphenolsulphonic acid

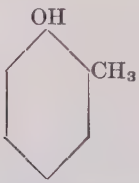


$C_6H_4OHCOOCH_3$

1-2 hydroxymethylbenzoate, methyl salicylate

$C_6H_5NH_2$

aminobenzene, aniline



$C_6H_4OHCH_3$

orthohydroxymethylbenzene, orthocresol

$C_6H_5CH_2OH$

phenylcarbinol, benzyl alcohol

A careful study of the foregoing formulas will show that the classes of compounds, and the nomenclatural possibilities are exactly analogous to those discussed under the open chain hydrocarbons.

So far as homologous series are concerned there is exact parallelism. Benzene is considered as the first member of a series of the general formula C_nH_{2n-6} of which the following are the lower members of the series.

C_6H_6—*Benzene.*

C_7H_8—*Methylbenzene,* $C_6H_5CH_3$ *Toluene.*

C_8H_{10}—*Dimethylbenzene,* $C_6H_4(CH_3)_2$ *Xylene.*

C_9H_{12}—*Trimethylbenzene,* $C_6H_3(CH_3)_3$.

$C_{10}H_{14}$—*Tetramethylbenzene,* $C_6H_2(CH_3)_4$.

These homologues of benzene are all associated with it in the more volatile fractions of coal tar.

For convenience in naming compounds, C_6H_5 is sometimes referred to as *phenyl,* and the OH group is sometimes referred to as "oxy", or "hydroxy". Thus C_6H_5OH is either *phenyl hydroxide, hydroxybenzene,* or *oxybenzene* or *phenol.* Phenol is a generic as well as a specific name. The *phenols* are nucleus hydroxy derivatives of benzene and are distinguished by the terms *mono-di-* or *tri-* hydric *phenols,* depending upon the number of hydroxyl groups present.

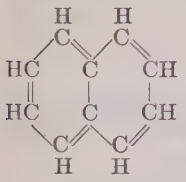
Phenol, C_6H_5OH, is *monohydric; resorcinol,* $C_6H_4(OH)_2$ 1:2, is *dihydric;* and *pyrogallol,* $C_6H_3(OH)_3$ 1:2:3, is *trihydric.*

The phenols must not be confused with the *aromatic alcohols* in which the hydroxyl substitution occurs not in the nucleus but in the side chain, as a substituting group is called. Thus C_6H_5OH is a phenol and $C_6H_5CH_2OH$ is an alcohol.

The *terpenes* are cyclic hydrocarbons having the general formula $(C_5H_8)_n$. They carry one or more latent valences. They are classified as *hemiterpenes,* C_5H_8; *terpenes,* $C_{10}H_{16}$; *sesquiterpenes,* $C_{15}H_{24}$; *diterpenes,* $C_{20}H_{32}$; *polyterpenes,* $(C_{10}H_{16})_n$.

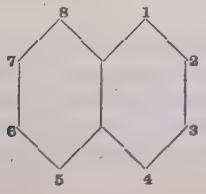
Camphors are oxygenated terpene derivatives. Ordinary camphor, $C_{10}H_{16}O$, and borneol, $C_{10}H_{18}O$, are examples.

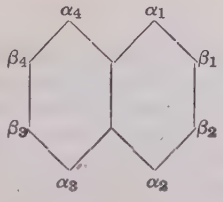
Naphthalene, $C_{10}H_8$, consists of a double ring in which two benzene nuclei are held together by two common carbon atoms. All but the linking atoms are saturated with hydrogen, as shown by the following graphic formula.



It is usually expressed in a manner comparable to that used for benzene, as

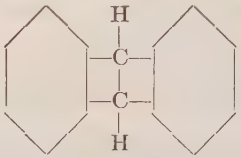
The *naphthalene ring* is oriented or numbered in the same manner as the benzene ring and certain positions are given Greek letter designations as shown by the following two diagrams:





The *naphthols* are hydroxy derivatives of naphthalene, just as the phenols are hydroxy derivatives of benzene. The empiric formula of the simplest naphthol is $C_{10}H_7OH$. There are two isomers known. They are called *alpha naphthol* and *beta naphthol*. Both are important in pharmacy. Their structural formulas may be deduced from the foregoing explanation of the positions in the naphthalene ring.

Anthracene $C_{14}H_{10}$ is an important coal tar fraction having a distinctive structure as follows:



Diphenyl $(C_6H_5)_2$ consists of independent rings joined at one point, as in the following example.

Many of its derivatives, through *benzidin*, which is diamidodiphenyl, are valuable dyes.

When two atoms of nitrogen are joined by two bonds and the remaining bonds are joined to hydrocarbon radicles, the compound so formed is called an *azo compound*. Example, $C_6H_5-N=N-C_6H_5$, *azobenzene*.

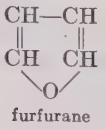
When the N_2 group is attached by one bond to a hydrocarbon radicle and by the other to an acid radicle, or to hydroxyl, there is formed a *diazo compound*. Example, $C_6H_5-N=N\,HSO_3$, *diazobenzenesulphonic acid*.

When an atom of oxygen occurs between the nitrogen atoms of an azo compound as in *azobenzene*, an *azoxy compound* results. Example, $C_6H_5NON\,C_6H_5$, *azoxybenzene*.

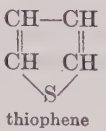
When one of the bonds of each nitrogen atom in an azo compound is united to a hydrogen atom, a *hydrazo compound* results. Example, $C_6H_5NHNHC_6H_5$, *hydrazobenzene*.

The hydrazines are related to the diazo compounds except that the union between the nitrogens is by one bond and that one of the nitrogen atoms is attached to hydrogen, only, by its remaining two bonds. Example, $C_6H_5HN\text{-}NH_2$, phenylhydrazine.

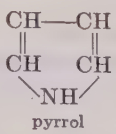
Heterocyclic compounds are ring compounds in which other elements are present in addition to the carbon and the hydrogen. The most commonly occurring and best known examples of this type are as follows:



furfurane



thiophene



pyrrol

The principal example of the six-membered heterocyclic rings is *pyridine*, C_5H_5N, in which the ring nucleus contains 5 carbon atoms and 1 nitrogen atom. A heterocyclic double linked ring compound is found in *quinoline*, which bears the same relationship to pyridine that naphthalene does to benzene. Both pyridine and quinoline are the starting point of homologous series, in which are found members of importance.

This condensed presentation of the principles of organic chemistry is introduced as a fitting preface to the detailed consideration of the many important therapeutic agents belonging to this class. In the following pages, however, the compounds are considered in the usual groups only when the substances composing them have similar chemical and physical properties. The opening chapters are devoted to *cellulose* and its derivatives; then *benzoic acid and its compounds and derivatives*; next *coloring principles*; followed by *organometallic compounds*; then *starch*, and the allied products, gums, mucilages, etc.; then the *sugars* and the products derived from them as the result of decomposition and fermentation, *alcohol*, *ether*, etc., including the various synthetic products which are derived from organic bases or acids. Following these the *acid saccharine fruits*, with the important acids which they contain, are considered, and then the products obtained from them and from other plants; *i. e.*, the *volatile oils*, *oleo-resins*, *resins*, *gum-resins*, and *balsams* naturally following each other, the classification being based upon the character of prominent constituents found in the drugs; *astringents*, *cathartics*, etc., being grouped together. Drugs containing *alkaloids* are among the last organic compounds to be considered. The alkaloids are very complex, and most of them are powerful poisons. The plan thus begins with elementary substances, like cellulose, starch, and gum, and leads by regular progression to the most powerful compounds in the materia medica, the alkaloids.

Following the alkaloids the subject of *vitamines* and afterwards medicinal products from animal source are given due consideration.

A sharp distinction is made between the U. S. P. and N. F. drugs and preparations, the latter usually following the former. Full botanical descriptions have not been included for vegetable or animal drugs, the reader being referred to the U. S. P. or N. F. monographs for the details of plant structure, microscopic descriptions, etc.

Many unofficial drugs and preparations are also included, and the arrangement enables the student to distinguish the more important compounds at a glance, and they can be studied together or separately, at will.

CHAPTER LVIII

THE CELLULOSE GROUP

Cellulose—$(C_6H_{10}O_5)_n$[1]

Cellulose—The woody fiber of plants, which forms the skeleton or framework for the vegetable tissues, is termed *cellulose*, or *cellulin*. During the natural growth of the plant, the cells become filled with coloring matter, starch, gums, organic acids, fixed oils, volatile oils, glucosides, alkaloids, and other active principles peculiar to the particular plant, and these give to the plant physical properties which render it useful in medicine. Pharmacy teaches the various methods of extracting the *valuable principles* from plants and leaving behind or eliminating by appropriate methods those which are inert. Cellulose constitutes the greater part of the inert residues (see Percolation).

The term *lignin* was formerly applied to cellulose; indeed, three words, *lignin*, *cellulin*, and *cellulose*, were used synonymously; a distinction, however, is sometimes made, the substances which are found adhering to the cellulose skeleton of plants and vegetable tissues being called *lignin* so that lignin may be considered an alteration product of cellulose. The latter is less digestible than cellulose, and it is believed by Payen and others to vary from it somewhat in chemical composition. *Fungin*, from fungi, *hordein*, from barley, *medullin*, from the pith of various plants, *pollenin*, from pollen granules, are special forms of cellulose. The lignin in plant chemistry is estimated and calculated as "*crude fiber*".

Cellulose is seen in a pure form in raw cotton, the hairs of the seed of various species of Gossypium, and in many other vegetable products. It is the most useful and valuable substance obtained from plants; fabrics like cotton, linen, or hemp goods are made on an immense scale from cellulose. Ashless filter paper is a prepared form of practically pure cellulose. When pure, cellulose is white, translucent, unalterable in the air, and has the specific gravity of 1.5. It is insoluble in water, alcohol, ether, petroleum benzin, and oils, but is dissolved by concentrated zinc chloride solution, and in an ammoniacal solution of copper oxide, and this latter fact has been taken advantage of to form many useful articles by partially dissolving a woven cotton material and rolling or pressing it into any desired shape. Artificial silk is produced from cellulose by various methods. It is now called *rayon*, *celamese*, or *lustron*. In one method for preparing *artificial silk*, a gelatinous *hydrocellulose* is precipitated from an ammoniacal copper oxide solution by acid, alkali salts or sugar solutions, this hydrocellulose is then redissolved in a mixture of caustic soda and carbon disulphide, and reprecipitated, in a gelatinous state, by salts, the precipitate being forced through minute perforations to form filaments which are spun into thread. By another method a substance known as *viscose*, which is *sodium-cellulose dithiocarbonate*, is prepared by treating cellulose with strong alkali, macerating the *mercerized cellulose* so produced in carbon disulphide and then treating with an acid solution of sodium sulphate. The resulting gelatinous mass is then formed into threads which are washed, dried, treated

[1] The formula for cellulose is given with an unknown factor, $(C_6H_{10}O_5)n$, because its molecular weight has never been determined. For the *determination of a molecular weight* a substance must be capable of being vaporized, melted, or dissolved without decomposition. As cellulose is one of the few organic bodies which cannot be changed in its physical form in this way, its molecular weight (or a multiple of the same) is deduced from its decomposition and hydrolysis.

to remove excess of sulphur, bleached, and subsequently wound into skeins from which are woven the viscose fabrics. When cellulose is treated with strong sulphuric acid or phosphoric acid, it is converted into dextrin. If the mixture is diluted with water and heated, dextrose is produced. If cellulose in the form of unsized paper is passed through a mixture made from two parts of sulphuric acid of specific gravity 1.840 and one part of water (*both by measure*), and the whole *cooled to* 15° C. (59° F.), the valuable product known as *parchment paper* is produced, amyloid being formed. The strips of paper should be well washed after parchmentizing by passing them through a dilute solution of ammonia and water. This paper is useful as a dialyzing medium; it forms, when perfect, an excellent septum (see Dialysis).

When cellulose is treated with acetic anhydride in the presence of sulphuric acid, esters called *cellulose acetates* are produced. Cellulose acetate is soluble in chloroform and also in a number of other organic solvents. The solutions may be utilized for the production of threads to form fabrics (*cellulose acetate silk*) or *sheets*, known as *cellophane*, which may be used for bottle caps or for wrapping packages to make a transparent, damp-proof wrapper. Cellulose acetate sheets are used for the non-inflammable films of the moving picture industry.

Cellulose is employed in the form of filtering paper, in muslin and cotton cloth strainers, for surgical bandages, paper, lint, etc. When cellulose is treated with a mixture of nitric and sulphuric acids, pyroxylin, or guncotton, is produced.

GOSSYPIUM PURIFICATUM. U.S. Purified Cotton

[Gossyp. Purif.—Absorbent Cotton]

The hairs of the seed of cultivated varieties of *Gossypium herbaceum* Linné, or of other species of *Gossypium* (Fam. *Malvaceæ*), freed from adhering impurities and linters, and deprived of fatty matter.

Purified cotton constitutes cellulose in one of its purest forms. For a long time one of the most important uses of this valuable staple, that of an absorbent and substitute for sponge, was neglected, because a trace of fatty matter was permitted to remain, which coated the filaments and prevented the cotton from absorbing liquids freely and uniformly. The so-called absorbent cotton of commerce was introduced, and it soon became an important product. This is cotton freed from the trace of fatty matter by boiling it in a weak alkaline solution to remove fat, rinsing it in a weak solution of chlorinated lime to bleach it, dipping it into a very dilute solution of hydrochloric acid, and then thoroughly rinsing it with pure water; the cotton, having been thoroughly dried, is then carded. The loss is about 10 per cent.

A form of cotton which has been purified but from which the oil has not been removed is known as *non-absorbent cotton*. This is of special value for stoppering flasks or test tubes containing liquids to be sterilized by live steam, as it does not readily absorb moisture.

Description and Physical Properties—White, soft, fine filaments, appearing under the microscope as hollow, flattened and twisted bands, spirally striate and slightly thickened at the edges. It is odorless and almost tasteless.

Purified Cotton is insoluble in ordinary solvents, but is soluble in ammoniated cupric oxide T.S.

Tests for Purity—Purified Cotton, previously compressed in the hand, when thrown on the surface of water at about 25° C., readily absorbs it and sinks.

Ash: not more than 0.2 per cent.

Thoroughly saturate about 10 Gm. of Purified Cotton with 100 cc. of distilled water, then with the aid of a glass rod press out two 25 cc. portions of the water into white porcelain dishes. Add to one portion three drops of phenolphthalein T.S. and to the other portion one drop of methyl orange T.S.: no pink color develops in either portion (*alkali or acid*).

Pack 10 Gm. of Purified Cotton in a narrow percolator, extract with ether, until the percolate measures 200 cc. and evaporate to dryness: the residue does not exceed 0.6 per cent (*fatty matter*).

Pack 10 Gm. of Purified Cotton in a narrow percolator, and extract with alcohol until the percolate measures 50 cc.: when observed downward through a column 20 cm. in depth, the percolate may show a yellowish color, but no blue or green tint (*dyes*).

Place 10 Gm. of Purified Cotton in 200 cc. of boiling distilled water in a porcelain dish; keep the water at about 100° C. for five minutes, holding the cotton under the surface with the aid of a glass rod. Then press out with the assistance of the rod, and decant 100 cc. of the water, filtering it if not clear. Now add 50 cc. of cold distilled water to the Purified Cotton, thoroughly working it through the Cotton with the glass rod, for ten minutes, and again decant 50 cc. of the water. Twice again wash the Cotton with 50 cc. portions of cold distilled water, in the manner described, and evaporate to dryness the combined washings so obtained in a porcelain or platinum dish on a water bath. The residue, dried to constant weight at 100° C., does not exceed 0.025 Gm. (*water-soluble substances*).

N. F. Preparation—Gossypium Stypticum.

Uses—Purified cotton is used in funnels for straining, in percolators for controlling the flow of the percolate, and for many other purposes besides its main use in surgery.

GOSSYPIUM STYPTICUM. N. F. Styptic Cotton

[Gossyp. Stypt.]

	Metric	Alternative
Purified Cotton	**100 Gm.**	3 oz. av. 231 gr.
Solution of Ferric Chloride	**80 cc.**	3 fl. oz. 38 min.
Glycerin	**16 cc.**	295 min.
Water	**225 cc.**	10 fl. oz.

Mix the solution of ferric chloride, glycerin and water, immerse the purified cotton in this solution, and allow it to remain one hour. Then remove it, press it until it has been brought to a weight of 300 Gm. [12 oz. av.] and spread it out in thin layers, in a warm place protected from dust and light. When dry transfer it to well-closed glass containers.

Uses—It is used as a hemostatic, being applied to wounds.

Products Resulting from the Decomposition of Cellulose

Under this head will be included—1. The preparations made by decomposing cellulose or lignin by the action of acids or alkalies. 2. Those made by destructive distillation.

Pyroxylin is placed in the first class, primarily because of its importance in pharmacy, medicine, and the arts.

PYROXYLINUM. U. S. Pyroxylin

[Pyroxylin.—Soluble Guncotton]

Pyroxylin is a product obtained by the action of a mixture of nitric and sulphuric acids on cotton, and consists chiefly of cellulose tetranitrate $[C_{12}H_{16}O_6(NO_3)_4 = 504.22]$.

Preparation—The process official in the U. S. P. 1890 was as follows:

	Metric	Alternative
Purified Cotton	**100 Gm.**	½ oz. av.
Nitric Acid	**1400 cc.**	7 fl. oz.
Sulphuric Acid	**2200 cc.**	11 fl. oz.
Alcohol,		
Ether,		
Water, each, a sufficient quantity.		

Mix the acids gradually in a glass or porcelain vessel, and, when the temperature of the mixture has fallen to 32° C., add the purified cotton. Using a glass rod imbue the cotton thoroughly with the acids, and allow it to macerate, until a sample of it, taken out, thoroughly washed with a large quantity of water, and subsequently with alcohol, and pressed, is found to be soluble in a mixture

of 1 volume of alcohol and 3 volumes of ether. Then remove the cotton from the acids, transfer it to a larger vessel, and wash it, first, with cold water, until the washings cease to have an acid taste, and then with boiling water, until they cease to redden blue litmus paper. Finally, drain the Pyroxylin on filter paper, and dry it in small, detached pellets, by means of a water bath or steam bath at a temperature not exceeding 60° C.

Shönbein, in 1846, first pointed out the fact that nitric acid acts on cotton and produces a soluble compound. It was subsequently proved that this substance, pyroxylin, or guncotton, belongs to a series of closely related nitro-compounds in which the nitric acid radicle replaces the hydroxyl of the cellulose formula. This is usually indicated as taking the double formula for cellulose $C_{12}H_{20}O_{10}$ with the displacement of the HO, thus:

$$\underset{\text{nitric acid}}{6HNO_3} + \underset{\text{cellulose}}{C_{12}H_{20}O_{10}} = \underset{\text{cellulose hexanitrate}}{C_{12}H_{14}O_4(NO_3)_6} + \underset{\text{water}}{6H_2O}$$

$$\underset{\text{nitric acid}}{5HNO_3} + \underset{\text{cellulose}}{C_{12}H_{20}O_{10}} = \underset{\text{cellulose pentanitrate}}{C_{12}H_{15}O_5(NO_3)_5} + \underset{\text{water}}{5H_2O}$$

$$\underset{\text{nitric acid}}{4HNO_3} + \underset{\text{cellulose}}{C_{12}H_{20}O_{10}} = \underset{\text{cellulose tetranitrate}}{C_{12}H_{16}O_6(NO_3)_4} + \underset{\text{water}}{4H_2O}$$

$$\underset{\text{nitric acid}}{3HNO_3} + \underset{\text{cellulose}}{C_{12}H_{20}O_{10}} = \underset{\text{cellulose trinitrate}}{C_{12}H_{17}O_7(NO_3)_3} + \underset{\text{water}}{3H_2O}$$

$$\underset{\text{nitric acid}}{2HNO_3} + \underset{\text{cellulose}}{C_{12}H_{20}O_{10}} = \underset{\text{cellulose dinitrate}}{C_{12}H_{18}O_8(NO_3)_2} + \underset{\text{water}}{2H_2O}$$

Intermediate nitro-celluloses have also been prepared, Vieille having made at least eight different forms which suggested the possibility of double the cellulose formula shown above, but today it is thought that these differences are due to mechanical mixtures of the various nitro-celluloses.

The soluble pyroxylin used in preparing collodion is a varying mixture of the di-, tri-, tetra-, and pentanitrates, but is mainly tetranitrate. The hexanitrate is the true explosive guncotton, and is insoluble in ether, alcohol, acetone, or water.

Description and Physical Properties—A yellowish-white, matted mass of filaments, resembling raw cotton in appearance but harsh to the touch. It is exceedingly inflammable, burning, when unconfined, very rapidly and with a luminous flame. When kept in well-closed bottles and exposed to light, it is decomposed with the evolution of nitrous vapors, leaving a carbonaceous residue.

Tests for Identity—Pyroxylin is slowly but completely soluble in 25 parts of a mixture of three volumes of ether and one volume of alcohol. It is soluble in acetone and in glacial acetic acid and is precipitated from these solutions on the addition of water.

Tests for Purity—Saturate 0.5 Gm. of Pyroxylin with alcohol in a dish placed in cold water and ignite the Pyroxylin at the top. When combustion is complete and the dish heated to redness, not more than 0.3 per cent of ash remains.

Stir 1 Gm. of Pyroxylin with 20 cc. of distilled water for ten minutes and filter: the filtrate does not acquire an acid reaction. Evaporate 10 cc. of the filtrate from the preceding test to dryness on a water bath: not more than 0.0015 Gm. of residue remains (*soluble substances*).

Preserve in cartons, packed loosely, and protected from light and moisture.

Preparations—Collodium, Collodium Flexile.

U. S. P. and N. F. Preparations—Collodium, and, from Collodion, the several medicated Collodions are prepared (see pages 343 and 344).

Uses—Pyroxylin has been used very largely by photographers for producing the basis of the sensitized film upon which impressions are made. It is now replaced to a great extent by gelatin. The composition known as *celluloid*, which is employed so largely for useful and ornamental articles, is made from pyroxylin and camphor, heated together under pressure. The camphor, which acts as a plasticising medium has been replaced to some extent by other organic compounds, such as triphenyl phosphate and allied compounds.

Unofficial

ACIDUM OXALICUM. Oxalic Acid

$H_2C_2O_4.2H_2O = 126.06$

This acid was omitted from the alphabetical list of chemical substances in the U. S. Pharmacopœia; it is found, however, among the official reagents.

Preparation—Oxalic acid, also known as *dicarboxyl*, is dibasic, and is frequently found in plants in the form of crystals of calcium oxalate of distinctive forms. It may be made by acting on cellulose, sugar, or starch with nitric acid, with the aid of heat, and is prepared on a commercial scale by heating dried sawdust with a mixture of two molecules of caustic soda and one molecule of caustic potash. The mixture of caustic alkalies and sawdust is made in a thick paste and then heated for several hours to a temperature of about 240° C. The greenish-yellow mass is then washed with sodium carbonate, whereby the potassium is removed as carbonate, the less soluble sodium oxalate remaining. This is converted into calcium oxalate by milk of lime, and the calcium salt is then decomposed with sulphuric acid. The impure oxalic acid is finally purified by recrystallization.

It is also prepared on a large scale by heating a mixture of potassium formate with a little potassium oxalate and a slight excess of alkali. The oxalate so obtained is liberated by the addition of sulphuric acid.

It has also been produced directly from CO_2 and metallic sodium.

It occurs in small, colorless clino-rhombic crystals, which are odorless and have a very sour taste; it is slightly efflorescent in dry air, fusible at 98° C., and entirely volatile at a red heat.

The crystals should dissolve in ten parts of distilled water at 25° C. It is soluble in 4.5 parts of absolute alcohol, and in 2.5 parts of alcohol, and is almost insoluble in ether, chloroform, benzene, and petroleum benzin. It fuses in its water of hydration at 98° C., although continued exposure to a heat of 60° to 70° C., will render it perfectly anhydrous. Solutions of oxalic acid at 100° C. lose acid by sublimation and at 157° C. it sublimes rapidly. If the heat rises to 160° C. much loss of acid occurs. (See Reagents, Chapter XCII.)

It combines with salifiable bases, and forms salts called oxalates. The most important of these are the three *potassium salts—oxalate*, *binoxalate*, and *quadroxalate* (acid potassium oxalate plus free oxalic acid), *ammonium oxalate* (used as a test), and *calcium oxalate*. The binoxalate and quadroxalate, popularly called *salt of sorrel* or *essential salt of lemons*, are employed for removing iron stains from linen, and act by their excess of acid, which forms a soluble salt with the ferric oxide constituting the stain. The name "essential salts of lemon" is a particularly dangerous one as citric acid is also known by the same synonym. Oxalates should always bear a poison label when dispensed.

Oxalic acid in solution combines readily with calcium compounds forming an insoluble white precipitate consisting of calcium oxalate, which is insoluble in an excess of oxalic or acetic acid, but is dissolved by dilute hydrochloric acid.

Uses—This acid was used in the U. S. P. VIII as a reagent for establishing a standard for volumetric solutions, since a pure acid may be easily obtained and a definite quantity weighed. It is used in the test solutions and volumetric solutions of the U. S. Pharmacopœia. It is not, however, as frequently directed as in former Pharmacopœias, due to the tendency of the solution to crystallize at the delivery point of the burette, causing errors through the crystals falling into the solution which is being tested.

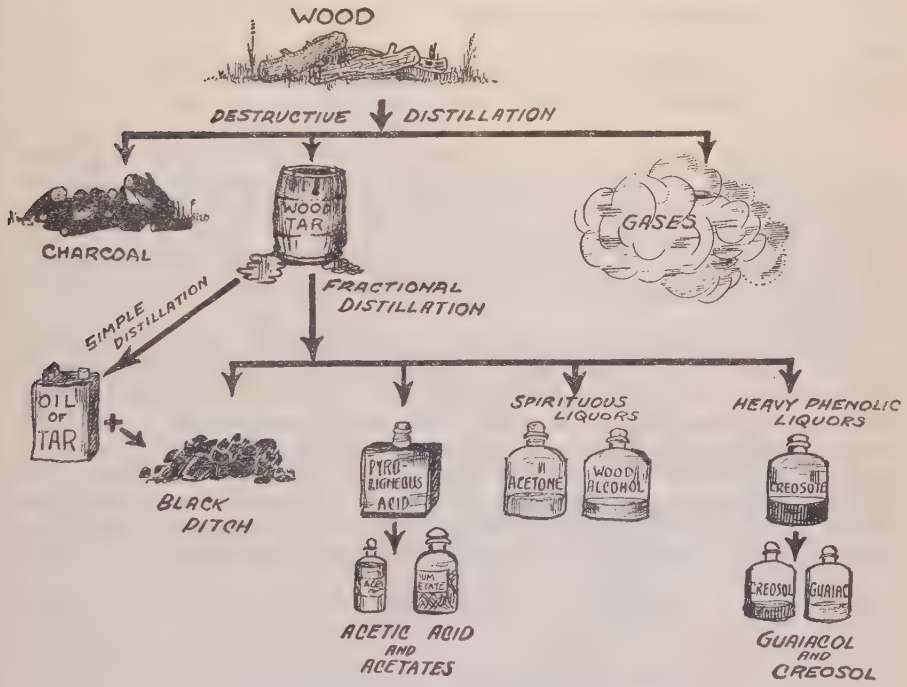
The best antidote to poisoning by oxalic acid is a paste made by mixing prepared chalk or powdered chalk with water or lime water; it must be

administered promptly and freely. Calcium chloride or any non-toxic salt of calcium may be used; magnesia has some antidotal effect although it is less valuable than lime.

Products Resulting from the Destructive Distillation of Cellulose and Lignin

When wood is distilled in a closed vessel, many products are obtained. These vary with the kind of wood used, the care used in the distillation, and the temperature at which the distillation is effected. When dry hard woods (oak, walnut, or beech) are distilled, about 25 per cent of charcoal is obtained; the

Fig. 434



Products from the destructive distillation of wood.

liquid portion amounts to about 53 per cent, while the remainder, 22 per cent, is represented by waste products, principally uncondensible gases, carbon dioxide, carbon monoxide, etc. The principal solid, liquid, and gaseous products are shown by Fig. 434, and by the following list:

Solids—Charcoal, inorganic salts, etc. **Liquids**—1. Aqueous liquid, containing *acetic, formic, butyric, crotonic, capronic,* and *propionic acids; acetone, methyl alcohol, furfurol, methylamine, pyrocatechin,* and some small quantities of *empyreumatic oils* and *resins.* 2. Tarry liquid, containing *toluol, xylol, cumol, methol, mesitylene, pseudocumol, phenol, cresol, guaiacol, creosol, phlorol, methylcreosol, naphthalene, paraffin, pyrene, chrysene, retene, mesit.* **Gases**—*Carbon dioxide, carbon monoxide, methane, acetylene, ethylene, propene,* and others. The most important products are *charcoal, tar, acetic acid, acetone, methyl alcohol,* and *creosote.* Of these, charcoal has been considered on page 589.

ACIDUM ACETICUM. U.S. Acetic Acid

[Acid. Acet.]

Acetic Acid is an aqueous solution containing not less than 36 per cent and not more than 37 per cent of $CH_3.COOH = (60.04)$.

Preparation—Acetic acid is an important product of the hard wood destructive distillation industry. It is obtained commercially by neutralizing the crude wood distillate called *pyroligneous acid* with milk of lime, decomposing the calcium acetate with sulphuric acid, and distilling off the liberated acetic acid. The reactions that take place in this separation are shown in the following equations:

$$\underset{\text{acetic acid(crude)}}{2CH_3COOH} + \underset{\substack{\text{calcium hydroxide}\\\text{(milk of lime)}}}{Ca(OH)_2} = \underset{\text{calcium acetate}}{(CH_3COO)_2Ca} + \underset{\text{water}}{2H_2O}$$

then

$$\underset{\text{calcium acetate}}{(CH_3COO)_2Ca} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{calcium sulphate}}{CaSO_4} + \underset{\text{acetic acid}}{2CH_3COOH}$$

The temperature used for distilling wood may be much less than that necessary to produce charcoal. The advantages of this process are that the production of the empyreumatic substances, which constitute the most objectionable impurities in the commercial acid, is largely curtailed, the process being at the same time more economical, as the residue of slightly darkened wood is more valuable than the completely charred carbon left by the ordinary process.

Acetic acid is also made by distilling *vinegar*, a liquid made by the oxidation of dilute alcoholic liquids, such as cider, wine, etc. In Germany acetic acid is made by mixing alcohol with water in the proportion of eight parts of the former to ninety-two parts of the latter, and then pouring it upon beech wood shavings which have been impregnated with cultures of *Mycoderma aceti*. As the alcoholic liquid trickles through it is oxidized by the action of the air, through the agency of the microörganisms. Aldehyde is an intermediate product. This " quick vinegar " process is now extensively used in the United States, being also employed for the acetification of "hard cider".

$$\underset{\text{alcohol}}{C_2H_6O} + \underset{\text{oxygen}}{O} = \underset{\text{aldehyde}}{C_2H_4O} + \underset{\text{water}}{H_2O}$$

$$\underset{\text{aldehyde}}{C_2H_4O} + \underset{\text{oxygen}}{O} = \underset{\text{acetic acid}}{C_2H_4O_2}$$

Various strengths of acetic acid are found in commerce—the official acid (36 to 37 per cent), which has the sp. gr. 1.045 at 25° C., stronger acids of 60 or 80 per cent strength, which may be used economically for making the weaker acid, and also the *No. 8 acid*, as it is called (30 per cent), which is still used; the latter has the sp. gr. 1.038 at 25° C. and is weaker than the official acid. It is termed " No. 8 " because it was formerly used in the proportion of one part in eight to make the ordinary diluted acetic acid, equivalent in strength to distilled vinegar.

Tests for Acetates

Acetates—When warmed with concentrated sulphuric acid, acetates evolve acetic acid. If acetic acid or an acetate is warmed with sulphuric acid and alcohol, the characteristic fragrant odor of ethyl acetate is evolved. With neutral solutions of acetates, ferric chloride T.S. produces a deep red color which is destroyed by the addition of mineral acids.

Description and Physical Properties—A clear, colorless liquid, having a strong, characteristic odor, and a sharply acid taste.

Acetic acid is miscible with water, alcohol, and glycerin.

Specific gravity: about 1.045 at 25° C.

Tests for Identity—Acetic Acid is strongly acid to litmus paper and responds to the reactions for acetates, page 800.

Tests for Purity—Evaporate 20 cc. of Acetic Acid on a water bath, and dry to constant weight at 100° C.: the weight of the residue does not exceed 0.002 Gm.

Mix 5 cc. of the Acid with 10 cc. of ammonia T.S., add 5 cc. of silver nitrate T.S., and boil the solution for one minute: the color of the solution is not changed (*formic or sulphurous acid*).

Dilute 4 cc. of the Acid in a glass-stoppered bottle with 20 cc. of distilled water, and add 0.5 cc. of tenth-normal potassium permanganate: the pink color is not changed to brown at once, and the liquid does not become entirely brown or free from a pink tint in less than one-half minute (*empyreumatic substances*).

Separate portions of 1 cc. each of Acetic Acid diluted with 10 volumes of distilled water show no turbidity on the addition of 5 drops of barium chloride T.S. (*sulphate*), and no opalescence with 5 drops of silver nitrate T.S. (*chloride*).

Acetic Acid diluted with 20 volumes of distilled water meets the requirements of the test for *heavy metals*, page 1519.

Assay—Proceed as directed under the assay for acids, page 1514, using about 6 cc. of the Acid, accurately weighed and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.06004 Gm. of $CH_3.COOH$.

This assay is explained on page 1453.

Preserve in glass-stoppered bottles.

U. S. P. Preparations—Acidum Aceticum Dilutum; Extractum Nucis Vomicæ.

N. F. Preparations—Acetum Aromaticum; Linimentum Terebinthinæ Aceticum; Liquor Alumini Subacetatis.

Uses—Acetic acid is used in pharmacy as a solvent and menstruum, and for making the diluted acetic acid. The crude acetic acid called pyroligneous acid is sometimes put up under the name of "liquid smoke" and sold for the purpose of preserving meat, fish, etc., which are dipped therein and then dried, instead of subjecting them to the customary smoking process. This use of pyroligneous acid is prohibited by most food laws.

ACIDUM ACETICUM DILUTUM. U.S. Diluted Acetic Acid

[Acid. Acet. Dil.]

Diluted Acetic Acid is an aqueous solution containing not less than 5.7 per cent and not more than 6.3 per cent of $CH_3.COOH$ (60.04).

	Metric	Alternative
Acetic Acid	**165 Gm.**	5 fl. oz. 35 min.
Distilled Water	**835 Gm.**	26 fl. oz. 445 min.
To make	**1000 Gm.**	2 pints

Mix them.

Description and Physical Properties—A clear, colorless liquid, having a characteristic odor.

Diluted Acetic Acid is miscible with water and with alcohol.

Specific gravity: about 1.008 at 25° C.

Tests for Identity and Purity—Diluted Acetic Acid is acid to litmus paper and responds to the reactions for acetates, page 800.

It conforms to the tests for purity under *Acidum Aceticum*, allowance being made for the difference in strength.

Assay—Proceed as directed under the assay for acids, page 1514, using about 25 cc. of the Acid, accurately weighed, and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.06004 Gm. of $CH_3.COOH$.

This assay is explained on page 1453.

Preserve in glass-stoppered bottles.

U. S. P. Preparations—Acetum Scillæ; Liquor Ammonii Acetatis; Liquor Ferri et Ammonii Acetatis.

N. F. Preparations—Mistura Adstringens; Syrupus Allii.

Uses—Diluted acetic acid is superior to vinegar as a menstruum, and is used officially because of its greater purity, more uniform strength, and freedom from color. It is of service as an astringent, as in sunburn, and as a styptic. The dose is thirty minims (2 cc.).

ACIDUM ACETICUM GLACIALE. U.S. Glacial Acetic Acid

[Acid. Acet. Glac.]

Glacial Acetic Acid contains not less than 99 per cent of $CH_3.COOH$(60.04).

Preparation—This acid (which is termed "glacial" because of its solid glassy appearance when congealed) is made by fusing carefully fifty-four parts of pure crystallized sodium acetate; the residue is coarsely powdered, placed in a retort, mixed with forty parts of pure concentrated sulphuric acid, and distilled; the distillate is glacial acetic acid.

$$\underset{\text{sodium acetate}}{NaC_2H_3O_2} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{H_2SO_4} = \underset{\substack{\text{glacial acetic}\\\text{acid}}}{HC_2H_3O_2} + \underset{\substack{\text{acid sodium}\\\text{sulphate}}}{NaHSO_4}$$

The specific gravity of glacial acetic acid (100 per cent) is 1.0471 at 25° C. and the specific gravity of 39 per cent acetic acid is nearly the same, 1.0474, while 79, 80, 77, and 76 per cent acids have exactly the same density. It will thus be seen that specific gravity cannot be relied upon as a criterion for strength. The glacial acid may, however, be distinguished from the 39 per cent acid by adding 10 per cent of water, when, if the density increases, the specimen is the stronger acid. (See Acetic Acid table, U. S. P. X.)

Description and Physical Properties—A clear, colorless liquid, having a strong, characteristic odor, and a very pungent, acid taste.

Glacial Acetic Acid is miscible with water, alcohol, and glycerin.

Specific gravity: from 1.047 to 1.050 at 25° C.

Tests for Identity and Purity—Congealing point: not below 14.5° C. It boils between 117° and 118° C.

Glacial Acetic Acid responds to the reactions for acetates, page 800.

It conforms to the tests for purity under *Acidum Aceticum* when diluted to that strength, except in the following respects:

The pink color produced by the addition of 0.1 cc. of tenth-normal potassium permanganate to 2 cc. of Glacial Acetic Acid, which has been diluted with 10 cc. of distilled water and is contained in a glass-stoppered bottle, is not changed to brown within two hours (*readily oxidizable impurities*).

Evaporate 20 cc. of Glacial Acetic Acid to dryness on a water bath, and dry to constant weight at 100° C.: the weight of the residue does not exceed 0.002 Gm.

Assay—Proceed as directed under the assay for acids, page 1514, using about 2.5 Gm. of the Acid, accurately weighed, and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.06004 Gm. of $CH_3.COOH$.

This assay is explained on page 1453.

Preserve in glass stoppered bottles.

U. S. P. Preparations—Ceratum Cantharidis; Tinctura Cantharidis.

Uses—Glacial acetic acid is a solvent for fixed and volatile oils. Medicinally, it is a caustic and vesicant when applied externally. It is often sold under various disguises as a corn solvent.

ACIDUM TRICHLORACETICUM. U.S. Trichloracetic Acid

[Acid. Trichloracet.]

Trichloracetic Acid, dried to constant weight over sulphuric acid, contains not less than 99 per cent of $CCl_3.COOH$ (163.40).

Preparation—This acid, discovered by Dumas in 1838, may be made by oxidizing 165.5 Gm. of chloral hydrate, previously fused at 58° C. with 63 Gm. of fuming nitric acid, and placing the mixture aside for an hour or until the red fumes have disappeared; the liquid is then distilled, and the portion coming over above 190° C. is trichloracetic acid, which is then crystallized.

Description and Physical Properties—Colorless, deliquescent crystals having a slight, characteristic odor.

One Gm. of Trichloracetic Acid is soluble in about 0.1 cc. of water at 25° C. It is very soluble in alcohol and in ether.

Tests for Identity—Trichloracetic Acid heated with a solution of an alkali hydroxide is decomposed with the formation of alkali carbonate and chloroform, the latter being recognizable by the odor of phenylisocyanide (a poisonous substance), when a few drops of a saturated, aqueous solution of aniline are added to the heated mixture.

Tests for Purity—Ash: not more than 0.05 per cent.

Dissolve about 0.5 Gm. of ferrous sulphate in 5 cc. of an aqueous solution of Trichloracetic Acid (1 in 20) and superimpose it upon 5 cc. of sulphuric acid: no brownish-red color develops at the zone of contact (*nitric acid*).

One Gm. of Trichloracetic Acid shows no more *chloride* than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid, page 1520.

Assay—Proceed as directed under the assay for acids, page 1514, using about 4 Gm. of the Acid, previously dried to constant weight over sulphuric acid, and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.1634 Gm. of CCl_3COOH.

Each Gm. of Trichloracetic Acid, previously dried to constant weight over sulphuric acid, corresponds to not less than 6.06 cc. and to not more than 6.12 cc. of normal sodium hydroxide.

This assay is explained on page 1453.

Preserve in well-stoppered bottles, in a cool place, protected from light.

Uses—This acid was first introduced into the U. S. P. VIII; it is used as a caustic in solution or in crystals.

ACETONUM. U. S. Acetone

[Aceton.—Dimethyl-ketone]

Acetone contains not less than 99 per cent of $CH_3.CO.CH_3$ (58.06).

Preparation—This liquid may be made by the distillation of dry calcium acetate, obtained by neutralizing crude wood spirit with milk of lime, at 290° C. The reaction involved is expressed as follows:

$$\underset{\text{calcium acetate}}{CH_3COO\diagdown \atop CH_3COO\diagup Ca} = \underset{\text{calcium carbonate}}{CaCO_3} + \underset{\text{acetone}}{\begin{matrix} CH_3 \\ | \\ CO \\ | \\ CH_3 \end{matrix}}$$

It is also found in crude wood spirit in varying proportions but it is separated, with difficulty, from methyl alcohol, which constitutes the principal bulk in the wood spirit, because methyl alcohol boils at 55° C. and acetone at about 56.5° C., the difference being too slight to use fractional distillation with success.

Description and Physical Properties—A transparent, colorless, mobile and volatile liquid, having a characteristic odor. It is inflammable.

Acetone is miscible without cloudiness with water, alcohol, ether, chloroform, and most volatile oils.

Tests for Identity—Specific gravity: about 0.790 at 25° C.

It boils between 56° and 58° C., but volatilizes even at low temperatures.

Add 1 cc. of sodium hydroxide T.S. to 1 cc. of an aqueous dilution of Acetone (1 in 200), warm the mixture, and add a few cc. of iodine T.S.: a yellow precipitate of iodoform is formed at once.

Mix 1 cc. of the same Acetone dilution with five drops of sodium nitroprusside T.S. and 2 cc. of sodium hydroxide T.S. and add a slight excess of acetic acid: a deep red liquid is produced which develops a violet tint when diluted with several volumes of water.

Tests for Purity—Acetone diluted with an equal volume of distilled water does not affect the color of blue or red litmus paper previously moistened with water.

Evaporate 50 cc. of Acetone in a dish on a water bath, and dry to constant weight at 100° C.: the weight of the residue does not exceed 0.002 Gm.

Mix 20 cc. of Acetone with 0.1 cc. of tenth-normal potassium permanganate in a clean glass-stoppered bottle: the pink tint produced does not wholly disappear in less than fifteen minutes (*empyreumatic substances*).

Assay—Determine the exact weight of a glass-stoppered weighing bottle containing 15 cc. of distilled water, add about 1 cc. of Acetone, and again weigh accurately. Transfer the contents of the bottle to a 1000 cc. graduated flask, rinse the weighing bottle with several portions of distilled water, and add the rinsings to the flask. Fill to the mark with distilled water, and mix thoroughly. Place 25 cc. of normal sodium hydroxide in a 250 cc. glass-stoppered flask, add exactly 25 cc. of the Acetone solution and 35 cc. of tenth-normal iodine, with constant agitation of the flask, and

allow the mixture to stand for fifteen minutes. Add 26 cc. of normal hydrochloric acid, and at once titrate the residual iodine with tenth-normal sodium thiosulphate, adding starch T.S. as indicator when the liquid is nearly decolorized. Conduct a blank test with the same quantities of the reagents, and subtract the quantity of tenth-normal iodine consumed in the blank test from that consumed in the assay. Each cc. of the difference, which represents the iodine consumed by the reaction with the Acetone, corresponds to 0.0009677 Gm. of $CH_3.CO.CH_3$.

This assay is explained on page 1469.

Preserve in well-closed containers, in a cool place, remote from fire.

Uses—Acetone was formerly used as the menstruum in the preparation of oleoresins but is now replaced by ether. It is used as a solvent for dissolving fatty bodies, resins, pyroxylin, etc. It is at present largely used in the manufacture of chloroform.

PIX PINI. U.S. Pine Tar

[**Pix Pin.**—Pix Liquida U.S.P. IX]

A product obtained by the destructive distillation of the wood of *Pinus palustris* Miller, or of other species of *Pinus* (Fam. *Pinaceæ*).

Preparation—Tar is usually obtained as a by-product in the manufacture of charcoal or acetic acid (see page 800). It is a complex mixture of phenolic bodies for the most part insoluble in water. Among these are *creosol*, *phlorol*, *guaiacol*, *pyrocatechol*, *cœrulignol* and *pyrogallol* esters. Traces of *phenol* and *cresols* are also present as well as hydrocarbons of the paraffin and benzene series.

Description and Physical Properties—A very viscid, blackish-brown, non-crystalline liquid. It is translucent in thin layers, becoming granular and opaque with age. It has an empyreumatic, terebinthinate odor and a sharp, empyreumatic taste.

Pine Tar is heavier than water and is slightly soluble in it, the solution being pale yellowish to yellowish-brown and acid to litmus paper.

Pine Tar is miscible with alcohol, ether, chloroform, glacial acetic acid, and fixed and volatile oils.

Tests for Identity and Purity—Shake about 1 cc. of Pine Tar with 10 cc. of water for ten minutes, filter, and add 1 drop of ferric chloride T.S. to the filtrate. A green color is produced, rapidly changing to brown.

Ash: not more than 0.25 per cent.

Preserve in well-closed containers.

U. S. P. Preparation—Unguentum Picis Pini.
N. F. Preparation—Glyceritum Picis Pini.

History—An aqueous extract of tar was claimed by George Berkeley, Bishop of Cloyne, in the early part of the eighteenth century to be a panacea for all human ills and he wrote a book upon "*Tar Water*" which makes very interesting reading as an example of misbelief and credulity.

Uses—The volatile products of tar are expectorant, and tar inhalations are often used. The dose of tar is 8 grains (0.5 Gm.). Externally, tar is stimulating and antiseptic and is used in skin diseases.

Unofficial Preparation

LIQUOR PICIS ALKALINUS. N.F.IV. Alkaline Solution of Tar

Dissolve 125 Gm. of potassium hydroxide in 625 cc. of water, add 250 Gm. of pine tar, and agitate until solution is effected. Allow it to stand twenty-four hours, then strain the solution through purified cotton, and pass sufficient water through the strainer to make the product measure 1000 cc.

Uses—Used externally as an antiseptic in dermatologic practice.

OLEUM PICIS RECTIFICATUM. U.S. Rectified Oil of Tar

[Ol. Pic. Rect.—Oleum Picis Liquidæ Rectificatum U.S.P. IX]

The volatile oil from pine tar rectified by steam distillation.

Description and Physical Properties—A thin liquid, having a dark reddish-brown color, and a strong, empyreumatic odor and taste.

Tests for Identity and Purity—The Oil is soluble in all proportions in alcohol.

Specific gravity: 0.960 to 0.990 at 25° C.

An alcoholic solution of the Oil is acid to moistened blue litmus paper.

U.S.P. Preparation—Syrupus Picis Pini.

N.F. Preparation—Unguentum Picis Compositum.

Uses—The constituents of oil of tar are complex and numerous; the residue left after the distillation of tar is *black pitch*. The oil is preferred to tar for most medicinal uses, because the insoluble and inert substances have been separated. The dose is three minims (0.2 cc.).

OLEUM CADINUM. U.S. Oil of Cade

[Ol. Cadin.—Cade Oil, Oil of Juniper Tar, Oleum Juniperi Empyreumaticum]

The empyreumatic volatile oil obtained from the wood of *Juniperus Oxycedrus* Linné (Fam. *Pinaceæ*).

Description and Physical Properties—A dark brown, clear, thick liquid, having a tarry odor, and a warm, faintly aromatic, bitter taste.

The Oil is very slightly soluble in water, but imparts to it an acid reaction shown by moistened blue litmus paper. It is only partially soluble in alcohol and in petroleum benzin, but completely soluble in three volumes of ether and soluble in all proportions in amyl alcohol, chloroform, glacial acetic acid, and in oil of turpentine.

Tests for Identity and Purity—Specific gravity: 0.980 to 1.055 at 25° C.

Shake 1 part of Oil of Cade with 20 parts of warm distilled water, and filter: separate portions of 5 cc. each of the aqueous filtrate give a red coloration with three drops of ferric chloride solution (1 in 1000), blacken silver ammonium nitrate T.S. in the cold, and give a red precipitate with alkaline cupric tartrate T.S. on heating.

Agitate 1 cc. of Oil of Cade with 15 cc. of purified petroleum benzin, filter the solution, add an equal volume of copper acetate solution (1 in 100), shake the mixture, and allow it to separate. Decant the benzin layer into a test tube, and add to it an equal volume of ether: no intensely green coloration is produced, nor does the liquid become more than light yellow to brown (*rosin or rosin oils*).

N.F. Preparations—Linimentum Saponis Mollis Compositum; Petroxolinum Cadini; Petroxolinum Sulphuratum Compositum; Unguentum Sulphuris Compositum.

Uses—It is used as a local application in skin diseases.

OLEUM BETULÆ EMPYREUMATICUM RECTIFICATUM. N.F. Rectified Oil of Birch Tar

[Ol. Bet. Empyr. Rect.—Rectified Pyroligneous Oil of Birch, Oleum Rusci Rectificatum, Russian Leather Oil]

The pyroligneous oil obtained by the dry distillation of the bark and wood of *Betula alba* Linné (Fam. *Betulaceæ*), rectified by steam distillation.

It contains guaiacol, cresol, and pyrocatechol.

Official Description—A limpid, dark brown liquid.

Odor and Taste—A penetrating, empyreumatic odor resembling that of Russia leather.

Solubility—It yields clear solutions with three volumes of dehydrated alcohol, and with ether chloroform, glacial acetic acid, amyl alcohol, oil of turpentine, benzene, or carbon disulphide. When mixed with three volumes of alcohol or purified petroleum benzin, the solution is not more than slightly turbid, but a decided turbidity is produced when mixed with the same volume of methanol.

Specific gravity: 0.886 to 0.950 at 25° C.

Tests for Identity and Purity—Warm 2 cc. of the Oil with 10 cc. of distilled water, agitate and allow the mixture to cool; separate and filter the aqueous liquid. The filtrate is colorless, has a strong, empyreumatic odor and an acid reaction. Add two drops of potassium dichromate T.S.

to 4 cc. of the aqueous filtrate: a bright yellow solution is produced which soon becomes darker and turbid. Add one drop of dilute ferric chloride solution (1 in 100) to 4 cc. of the filtrate: it produces a green coloration which changes to brown and becomes turbid (distinction from *oil of cade*).

N.F. Preparation—Unguentum Resorcinolis Compositum.

Uses—It is similar to oil of cade, being used externally in the form of an ointment for eczema and other skin affections.

CREOSOTUM. U.S. Creosote

[**Creosot.**—CREASOTE]

A mixture of phenols, principally guaiacol [$C_6H_4(OH)(OCH_3)$ 1:2 = 124.10] and creosol [$C_6H_3(CH_3)(OH)(OCH_3)$ 1:2:3 = 138.12] obtained from wood tar.

Preparation—This is a product of the distillation of wood tar, consisting mainly of the following phenols: *guaiacol*, or *oxycresol*, $C_7H_8O_2$, boiling at 200° C.; *creosol*, $C_8H_{10}O_2$, boiling at 217° C.; *methyl-creosol*, $C_9H_{12}O_2$, boiling at 214° C. to 218° C.; *phlorol*, $C_8H_{10}O$, boiling at 219° C.

Wood tar, preferably that from beechwood, is distilled until about one-half passes over and the dense vapors of higher boiling constituents appear. The distillate separates into three strata, the lower of heavy, the upper of lighter oily liquid, with an aqueous acid layer between. The oil contains *eupion*, which is a liquid consisting chiefly of pentane. The heavy oil is then shaken with a concentrated solution of sodium carbonate, to neutralize the acetic acid, the separated oily liquid is again distilled, and only the portion heavier than water collected. The distillate is now treated with potassium hydroxide, in which the creosote dissolves, the hydrocarbons separating. Sulphuric acid is now added to neutralize the potassium hydroxide and the separated creosote is well washed with water and redistilled, the portion coming over between 200° and 220° C. being collected. Formerly much of the liquid sold for and labeled "creosote" in the market was impure phenol (carbolic acid), or so called "coal-tar creosote". In view of the extensive use of wood creosote in large doses internally in phthisis, the liability of administering a large dose of phenol and causing death through this substitution is very great. Phenol may be distinguished from true wood creosote by the tests given below. The odor of each is distinctive and characteristic.

Description and Physical Properties—An almost colorless or yellowish, highly refractive, oily liquid, having a penetrating, smoky odor, and a burning, caustic taste. It does not readily become brown on exposure to light. Creosote is inflammable, burning with a luminous, smoky flame.

Creosote is slightly soluble in water, but is miscible with alcohol, ether, and with fixed or volatile oils.

Tests for Identity—Add 1 drop of ferric chloride T.S. to 10 cc. of a saturated aqueous solution of Creosote: a violet-blue color, which is very transient, develops. The liquid becomes cloudy almost instantly, the color changing rapidly from grayish-green to muddy brown, with the formation, finally, of a brown precipitate.

Tests for Purity—Specific gravity: not below 1.076 at 25° C.

It begins to distil at about 200° C. and not less than 90 per cent, by volume, distils between 200° and 220° C. when determined by Method II, page 121.

Creosote is neutral or faintly acid to moistened litmus paper.

Mix equal volumes of Creosote and collodion in a dry test tube: no permanent coagulum is produced (*phenol* and so-called "*coal-tar creosote*").

Mix 4 cc. of Creosote and 4 cc. of glycerin, add 1 cc. of water, shake the mixture gently, and allow it to stand: a creosote layer separates equal to or greater in volume than the Creosote taken (so-called "*coal-tar creosote*").

A 2 cc. portion of Creosote requires not less than 10 cc. and not more than 18 cc. of normal sodium hydroxide to produce a clear liquid. This liquid remains unclouded on diluting with 50 cc. of distilled water (*hydrocarbons and bases*).

Shake gently 1 cc. of Creosote with 2 cc. of petroleum benzin and 2 cc. of freshly prepared barium hydroxide T.S. until a uniform mixture results: upon complete separation three distinct layers are visible, the upper layer being neither blue nor muddy (*cærulignol*).

Preserve in tightly-stoppered, dark amber-colored bottles.

N. F. Preparations—Elixir Terpini Hydratis et Creosoti Compositum; Mulla Creosoti Salicylata.

Uses—Creosote is used internally as an expectorant in bronchitis and phthisis and as a gastro-intestinal antiseptic. It is occasionally employed externally for its disinfectant action. It is applied upon cotton to exposed nerve tissue in teeth, when it acts as a local anesthetic. It is also hemostatic when applied to bleeding surfaces. When taken internally, undiluted, and in large doses, it is a powerful poison. The administration of mucilaginous drinks, and the prompt evacuation of the stomach by the stomach pump, would be the best treatment, no antidote to poisoning by creosote being known. Dose: four minims (0.25 cc.).

CREOSOTI CARBONAS. U. S. Creosote Carbonate

[Creosot. Carb.]

Creosote Carbonate is a mixture of the carbonates of various constituents of creosote, chiefly guaiacol and creosol.

Preparation—It is prepared by passing a current of carbonyl chloride, or phosgene, into a solution of creosote in sodium hydroxide and washing the product with weak soda solution and water.

The local action and toxicity of creosote is minimized by masking the active OH group, through the replacement of the H group by an acid radicle as in this official product. These compounds are insoluble in water and inactive but are saponified in the intestines and gradually liberate their active constituents.

Description and Physical Properties—A clear, colorless or yellowish, viscid liquid. It is odorless and tasteless, or has a slight odor and taste of creosote. On prolonged exposure to a low temperature, crystals of guaiacol carbonate may separate, which redissolve on warming.

Creosote Carbonate is insoluble in water, but is freely soluble in alcohol. It is soluble in petroleum benzin and in fixed oils, and is miscible with chloroform and with benzene.

Tests for Identity—Heat about 0.5 cc. of Creosote Carbonate for a few minutes with 10 cc. of alcoholic potassium hydroxide T.S. and cool the mixture: a crystalline precipitate forms, which effervesces with acids.

Tests for Purity—Specific gravity: not below 1.145 at 25° C.

Ash: not more than 0.1 per cent.

An alcoholic solution of Creosote Carbonate (1 in 5) is neutral to moistened litmus paper, and acquires only a yellow color on the addition of a drop of ferric chloride T.S. (*free creosote*).

Heat 25 cc. of Creosote Carbonate in a water bath for half an hour with a solution of 15 Gm. of potassium hydroxide in 100 cc. of alcohol, add about 50 cc. of water, and evaporate the alcohol. Treat the residue with an excess of hydrochloric acid, and allow the liquid to separate into two layers. Separate the creosote layer, wash it by shaking at first with 15 cc. of a 20 per cent aqueous solution of sodium chloride, then with 10 cc. of water, and distil: eighty-five per cent of the creosote thus obtained, allowance being made for adhering moisture, distils between 200° and 220° C. when determined by Method II, page 121. The distillate, after the separation of adhering water, does not respond to the test for *hydrocarbons and "coal-tar creosote"* under *Creosotum.*

Uses—Creosote Carbonate (also sold under the name *creosotal*) is claimed to be non-toxic and devoid of irritating properties. It is employed as an expectorant in doses of five to fifteen grains (0.3 to 1 Gm.).

GUAIACOL. U. S. Guaiacol

A liquid consisting principally of $C_6H_4(OH)(OCH_3)$ 1:2 (124.10), usually obtained from wood creosote, or a solid, consisting almost entirely of $C_6H_4(OH)(OCH_3)$ 1:2, usually prepared synthetically.

Preparation—It may be obtained from wood creosote by fractional distillation and purification or be produced synthetically by heating a mixture of equal molecules of pyrocatechin, potassium hydroxide, and potassium methyl-

sulphate, in a closed vessel at a temperature of 170° to 180° C., resulting in the following reaction:

$$\underset{\text{pyrocatechin}}{C_6H_4(OH)_2} + \underset{\text{potassium hydroxide}}{KOH} + \underset{\text{potassium methylsulphate}}{KCH_3SO_4} = \underset{\text{guaiacol}}{C_6H_4.OH.OCH_3} + \underset{\text{potassium sulphate}}{K_2SO_4} + \underset{\text{water}}{H_2O}$$

The resulting guaiacol is removed by solution in alcohol or benzin and purified by recrystallizing.

Description and Physical Properties—Liquid Guaiacol is colorless or yellowish; solid Guaiacol is crystalline and is colorless or yellowish. Guaiacol becomes darker on exposure to light. When liquefied, the solid form may remain liquid for a long time even at a low temperature. Guaiacol has an agreeable, aromatic odor.

One Gm. of Guaiacol is soluble in from 60 to 70 cc. of water and in 1 cc. of glycerin, at 25° C., but separates from the glycerin on the addition of water. It is miscible with alcohol, chloroform, ether, and with glacial acetic acid.

Tests for Identity—Solid Guaiacol melts at about 28° C.

The addition of a drop of ferric chloride T.S. to 10 cc. of an alcoholic solution of Guaiacol (1 in 100) immediately produces a blue color, changing to emerald-green, and finally becoming yellowish.

Tests for Purity—Specific gravity: liquid Guaiacol, not below 1.112 at 25° C., melted solid Guaiacol, about 1.132 at 25° C.

Not less than 85 per cent of liquid Guaiacol distils between 200° and 210° C. when determined by Method II, page 121. Solid Guaiacol boils between 204° and 206° C.

Ash: not more than 0.1 per cent.

Shake 2 cc. of liquefied Guaiacol with 4 cc. of purified petroleum benzin: the mixture separates into two distinct, clear layers on standing. Permanent turbidity, or failure to separate into layers indicates the presence of impurities.

One cc. of liquefied Guaiacol dissolves in 2 cc. of 15 per cent potassium hydroxide solution when heated for one minute in boiling water; on cooling, the solution congeals to a nearly white mass. Much coloration or failure to congeal indicates the presence of impurities. The mass thus obtained forms a clear solution with 25 cc. of distilled water (*hydrocarbons*).

Preserve in well-closed containers, protected from light.

N. F. Preparation—Petroxolinum Guaiacolis.

Uses—Guaiacol is employed internally as an expectorant in bronchitis and in tuberculosis. It is occasionally used by endermic application in fevers. Dose: five to ten minims (0.3 to 0.6 cc.).

GUAIACOLIS CARBONAS. U.S. Guaiacol Carbonate
[Guaiacol. Carb.]

The guaiacol ester $[(C_6H_4(OCH_3)O)_2.CO = 274.19]$ of carbonic acid.

Preparation—It may be prepared by slowly passing carbonyl chloride into guaiacol, in sodium hydroxide solution, washing the resulting precipitate and crystallizing it from alcohol. The reaction is expressed by the following equation:

$$\underset{\text{guaiacol}}{C_6H_4\begin{cases}OCH_3\\OH\end{cases}C_6H_4\begin{cases}OH\\OCH_3\end{cases}} + \underset{\text{carbonyl chloride}}{Cl_2CO} = \underset{\text{guaiacol carbonate}}{C_6H_4\begin{cases}OCH_3\\O\end{cases}CO\begin{cases}O\\C_6H_4\end{cases}\begin{matrix}\\OCH_3\end{matrix}} + \underset{\text{hydrochloric acid}}{2HCl}$$

Description and Physical Properties—Small, colorless crystals, or a white, crystalline powder. It is odorless and tasteless, or has a slight, aromatic odor and taste.

Guaiacol Carbonate is insoluble in water. One Gm. is soluble in 60 cc. of alcohol, 1 cc. of chloroform, and in 18 cc. of ether, at 25° C. It is freely soluble in boiling alcohol and benzene, and is slightly soluble in glycerin and in fixed oils.

Tests for Identity—Guaiacol Carbonate melts between 85° and 88° C.

Heat about 0.5 Gm. of Guaiacol Carbonate for a few minutes with 10 cc. of alcoholic potassium hydroxide T.S., cool, and decant the liquid from the precipitate: the addition of an acid to the precipitate produces effervescence. Evaporate the alcohol from the decanted liquid, strongly acidulate the residue with diluted sulphuric acid, and shake with chloroform: the separated chloroform layer upon evaporation leaves a residue which responds to the ferric chloride test for identity under *Guaiacol*.

Tests for Purity—Ash: not more than 0.1 per cent.

A saturated alcoholic solution of Guaiacol Carbonate is neutral to litmus paper, previously moistened with distilled water, and yields no bluish-green color on the addition of ferric chloride T.S. (*free guaiacol*).

Dissolve 0.1 Gm. of Guaiacol Carbonate in 2 cc. of sulphuric acid: the solution is not darker than faint yellow (*readily carbonizable substances*).

Uses—Guaiacol Carbonate, known also as *duotal*, is given as an expectorant in doses of eight to fifteen grains (0.5 to 1 Gm.).

Unofficial Creosote and Guaiacol Compounds

Calcreose, N. N. R.—Calcium Creosotate—A mixture containing in loose chemical combination approximately equal weights of creosote and lime.

A dark brown powder, having an empyreumatic odor and a sharp phenolic taste. It is partially soluble in water; the alkaline solution containing calcium compounds of the phenolic bodies of creosote, while the insoluble portion consists largely of calcium hydroxide and calcium carbonate.

Actions and Uses—Calcreose, when administered internally, is claimed to have the same actions and uses as creosote. It is claimed that calcreose does not readily produce gastric distress, nausea and vomiting. Dose: 4 to 15 grains (0.25 to 1 Gm.).

Manufactured by The Maltbie Chemical Company, Newark, N. J.

Guaiacol Benzoate, N. N. R—Guaiacolis Benzoas—Benzosol. $C_6H_5COO.C_6H_4.OCH_3$. The benzoic acid ester of guaiacol.

In minute colorless crystals; odorless or having a faint, aromatic odor; tasteless or nearly so. Guaiacol benzoate is almost insoluble in water; soluble in ether and in chloroform; also soluble in hot alcohol.

Actions and Uses—Guaiacol benzoate is decomposed slowly in the intestinal tract into guaiacol and benzoic acid, which exert their usual actions. The liberated constituents are absorbed and exereted in the urine. It is claimed to be non-irritating. Dose: 3 to 10 grains (0.2 to 0.6 Gm.) in capsules, pills or as an emulsion.

Distributed by the H. A. Metz Laboratories, New York, and the Seydel Chemical Company, Jersey City, N. J.

With sulphuric acid guaiacol benzoate forms a permanent yellow coloration. Ferric chloride produces in the guaiacol benzoate-sulphuric acid mixture a violet color, changing to green and blue, and on the further addition of nitric acid, to orange and green, or of potassium nitrite to green, violet and yellow.

On heating with alcoholic potassium hydroxide, guaiacol benzoate is saponified and the odor of guaiacol is developed.

Guaiacol benzoate is incompatible with the alkalies, which split it into guaiacol and benzoic acid.

Incinerate about 1 Gm. of guaiacol benzoate, accurately weighed: the ash does not exceed 0.1 per cent.

Proposote, N. N. R—Creosote Phenylpropionate—A condensation product of creosote and phenylpropionic acid. Proposote contains the equivalent of 50 per cent of creosote.

An amber-colored oily liquid, having a characteristic odor, resembling creosote and a slightly bitter taste. It is insoluble in water, soluble in alcohol, ether, and fatty oils. The boiling point of proposote is above 360° C.; its specific gravity at 25° C. is 1.10.

Actions and Uses—Proposote is not decomposed by the gastric fluids and passes the stomach practically unabsorbed. It is decomposed in the intestines and the components are chiefly eliminated through the kidneys; but it is claimed that a part of the liberated creosote is eliminated through the respiratory tract. Claimed to be of value in bronchitis and in coughs due to bronchial infection. Dose: for adults 10 minims (0.6 cc.) in capsules.

Manufactured by Parke, Davis and Company, Detroit.

Thiocol, N. N. R.—Potassium Guaiacol-Sulphonate—$C_6H_3(OH)(OCH_3)(SO_3K)$, 1:2:6—The potassium salt of orthoguaiacol sulphonic acid, $C_6H_3(OH)(OCH_3)(SO_3H)$ 1:2:6.

A colorless, crystalline powder, neutral or faintly alkaline, odorless, and having a faintly bitter taste; soluble in water, slightly soluble in ordinary alcohol, but insoluble in absolute alcohol and in ether or oils.

Actions and Uses—Thiocol-Roche acts as a sedative expectorant. It has the advantage over guaiacol in that it is comparatively tasteless, does not disturb digestion and is non-toxic.

Claimed to be useful in the treatment of diseases of the respiratory tract, incipient tuberculosis and certain diarrheas. Dose: 5 to 20 grains (0.3 to 1.3 Gm.) in solution or tablets.

Manufactured by Hoffmann-La Roche Chemical Works, New York.

Unofficial Product of the Destructive Distillation of Cellulose

Methanol, CH_3OH
Methyl Alcohol
Methylic Alcohol
Wood Naphtha
Wood Alcohol
Pyroxylic Spirit
Columbian Spirit
Colonial Spirit

It occurs among the products of the dry distillation of wood. The watery liquid is separated from the tar and distilled; then the first portion of the distillate is rectified over slaked lime, so as to remove acid, etc., and the product treated with sulphuric acid to remove tar and neutralize ammonia and methylamine, and, lastly, redistilled.

Immense quantities of methanol are now being made in Germany by interaction between water gas and steam, under the influence of a catalyst said to be zinc oxide. The old method of chopping the hard wood, distilling it, and refining the product is much more costly and cannot compete with methanol prepared by this synthetic process in which water and coke are the raw materials. It is a colorless, limpid liquid, of a peculiar odor, resembling alcohol and acetic ether, and of a warm taste. Its specific gravity is about 0.7984 at 15° C. and its boiling point about 66° C. It is a good solvent for volatile oils, fats, and many resins. When purified it is sold under such names as Columbian Spirit, Colonial Spirit, etc.

It is extensively employed as a denaturing agent for ethyl alcohol and as such is an ingredient in several of the special formulas authorized by the Internal Revenue Department of the U. S. Government (see page 1227).

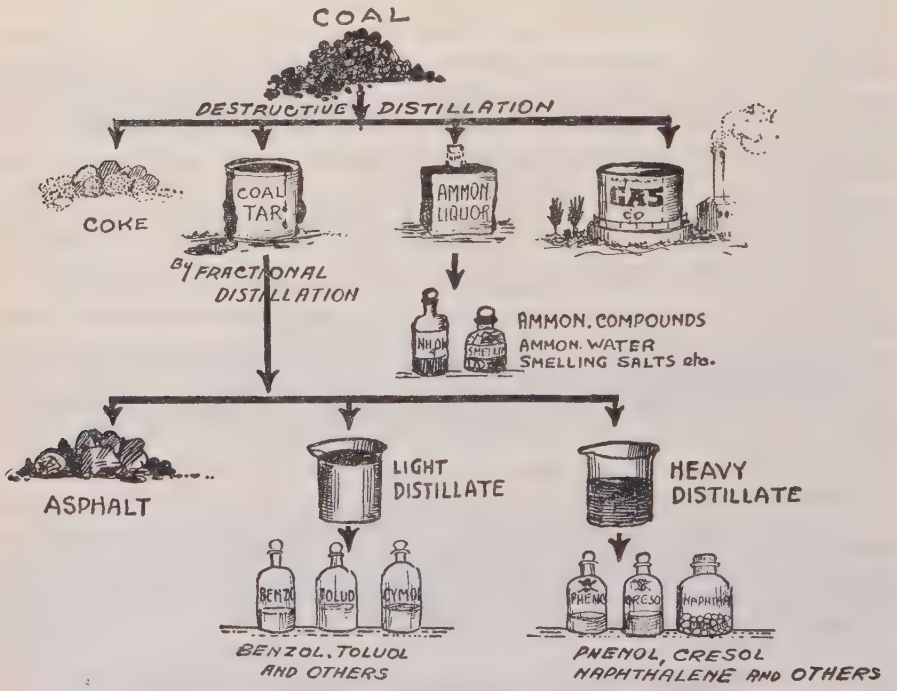
Methanol is very poisonous. It should never be used internally; death and permanent blindness have been produced through the administration of as small quantities as several fluidrachms. The practice of substituting any form of this liquid for ethyl alcohol in pharmaceutical preparations in which it will remain in the finished product is criminal and indefensible.

Products Resulting from the Natural Decomposition of Cellulose and Lignin and Their Derivatives

Coal is fossil fuel, which is found in the earth at various depths, and which has been formed by the decomposition of prehistoric cellulose, and lignin, under the changing influences of moisture, temperature, and pressure to which it has been subjected. The differences in the structure and composition of coal are undoubtedly due to the variations in these influences, as well as to the variations in the character of the vegetable tissues.

When bituminous coal is destructively distilled an exceedingly important group of fractions and products is obtained as explained by the accompanying illustration (Fig. 435), and in the following paragraph under coal tar.

FIG. 435



Products from the destructive distillation of coal

Coal tar is a by-product of the illuminating gas industry. At one time it was considered as worthless and large sums were spent in getting rid of it. Organic chemists had experimented with it because of its complex character and the interesting compounds obtainable from it. In 1856, the English chemist, W. H. Perkin, while making an ineffectual attempt to synthesize quinine, accidentally discovered the first coal-tar color while experimenting with one of the derivatives of coal tar. The value of coal tar became evident and at present it is so necessary to organic chemical manufacture that even if gas were no longer used for illuminating purposes, coal would be subjected to destructive distillation for the sake of the coal tar.

When coal tar is subjected to fractional distillation, a number of valuable commercial products are obtained directly from it. These are properly

termed *coal tar fractions*. The substances of value which are produced by chemical reactions using these coal tar fractions as the starting point, are called *coal tar derivatives* or *synthetics*. Some substances not actually existing in coal tar are so frequently used in the manufacture of synthetics that they are known as *coal tar intermediates*. The term *coal tar product* has been loosely and indefinitely applied to any member of these groups. The first fractions obtained in the distillation of coal tar are complex mixtures in themselves and are called *light oils, middle or carbolic oils, heavy or creosote oils, and anthracene oils*; a non-volatile residue called pitch remaining in the still.

Each of these fractions is subjected to redistillation and the simple products are separated from each other by various chemical and physical methods. Ammonium sulphate is obtained from the aqueous portions of the distillate from coal and a small additional amount is separated from the coal tar itself. Among the fractions of the light oils are *carbon disulphide, pentane, hexane, acetonitrile, benzene, toluene, xylene, cumene,* and other hydrocarbons of the paraffin and benzene series.

From the middle oils are obtained *naphthalene, phenols,* and *cresols*. The heavy oils yield *naphthalene, dinaphthalene, methyl-naphthalene, xylenol, naphthol,* and *paraffins*. The "heavy oil" finds its principal use as a timber preservative, as wood when impregnated with the material under pressure resists decay, and is known as *creosoted lumber*. It will be noted that no creosote, such as obtained from wood tar, is present in this fraction, so the term is a misnomer.

The anthracene oils contain a small amount of phenol, but the main constituent, *anthracene*, is one of the most valuable of all the coal tar fractions. There are also present small amounts of *methylanthracene, phenanthrene, diphenyl, naphthalene, pyrene, retene, carbazol, pyridine, quinoline,* and *aniline*.

Among the more important of the intermediates previously mentioned are *alphanaphthylamine, alphanitronaphthalene, aniline, benzidine, Cleve's acid, cresotinic acid* (also known as *cresotic, homosalicylic* or *toluic acid*), *diasinidine, dimethylaniline, dinitrobenzene, dinitrochlorobenzene, dinitrophenol, dinitrotoluene, diphenylamine, gamma acid, H acid, Laurent's acid, metanitraniline, metaphenylenediamine, metatoluenediamine, mixed mononitrotoluenes, mixed toluidenes, monochlorobenzene, Neville and Winter's acid, nitrobenzene, orthonitrotoluene, orthotoluidine, paraaminophenol, paranitraniline, paranitrochlorobenzene, paranitrotoluene, paratoluidine, picric acid, salicylic acid, sodium metanilate, sodium naphthionate, sodium picramate, sulphanilic acid,* and *toluidine*.

Some of these have valuable uses in medicine and pharmacy, and some are found as coal tar fractions, in amounts too small to be of value, and hence must be prepared synthetically to satisfy the commercial demands.

The coal-tar industry, meaning the industry in which coal tar is used as a starting point, is one of the most important of the chemical industries. It links together the production of synthetic medicines, of artificial dyes and colors, and of munitions.

PIX CARBONIS. N. F. Coal Tar

[**Pix Carbon.**—Pix Lithanthracis N. F. IV]

The tar obtained as a by-product in the destructive distillation of coal in the manufacture of illuminating gas.

Description and Physical Properties—A nearly black, thick liquid or semi-solid, heavier than water and possessing a characteristic, naphthalene-like odor and a sharp burning taste.

It is only slightly soluble in water, to which it imparts its characteristic odor and taste and a faintly alkaline reaction. It is but partially dissolved by alcohol, acetone, methyl alcohol, or

purified petroleum benzin; almost entirely dissolved by ether; entirely dissolved by benzene, carbon disulphide or chloroform.

On ignition it burns with a reddish, luminous and very sooty flame and upon strong heating is almost entirely consumed, leaving not more than 2 per cent of ash.

N. F. Preparation—Liquor Picis Carbonis.

Uses—Used pharmaceutically only in the preparation of the solution (see below).

LIQUOR PICIS CARBONIS. N. F. Coal Tar Solution

[**Liq. Pic. Carbon.**—Liquor Carbonis Detergens]

	Metric	Alternative
Coal Tar	**200 Gm.**	6 oz. av. 296 gr.
Quillaja, in moderately coarse powder	**100 Gm.**	3 oz. av. 148 gr.
Alcohol, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Mix the coal tar and quillaja with 700 cc. [about 22 fl. oz.] of alcohol and macerate the mixture during seven days in a closed vessel, with occasional agitation. Then filter and wash the contents of the filter with sufficient alcohol to make the product measure 1000 cc. [2 pints].

Coal Tar Solution is a yellowish-brown or amber-colored, alcoholic liquid with a characteristic, empyreumatic odor.

Mix 5 cc. of Coal Tar Solution with 100 cc. of water: an opalescent liquid results, which froths abundantly when shaken in a closed vessel. Neither the addition of small amounts of acids nor alkalies noticeably affects the frothing property.

Uses—This preparation is employed externally in the treatment of chronic skin diseases.

BETANAPHTHOL. U. S. Betanaphthol

[**Betanaph.**—Naphthol]

Beta-monohydroxy naphthalene [$C_{10}H_7OH = 144.11$].

Preparation—When naphthalene is digested with fuming sulphuric acid, two acids may be obtained; at a temperature of 80° to 90° C. alphanaphthalene sulphonic acid is chiefly formed, but at 200° C. the beta variety is the principal product, and when this latter acid is fused with an alkali hydroxide and hydrochloric acid added, the official compound, betanaphthol, is liberated.

The fusion of the betanaphthalene sulphonic acid with caustic alkali, and the subsequent liberation of the betanaphthol by treatment with mineral acid, involves reactions that are typical in the synthetic production of the phenols. They are illustrated by the following equations:

$$\underset{\text{betanaphthol sulphonic acid}}{\beta C_{10}H_7HSO_3} + \underset{\text{sodium hydroxide}}{3NaOH} = \underset{\text{sodium betanaphtholate}}{\beta C_{10}H_7ONa} + \underset{\text{sodium sulphite}}{Na_2SO_3} + \underset{\text{water}}{H_2O}$$

then

$$\underset{\text{sodium betanaphtholate}}{\beta C_{10}H_7ONa} + \underset{\text{hydrochloric acid}}{HCl} = \underset{\text{betanaphthol}}{\beta C_{10}H_7OH} + \underset{\text{sodium chloride}}{NaCl}$$

Description and Physical Properties—Colorless or pale buff-colored, shining, crystalline leaflets, or a white or yellowish-white, crystalline powder. It has a faint, phenol-like odor, and is stable in the air.

One Gm. of Betanaphthol is soluble in about 1000 cc. of water, 0.8 cc. of alcohol, 17 cc. of chloroform, and in 1.3 cc. of ether, at 25° C. One Gm. is soluble in 80 cc. of boiling water. It is soluble in glycerin and in olive oil and is readily dissolved by solutions of alkali hydroxides.

It sublimes readily when heated, and volatilizes with the vapors of alcohol and of water.

Tests for Identity—Betanaphthol melts between 120° and 122° C.

A cold, saturated, aqueous solution of Betanaphthol, when mixed with ammonia water, develops a faint, bluish fluorescence.

Add about 0.1 Gm. of Betanaphthol to 5 cc. of an aqueous solution of potassium hydroxide (1 in 4), then add 1 cc. of chloroform, and gently warm the mixture: the aqueous layer acquires a blue color, changing afterward, successively, to green and brown.

Ferric chloride T.S. produces a greenish color in a cold, saturated, aqueous solution of Betanaphthol, and after some time causes the separation of whitish flakes, which turn brown upon the application of heat.

Tests for Purity—Shake 1 Gm. of Betanaphthol with 100 cc. of distilled water at frequent intervals for fifteen minutes, and filter: the filtrate is neutral to litmus paper.

Ash: not more than 0.05 per cent.

Dissolve 0.5 Gm. of Betanaphthol in 25 cc. of ammonia water: no residue remains (*naphthalene*), and the solution does not have a deeper color than pale yellow (*other organic impurities*).

Boil 0.1 Gm. of Betanaphthol with 10 cc. of distilled water until dissolved, allow the solution to cool, and then filter: the addition to the filtrate of 0.3 cc. of normal sodium hydroxide, followed by 0.3 cc. of tenth-normal iodine, produces no violet color (*alphanaphthol*).

Preserve in well-closed containers, protected from light.

N. F. Preparations—Pasta Betanaphtholis; Petroxolinum Betanaphtholis.

Uses—Betanaphthol is used externally as an antiseptic in skin diseases. Internally it is a valuable agent in the treatment of various disorders of the digestive organs. Dose: three to five grains (0.2 to 0.3 Gm.).

CRESOL. U. S. Cresol

A mixture of isomeric cresols [$(C_6H_4.CH_3.OH) = 108.10$] obtained from coal tar.

Preparation—Soon after the introduction of phenol (carbolic acid) into use as an antiseptic it was discovered that some of the homologous constituents of *crude carbolic acid* were more active than the phenol which it contained. Cresol or *cresylic acid*, as it was then called, was the most important among these, and experience has developed its value. Official cresol consists of a mixture of three isomers, existing according to Schulze in coal tar approximately in the proportion of 40 per cent of *metacresol*, 35 per cent of *orthocresol*, and 25 per cent of *paracresol*. Cresol has a higher boiling point than phenol and is separated from it by fractional distillation.

Laws in some states require that preparations of this type shall state upon the label their germicidal activity as compared with phenol. This figure is known as the *Phenol Coefficient* (see *Phenol*).

The official cresol usually shows a phenol coefficient varying from 2 to 3, but higher boiling fractions, known as "tar acids" are also commercially available and these frequently show a phenol coefficient of from 12 to 25. This greatly increased germicidal activity, while indicated by the test organism, the typhoid bacillus, is not equally effective with other common organisms and is therefore misleading. The U. S. P. has intentionally retained a rather limited boiling point product, of uniform and dependable activity, so that when the official products are directed by physicians they may depend upon their efficiency. For the phenol coefficient methods. see page 818.

Description and Physical Properties—A colorless, or yellowish to brown-yellow, or a pinkish, highly refractive liquid, becoming darker with age and on exposure to light. It has a phenol-like, sometimes empyreumatic odor.

One cc. of Cresol is soluble in about 50 cc. of water, usually forming a cloudy solution. It is miscible with alcohol, ether, benzene, petroleum benzin, and with glycerin, and is dissolved by solutions of the fixed alkali hydroxides.

Tests for Identity and Purity—Specific gravity: 1.030 to 1.038 at 25° C.

Not less than 90 per cent by volume of Cresol distils between 195° and 205° C. when determined by Method II, page 121.

A saturated aqueous solution of Cresol is neutral or slightly acid to litmus paper, and becomes bluish-violet on the addition of ferric chloride T.S.

A solution of 1 cc. of Cresol in 60 cc. of distilled water shows no greater turbidity than that produced in 58 cc. of distilled water by the addition of 1.5 cc. of fiftieth-normal sulphuric acid and

1 cc. of barium chloride T.S., comparison being made after the control mixture has been well shaken and allowed to stand for five minutes (*hydrocarbons*).

Preserve in well-closed containers, protected from light.

U. S. P. Preparation—Liquor Cresolis Compositus.

Uses—Cresol is antiseptic and resembles phenol in its medicinal properties, but owing to its greater insolubility in water is nearly always employed in combination with alkalies associated with fatty bodies, or soaps. (See Liquor Cresolis Compositus below.) The dose is one minim (0.06 cc.).

LIQUOR CRESOLIS COMPOSITUS. U. S. **Compound Solution of Cresol**

[Liq. Cresol. Co.]

	Metric	Alternative
Cresol	**500 cc.**	16 fl. oz.
Linseed Oil	**350 cc.**	11 fl. oz. 96 min.
Dekanormal Solution of Potassium Hydroxide	**22 cc.**	338 min.
Dekanormal Solution of Sodium Hydroxide	**88 cc.**	2 fl. oz. 392 min.
Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Mix the cresol and linseed oil, add the dekanormal solutions (see pages 1558 and 1561) and mix well. Heat the mixture to about 70° C. until a portion gives a clear solution when mixed with nine volumes of cold water, cool, and add sufficient water to make the product measure 1000 cc. [2 pints].

NOTE—The 22 cc. [338 min.] of dekanormal solution of potassium hydroxide directed above may be replaced by 14.52 Gm. [212 gr.] of 85 per cent potassium hydroxide and the 88 cc. [2 fl. oz. 392 min.] of dekanormal solution of sodium hydroxide may be replaced by 39.11 Gm. [1 oz. av. 134 gr.] of 90 per cent sodium hydroxide, dissolving the hydroxides in 50 cc. [1 fl. oz. 288 min.] of water. If upon assay the potassium and the sodium hydroxides are found to be of any other strength, a proportionately larger or smaller quantity should be taken.

This liquid was introduced into the Pharmacopœia to supply a need for an antiseptic solution, which will readily mix with water; it closely resembles *lysol, creolin, solveol,* and *solutol* in its medical uses. Some of these preparations produce a milky mixture when added to water, due to the presence of rosin soap instead of an olein soap. Creolin is a preparation of this type, usually employed in from 1 to 3 per cent aqueous solutions. Compound solution of cresol must be used with caution as it is about equal to phenol in its poisonous character.

The U. S. P. now uses a mixture of sodium hydroxide and potassium hydroxide in preparing the soap for this solution, although in the U. S. P. IX the use of only sodium hydroxide was allowed with a great saving in cost. It has been suggested that the pharmacist may readily prepare this solution by dissolving a corresponding weight of linseed-oil soft soap in the cresol and adding sufficient water to make the required quantity. This has been found to be satisfactory if the soap is of proper concentration.

Similar preparations are extensively used as a "*sheep dip*" for the destruction of parasitic organisms in the wool of sheep (see page 816).

The following assay has been added to insure the absence of "higher-boiling-point tar acids" which do not produce an official solution.

Assay—Mix in a 500 cc. distilling flask 50 cc. of Compound Solution of Cresol, accurately measured at 25° C., with 150 cc. of purified kerosene (page 1535). Add 3 Gm. of sodium bicarbonate and distil through an upright condenser, at the rate of not more than two drops per second, until the distillate comes over strongly yellow, receiving the distillate in a 250 cc. to 300 cc. separatory funnel. Run off the lower aqueous layer, shake the kerosene layer with 10 cc. of sulphuric acid (49 to 51 per cent), allow to stand for two hours, then draw off the acid layer completely, and discard it. Add to the kerosene layer 40 cc. of an aqueous sodium hydroxide solution (15 per cent),

accurately measured at 25° C., shake well for five minutes, then allow to stand until complete separation has taken place, and draw off the sodium hydroxide layer into a graduated cylinder. Shake the kerosene layer again with a fresh portion of 20 cc. of the 15 per cent sodium hydroxide solution, accurately measured at 25° C., allow the two layers to separate completely, and draw off the sodium hydroxide layer into the graduated cylinder. Adjust the sodium hydroxide solution in the graduated cylinder to a temperature of 25° C. and note the volume. The difference between the volume noted and the total volume of sodium hydroxide solution used represents the volume of cresol present in 50 cc. of Compound Solution of Cresol. This difference is not less than 23 cc. and not more than 26 cc.

Transfer the sodium hydroxide solution of the cresol obtained in the assay to a separatory funnel and add sufficient hydrochloric acid to render the solution distinctly acid. Allow the precipitated cresol to separate completely and draw off the lower aqueous layer. Wash the cresol with several successive portions of 20 cc. each of a saturated aqueous solution of sodium chloride until the washings are neutral or only slightly acid. Then add to the washed cresol about 5 Gm. of freshly ignited potassium carbonate, shake gently at frequent intervals during three hours, and allow to stand overnight. The cresol decanted from the potassium carbonate meets the distillation requirements for *Cresol*, when determined by Method II, page 121.

Uses—Compound solution of cresol is a valuable disinfectant solution; used chiefly for surgical purposes. It is sometimes used internally in doses of five to ten minims (0.3 to 0.6 cc.).

ORTHOCRESOL. N. F. Orthocresol

The ortho variety of cresol [1:2 $C_6H_4.CH_3OH = 108.10$], obtained from coal tar.

Orthocresol is being made directly from coal tar by fractional distillation and crystallization. The synthetic method for its production involves the sulphonating of toluene whereby the three isomeric toluene sulphonic acids are formed. After converting these into their sodium salts they are fused with caustic soda. This converts them into sodium cresolates which, upon treatment with acid, yield the three isomeric cresols. The orthocresol is then separated by fractional distillation.

Description and Physical Properties—Orthocresol occurs as white crystals or as a colorless or yellow to brown, highly refractive liquid, becoming darker with age and exposure, and having a phenol-like odor.

Slightly soluble in water; soluble in alcohol, ether and chloroform. Miscible with an equal volume of solution of formaldehyde with the production of a transparent solution.

Tests for Identity and Purity—Specific gravity about 1.05; melting point about 30° C.; boiling point about 190° C.

A saturated solution of Orthocresol is neutral or slightly acid to litmus and becomes blue-violet on the addition of ferric chloride T.S.

Preserve it in well-closed containers, protected from light.

N. F. Preparation—Formaldehydum Cresolatum.

Uses—A disinfectant and antiseptic similar in use to the official cresol of which it is a fraction. It was introduced into the N. F. because of its forming a clear solution with formaldehyde in cresolated formaldehyde.

FORMALDEHYDUM CRESOLATUM. N. F. Cresolated Formaldehyde [Formal. Cresol.]

	Metric	Alternative
Orthocresol	40 cc.	2 fl. oz.
Solution of Formaldehyde	60 cc.	3 fl. oz.

Mix them.

Uses—This preparation is used as a toothache remedy, being applied to the cavity on purified cotton.

The following unofficial formulas for preparations of this type may be of value to the pharmacist:

Compound Solution of Crude Cresol

Rosin	300 Gm.
Solution of Potassium Hydroxide (50 per cent)	4.5 cc.
Crude Carbolic Acid (or "Tar Acid", 30 per cent)	600 cc.
Water, a sufficient quantity,	
To make	1000 cc.

Melt the rosin without stirring, and add to it the warmed solution of potassium hydroxide, allow the effervescence to continue for a few minutes until all of the rosin has been saponified, and immediately dissolve the rosin soap in the crude carbolic acid, using as little heat as possible. Finally add water to make 1000 cc.

Sheep Dip

Soap	**1 lb. av.**
Crude Carbolic Acid (or "Tar Acid", 30 per cent)	**16 fl. oz.**
Water	**100 quarts**

Dissolve the soap in a gallon or more of boiling water, add the acid, and stir thoroughly. Any kind of laundry soap may be used. Keep the mixture well thinned in using, and do not let it get into the eyes, mouth, or nostrils of the sheep.

Cresol and Cresol Preparations Recognized by the N. N. R.

Purified Three Cresols, N. N. R.—A mixture of isomeric cresols, corresponding closely to cresol, U. S. P. The phenol coefficient is not less than 2.5 (the value is stated on each package). The phenol toxicity, determined by the method of Hale, is not greater than 150 per cent (the value is stated on each package).

Manufactured by the H. K. Mulford Company, Philadelphia.

Izal, N. N. R.—An albuminous emulsion containing not less than 50 per cent of a liquid, "*izal oil*", which is obtained in the destructive distillation of bituminous coal, and which consists essentially of monatomic phenols boiling between 205° and 300° C. Izal is, therefore, practically free from phenol and cresols.

Actions and Uses—Izal is a germicide and disinfectant. The germicidal efficiency of izal is claimed to have a phenol coefficient of 12, but it is stated to be less toxic than phenol.

Dose—For general use and as a gargle, douche, etc., dilutions of 1: 300 (1 fluidrachm to 1 quart of water) are used. For the disinfection of urine, feces, etc., dilutions of 1: 100 (1 fluidrachm to 1 pint of water) are advised. *Izal is not intended for internal use.*

Manufactured by The Abbott Laboratories, Chicago.

Izal Disinfectant Powder: Izal oil, 10 per cent; naphthalene, 5 per cent; inert, absorbent earth, 85 per cent.

Krelos, N. N. R.—Liquor Cresolis et Phenolis Comp.—A solution of cresols or higher phenol homologues and rosin soap. It is said to represent 60 to 67 per cent of phenols.

A dark brown, almost black, liquid, having a specific gravity of about 1.040 and a characteristic cresol-like odor. With water it forms an almost white, milk-like emulsion.

The phenol coefficient, ranges from 5 to 7, as stated on the label.

Actions and Uses—An antiseptic and germicide.

H. K. Mulford Company, Philadelphia, distributor.

Phenoco, N. N. R.—A mixture of coal-tar creosote and higher phenol homologues, in soap solution. It is said to contain coal-tar creosote, 20 per cent, phenol homologues, 50 per cent, and soap, 30 per cent.

A dark brown fluid of a characteristic odor like that of coal tar. It is miscible with water in all proportions, forming a white emulsion; it is soluble in alcohol, ether, acetone and in fixed oils, forming clear solutions. It is compatible with physiologic salt solution. When tested by the "phenol coefficient" method of the Hygienic Laboratory of the U. S. Public Health Service, it is said to be from twelve to fourteen times stronger, as a germicide, than pure phenol.

Actions and Uses—Phenoco is an antiseptic and germicide, being, in the latter respect, from fifteen to sixteen times stronger than phenol. It is stated to be non-caustic, non-irritant and, for mammals, about one-half as toxic as phenol.

It is used in minor surgery, obstetrics, gynecology, ophthalmology, otology, diseases of the skin, etc.

Dose—Dilutions of from 1 to 5 per cent, or higher, according to the severity of the case.

Manufactured by the West Disinfecting Company, New York.

Creasatin, Dr. N. Sulzberger, N. N. R.—Meta-Cresyl Acetate.—$CH_3C_6H_4.O(CH_3CO)$.—The acetic acid ester of meta-cresol, $CH_3C_6H_4.OH$.

A colorless, oily liquid, possessing a characteristic odor. It is practically insoluble in water, but soluble in the ordinary organic solvents, miscible with liquid petrolatum, fixed and volatile oils and is volatile with steam.

Actions and Uses—It is said to possess antiseptic and analgesic properties, and is apparently free from toxic effects. Useful in the treatment of affections of the nose, throat and ear. It may be employed either in the pure form, or in dilution with oils or alcohol by direct application or spray.

Manufactured by Sharp & Dohme, Baltimore, Md.

Cryogenine, N. N. R.—Phenylsemicarbazide—$C_6H_5.NH.NH.CO.NH_2$.

A white, crystalline powder; odorless; taste slightly bitter. It is soluble in about 100 parts of water at 20° C.; soluble in ether, acetone, chloroform, and benzene. It melts at 172° C.

Actions and Uses—An antipyretic in febrile conditions. An analgesic said to be of value in rheumatism, headache, sciatica, gout and in painful conditions generally. After administration, the urine is highly colored.

Dose—As an antipyretic, 4 to 30 grains (0.25 to 2 Gm.) per day. As an analgesic, from 15 to 45 grains (1 to 3 Gm.) per day.

Manufactured by A. Lumiere, Lyons, France.

PHENOL. U. S. Phenol

[Carbolic Acid]

Phenol (hydroxybenzene) contains not less than 98 per cent of C_6H_5OH (94.08).

Preparation—This valuable product belongs to a well-marked class of phenols of which it is the type. For many years it was made only by distilling crude carbolic acid, and separating and purifying the distillate by repeated

crystallizations, but it is now prepared synthetically by treating benzene or benzol with fuming sulphuric acid to produce benzene-sulphonic acid as follows:

$$\underset{\text{benzene}}{C_6H_6} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{benzene-sulphonic acid}}{C_6H_5SO_2OH} + \underset{\text{water}}{H_2O}$$

This acid is now neutralized with sodium carbonate, forming sodium benzene-sulphonate.

$$\underset{\text{benzene-sulphonic acid}}{2(C_6H_5SO_2OH)} + \underset{\text{sodium carbonate}}{Na_2CO_3} = \underset{\text{sodium benzene-sulphonate}}{2(C_6H_5SO_2ONa)} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{water}}{H_2O}$$

The sodium benzene-sulphonate is fused with caustic soda, whereby sodium phenolate and sodium sulphite are formed as follows:

$$\underset{\text{sodium benzene-sulphonate}}{2(C_6H_5SO_2ONa)} + \underset{\text{sodium hydroxide}}{4NaOH} = \underset{\text{water}}{2H_2O} + \underset{\text{sodium sulphite}}{2Na_2SO_3} + \underset{\text{sodium phenolate}}{2C_6H_5ONa}$$

Hydrochloric acid is finally added to the sodium phenolate, which liberates phenol, which is further purified by distillation. The last reaction is expressed as follows:

$$\underset{\text{sodium phenolate}}{C_6H_5ONa} + \underset{\text{hydrochloric acid}}{HCl} = \underset{\text{phenol}}{C_6H_5OH} + \underset{\text{sodium chloride}}{NaCl}$$

When perfectly pure, phenol is devoid of the odor of cresol, but it has a peculiar aromatic odor, which is not disagreeable. Crystallized phenol, as found commercially, is much purer than the liquid forms, and has the advantage that it may be transported in cans or bottles without risk of loss by leakage. (See Phenol Liquefactum, page 819.)

Description and Physical Properties—Colorless, interlaced, or separate needle-shaped crystals, or a white or light pink, crystalline mass. It has a characteristic, somewhat aromatic odor. When undiluted it cauterizes and whitens the skin and mucous membrane.

One Gm. of Phenol is soluble in about 15 cc. of water at 25° C. It is very soluble in alcohol glycerin, chloroform, ether, carbon disulphide, and in fixed or volatile oils. Soluble in petrolatum and in liquid petrolatum.

When gently heated, phenol melts, forming a highly refractive liquid. It is also liquefied by the addition of about 8 per cent of water. Its vapor is inflammable.

Tests for Identity—Congealing point: not below 39° C.

Its aqueous solution yields with bromine water a white precipitate of tribromphenol, which at first redissolves, but becomes permanent as more of the reagent is added.

Add 1 drop of ferric chloride T.S. to 10 cc. of an aqueous solution of Phenol (1 in 100): the liquid acquires a violet-blue color.

Tests for Purity—An aqueous solution of Phenol (1 in 15) is clear, and neutral or only faintly acid to litmus paper.

Heat about 5 Gm. of Phenol on a water bath: it is volatilized without leaving more than 0.05 per cent of residue.

Assay—Dissolve about 1.5 Gm. of Phenol, accurately weighed, in sufficient distilled water to make 1000 cc. Transfer an aliquot portion of this solution, containing from 0.038 to 0.041 Gm. of Phenol, to a 500 cc. glass-stoppered flask having a long, narrow neck, add 30 cc. of tenth-normal bromine, then 5 cc. of hydrochloric acid, and immediately insert the stopper. Shake the flask repeatedly during half an hour, allow it to stand for fifteen minutes, remove the stopper just sufficiently to introduce quickly 5 cc. of an aqueous solution of potassium iodide (1 in 5), being careful that no bromine vapor escapes, and at once stopper the flask. Shake the latter thoroughly, remove the stopper, and rinse it and the neck of the flask with a little distilled water, so that the washings may flow into the flask, then add 1 cc. of chloroform, shake the mixture well, and titrate with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal bromine corresponds to 0.001568 Gm. of C_6H_5OH.

This assay is explained on page 1468.

Preserve in well-closed containers, protected from light.

U. S. P. Preparations—Glyceritum Phenolis (from Liquefied Phenol); Phenol Liquefactum; Unguentum Phenolis.

N. F. Preparations—Aqua Phenolata (from Liquefied Phenol); Liquor Iodi Phenolatus (from Liquefied Phenol); Liquor Sodii Boratis Compositus (from Liquefied Phenol); Nebula Aromatica; Odontalgicum; Oleum Phenolatum; Petroxolinum Phenolis; Petroxolinum Phenolis Camphoratum; Phenolum Iodatum; Pulvis Antisepticus.

Phenol Coefficient—The disinfectant value of phenol and other germicides largely depends upon their ability to destroy bacteria and other organisms. For a comparison of values pure phenol has been generally adopted as the standard, and the "phenol coefficient" is the ratio of the germicidal power of a disinfectant to the germicidal power of phenol.

Two methods are in general use; the Rideal-Walker Test, largely used in England (published by H. K. Lewis and Company, Ltd., London, England), and the Hygienic Laboratory Method, given below. The U. S. P. has not yet adopted a phenol coefficient method and under the provisions of the Insecticide Act of 1910 it is not necessary for a manufacturer to state the phenol coefficient on the label of a disinfectant. However, if such a statement is made it must comply with the test; some state laws, however, require such statements.

The method recommended by the Hygienic Laboratory of the Public Health Service is published in the Report of July 8, 1921. The process is given below.[1]

Uses—Phenol is one of the most largely used disinfectants and because of this fact great caution must be observed in dispensing it, as it is employed frequently for suicidal purposes. (For treatment of poisoning, see Antidotes, Part XV.) When applied to the skin or mucous membrane, it cauterizes and produces blanching; alcohol applied at once to the cauterized part causes the disappearance of the white spots. When diluted with an equal volume of glycerin, it becomes miscible with water in any proportion (see Glyceritum Phenolis, page 301).

---

[1] **DISINFECTANT TESTING BY THE HYGIENIC LABORATORY METHOD**

The following method for determining the phenol coefficient of disinfectants supersedes the methods described in previous publications of the Public Health Service, and is the present Hygienic Laboratory Method.

No single method can serve as a means of comparing the value in practice of disinfectants of greatly diverse composition and destined for a variety of applications. However, disinfectants which are chemically related to phenol, which are to be used against organisms reacting similarly to the manner in which the typhoid bacillus reacts and which are destructive within the time and temperature limits of this test, may be compared as to their disinfecting properties within these limitations by means of this test. The results may be useful in the selection of a potent product, in making comparisons of cost in terms of service rendered, and in checking successive batches of the same product.

This method was submitted to several different laboratories for trial before its adoption, and the results seem to justify the belief that the personal equation in the performance of the tests does not play an inordinate rôle.

THE TEST CULTURE

The test culture is a culture of *Bacillus typhosus*, Hopkins strain. Between periods of testing it is maintained on nutrient agar stabs, transferred at monthly intervals.

For at least five days before the test the culture is transferred at 24-hour intervals to successive tubes of the meat extract broth described below and incubated at 37° C. Transfers are made with one standard loopful. The culture is filtered through sterile filter paper just before using. The test is performed with a 24-hour culture.

THE PHENOL

The phenol must comply with the requirements of the Eighth United States Pharmacopœia. Particularly the congealing point must not be below 40° C. The crystals are kept in tightly stoppered amber-colored bottles in a dark and relatively cool place.

A 5 per cent original solution is made by adding 1 part by weight of phenol, liquefied by warming the bottle, to 19 parts of distilled water. A fresh solution is made for each day's use.

THE CULTURE MEDIUM

Make meat extract medium as follows:

Beef extract (Liebig's)	3 Gm.
Peptone (Armour's for disinfectant testing)	10 Gm.
Sodium chloride	5 Gm.
Water, distilled	1,000 cc.

Boil for 15 minutes.
Make up to original weight by addition of water.
Filter through paper.
Tube, 10 cc. to each tube.
Sterilize.
The pH value of this medium should be between 6.0 and 7.0.

Phenol is used internally in the treatment of various digestive disorders and as a urinary antiseptic. The dose is one grain (0.06 Gm.). As an external remedy it is used for its anesthetic and antiseptic action in skin diseases. It is also largely used as a local application in nose and throat infections and as a surgical disinfectant.

Average dose—1 grain (0.06 Gm).

PHENOL LIQUEFACTUM. U.S. Liquefied Phenol

[**Phenol Liq.**—Liquefied Carbolic Acid]

Phenol liquefied by mixing with 10 per cent of water. It contains not less than 88 per cent of C_6H_5OH (94.08).

Phenol, a convenient quantity.
Distilled Water, a sufficient quantity.

Liquefy the phenol by placing the unstoppered container in a water bath and apply heat gradually until it is melted. Transfer the liquid to a tared vessel, weigh, and add 1 Gm. [1 oz. av.] of distilled water for each 9 Gm. [9 oz. av.] of phenol and mix thoroughly.

On standing, liquefied phenol becomes pink or red in color. It is claimed that the immersion of a few strands of wool yarn will remove the color, the wool becoming dyed, and the phenol restored to its original appearance.

Description and Physical Properties—A colorless liquid, which may develop a red tint upon keeping. It has a characteristic, somewhat aromatic odor. When undiluted it cauterizes and whitens the skin and mucous membrane.

Liquefied Phenol is miscible with alcohol, ether, and glycerin. When diluted with an equal volume of glycerin, the mixture is miscible with water.

Tests for Identity and Purity—Specific gravity: about 1.065 at 25° C.

When subjected to distillation, the boiling point does not rise above 182° C.

GLASSWARE AND APPARATUS

Glassware for measuring must be accurately graduated. It must be clean, dry, and sterile at the time of use. There will be needed—

1 cc. capacity pipettes.
5 cc. capacity pipettes.
1 cc. delivery pipettes, graduated in tenths.
5 cc. delivery pipettes.
100 cc. measuring cylinders, graduated in 1 cc., glass stoppered.
Seeding tubes, 1 x 3 inches, flared tops, round bottoms.

Racks consisting of blocks of wood with rows of holes for both the seeding tubes (before they are placed in the water bath) and the subculture tubes.

Wire loops must be carefully made and kept from damage. They are made as follows: A close cylindrical spiral is made by winding a piece of platinum wire, No. 23, B. & S. gauge, as tightly as possible about a piece of steel or other hard wire having a diameter of 0.072 inch (No. 13, B. & S. gauge) to complete a little more than four full turns. The long end of the wire is then bent sharply at right angles to the wound portion and parallel to the steel wire. The core is removed and the short end of the wire is clipped off so as to leave exactly four full turns to the coil. The successive turns of the spiral must touch one another continuously. The long end of the wire is attached to an aluminum handle.

A convenient support is provided on which to rest the loops so that a batwing Bunsen burner may be placed under each one successively.

A constant temperature bath is provided, capable of maintaining the seeding tubes at 20° C. during the time of the test. A well-insulated bath of large volume relative to the surface exposed is sufficient without thermo-regulating appliances.

Disinfectant Testing Machine—The use of a disinfectant testing machine is optional. One is described in Reprint No. 462 from the Public Health Reports. A few modifications have proved useful. For example, the use of platinum instead of nichrome loops, and the practice of sterilizing the subculture tubes covered with padded inverted troughs in the racks.

DILUTIONS

Dilutions of phenol and of disinfectants are made from the original liquid on the day of the test. For the dilutions of the disinfectant, a 5 per cent solution is made by adding 5 cc. of the disinfectant to 95 cc. of sterile distilled water. A standardized 5 cc. capacity pipette is used for this purpose. After filling the pipette, all excess of the disinfectant on the outside of the pipette is wiped off with sterile gauze. The contents of the pipette are then delivered into a cylinder containing 95 cc. of sterile distilled water and the pipette is washed out as clean as possible by aspiration and blowing out the contents into the cylinder. The contents of the cylinder are then thoroughly shaken and the dilutions up to 1 : 500 are made from it, using delivery pipettes for measuring. For those disinfectants which do not readily form a 5 per cent solution make a 1 per cent solution, and from this make the dilutions greater than 1 : 100 in accordance with the second table of dilutions. If greater dilutions than 1 : 500 are to be made, a 1 per cent solution is made from the 5 per cent solution and the higher dilutions are made from this.

In other respects Liquefied Phenol responds to the tests for identity and purity under *Phenol*, omitting the congealing point.

Assay—Proceed as directed under *Phenol*.

NOTE—When Phenol is to be mixed with fixed oils, liquid petrolatum, or petrolatum, use melted crystalline phenol instead of Liquefied Phenol.

Preserve in well-closed containers, protected from light.

U. S. P. Preparations—Glyceritum Phenolis; Unguentum Phenolis.

N. F. Preparations—Aqua Phenolata; Liquor Iodi Phenolatus; Liquor Sodii Boratis Compositus.

Uses—Liquefied phenol was introduced into the Pharmacopœia to furnish a uniform and convenient method of using phenol in a concentrated liquid form. The practice of adding 10 per cent of water to crystallized phenol has long been followed, this liquid being often more convenient for compounding prescriptions than the crystals. In using it, allowance must of course be made for the presence of 10 per cent of water. The dose is one minim (0.06 cc.).

PHENOL IODATUM. N.F. Iodized Phenol

[**Phenol Iodat.**—ACIDUM CARBOLICUM IODATUM]

	Metric	Alternative
Iodine, reduced to powder	**20 Gm.**	2 oz. av.
Phenol	**60 Gm.**	6 oz. av.
Glycerin	**20 Gm.**	2 oz. av.
To make	**100 Gm.**	10 oz. av.

Place the iodine in a flask, add the phenol, then the glycerin, and digest the mixture at a gentle heat, frequently agitating, until the iodine is dissolved.

Preserve the product in glass-stoppered bottles in a dark place.

Uses—It is used as an antiseptic and caustic.

For the higher dilutions, delivery pipettes may be used. The following scale is used for making dilutions:

For dilutions up to 1 : 70, increase or decrease by a difference of 5 (*i.e.*, 5 parts of water); from 1 : 70 to 1 : 160, by a difference of 10; from 1 : 160 to 1 : 200, by a difference of 20; from 1 : 200 to 1 : 400, by a difference of 25; from 1 : 400 to 1 : 900, by a difference of 50; from 1 : 900 to 1 : 1800, by a difference of 100; from 1 : 1800 to 1 : 3200, by a difference of 200; and so on if higher dilutions are necessary.

It is important that the cylinders used for making the dilutions be correctly graduated. It is preferable to use standardized cylinders and pipettes. For making the dilutions in accordance with the above scheme, the following tables are of service:

Tables useful in making dilutions

[5 cc. of disinfectant + 95 cc. of distilled water = Solution A]

Dilution	cc. of A	cc. of dist. water	cc. of A	cc. of dist. water	cc. of A	cc. of dist. water
1 : 20 =	20 +	0 or 10 +	0	or 4 +	0	
1 : 25 =	20 +	5 or 10 +	2½	or 4 +	1	
1 : 30 =	20 +	10 or 10 +	5	or 4 +	2	
1 : 35 =	20 +	15 or 10 +	7½	or 4 +	3	
1 : 40 =	20 +	20 or 10 +	10	or 4 +	4	
1 : 45 =	20 +	25 or 10 +	12½	or 4 +	5

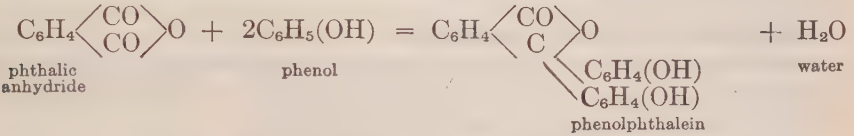
PHENOLPHTHALEINUM. U.S. Phenolphthalein

[Phenolphthal.]

$(C_6H_4OH)_2CO.C_6H_4CO(318.21)$

A compound resulting from the condensation of phthalic anhydride with phenol, and with the elimination of water.



Preparation—It may be prepared by heating 10 parts of phenol with 5 parts of phthalic anhydride and 4 parts of sulphuric acid to 120° C. for ten or twelve hours, exhausting the product with boiling water, dissolving the residue in dilute sodium hydroxide solution, filtering, and precipitating with acetic acid. It is afterwards purified and crystallized.

Description and Physical Properties—A white or faintly yellowish-white, crystalline powder. It is odorless, and is stable in the air.

Phenolphthalein is almost insoluble in water. One Gm. is soluble in 13 cc. of alcohol, and in about 70 cc. of ether, at 25° C.

Test for Identity—Melting point not below 256° C.

It is readily dissolved by solutions of alkali hydroxides and by hot solutions of alkali carbonates, yielding a red liquid. These solutions are decolorized by the addition of an excess of acid.

Tests for Purity—Ash: not more than 0.05 per cent.

A solution of 0.5 Gm. of Phenolphthalein in 30 cc. of neutral alcohol is colorless.

One-half Gm. of Phenolphthalein dissolves completely in a mixture of 4 cc. of sodium hydroxide T.S. and 50 cc. of distilled water (*fluorane*).

A mixture of 250 cc. of cold, recently boiled, distilled water and 0.5 cc. of a solution of Phenolphthalein (1 in 100) in alcohol, requires not more than 0.25 cc. of fiftieth-normal sodium hydroxide to produce a pink color.

Heat 0.5 Gm. of Phenolphthalein with 10 cc. of diluted hydrochloric acid on a water bath for five minutes, filter, and evaporate the filtrate to dryness. The residue dissolved in 25 cc. of dis-

1 : 3,200 =	5	+ 155	or 4	+ 124	or 2	+ 62

METHOD

This description applies to the hand method. For the use of the machine, follow the procedure of Reprint No. 462 from the Public Health Reports.

The object is to add 0.1 cc. of typhoid culture to 5 cc. of successive dilutions of the disinfectant and of

tilled water, slightly acidulated with hydrochloric acid, meets the requirements of the test for *heavy metals*, page 1519.

Heat a crucible to redness, and introduce, in small portions, an intimate mixture of 0.2 Gm. of Phenolphthalein, 0.5 Gm. of potassium nitrate, and about 0.3 Gm. of anhydrous sodium carbonate. Maintain a red heat until the reaction ceases, then boil the cooled residue for five minutes with 10 cc. of diluted sulphuric acid, filter, and wash the undissolved residue with 10 cc. of distilled water. Evaporate the filtrate and washings until sulphuric acid vapors begin to evolve. The residue dissolved in 5 cc. of distilled water conforms to the requirements of the test for *arsenic*, page 1512.

N. F. Preparation—Tabellæ Phenolphthaleini.

Uses—Phenolphthalein has been used for a number of years as an indicator in volumetric analysis, but it is now largely employed internally as a purgative in doses of one-half to three grains (0.03 to 0.2 Gm.).

Average dose—1 grain (0.06 Gm.).

PHENOLSULPHONPHTHALEINUM. U. S. Phenolsulphonphthalein

(See Chapter on Coloring Principles, page 846.)

TRINITROPHENOL. U. S. Trinitrophenol

[**Trinitrophen.**—Picric Acid]

$C_6H_2(OH)(NO_2)_3$ 1 : 2 : 4 : 6 (229.08).

Caution—For safety in transportation it is usually mixed with about 20 per cent of water. Before applying the tests described below, dry the Trinitrophenol to constant weight in a desiccator over sulphuric acid.

Preparation—It is obtained by nitrating phenolsulphonic acid, which is made by the action of concentrated sulphuric acid on phenol.

Description and Physical Properties—Pale yellow, rhombic prisms or scales. It is odorless and has an intensely bitter taste.

Caution—Trinitrophenol explodes when heated rapidly or when subjected to percussion.

One Gm. of Trinitrophenol is soluble in 78 cc. of water, 12 cc. of alcohol, 35 cc. of chloroform, 65 cc. of ether, and in 10 cc. of benzene, at 25° C. One Gm. is soluble in 15 cc. of boiling water.

Tests for Identity—Trinitrophenol melts between 121° and 123° C.

An aqueous solution of Trinitrophenol is acid to litmus paper.

An aqueous solution of Trinitrophenol (1 in 100) has a yellow color, which becomes more intense on the addition of alkalies, and red on the addition of ammonium sulphide T.S. or a solution of an alkaline cyanide.

An aqueous solution of Trinitrophenol is precipitated by solutions of most alkaloidal salts.

Tests for Purity—Add 5 drops of barium chloride T.S. to 10 cc. of an aqueous solution of Trinitrophenol (1 in 100): the liquid does not at once become opalescent (*sulphate*).

---

phenol, and, after this addition, to transfer a loopful of each mixture to a separate subculture tube at periods of 5, 7½, 10, 12½, and 15 minutes. The subculture tubes are then incubated for 48 hours at 37° C., and readings of growth or no growth are made and recorded.

Dilutions are made to cover the expected range of the disinfectant, and 5 cc. of each dilution is placed in a seeding tube. Dilutions of phenol are made as follows: 1 : 80, 1 : 90, 1 : 100, 1 : 110, 1 : 120, and 1 : 130, and 5 cc. of each is placed in a seeding tube.

The seeding tubes are placed in the water bath at 20° C. and a few minutes are allowed for their contents to reach this temperature.

To each seeding tube 0.1 cc. of culture is then added seriatim, allowing 15 seconds for each addition. If there are 10 tubes of disinfectant dilutions, this will occupy 2½ minutes. At the end of five minutes from the time of adding the disinfectant to the first seeding tube, a loopful of the mixture is transferred from this tube to a subculture tube, and this is done from each successive seeding tube at 15-second intervals. This procedure is repeated after the lapse of 7½, 10, 12½, and 15 minutes from the time of the first addition of culture to the seeding tube. Each loop is placed on the support and flamed with the Bunsen burner immediately after use, and the use of several loops permits them to cool before they are needed again. The operator is therefore obliged to make a transfer every 15 seconds for 10 minutes.

The culture is best added to the seeding tube by holding the latter in a slanting position and touching the tip of the 1 cc. pipette to the wetted surface exposed on its upper side. One-tenth cc. is run in at the proper time and thorough admixture is assured by gentle shaking.

The dilutions of phenol are next treated in the same manner as those of the disinfectant.

The tubes are properly labeled and are placed in the incubator for 48 hours, at the end of which time readings of growth or no growth are made and entered in a table as + or − signs, respectively.

In the nature of the test it is unavoidable that discrepancies in the even oblique slant of the plus signs across the chart will occasionally be encountered; but if these are numerous, a faulty technic is indicated and the test should be discarded. The same applies to accidentally contaminated tubes.

Dissolve 2 Gm. of Trinitrophenol is 50 cc. of benzene, collect the insoluble residue, if any, on a small counterpoised filter, or in a Gooch crucible with an asbestos layer, which has been dried at 100° C. and weighed, and wash the residue and filter with benzene until the washings are colorless: the residue, dried at 100° C., does not exceed 0.2 per cent.

Preserve in well-stoppered bottles, in a cool place, remote from fire.

Uses—It is used as an antiseptic in the form of a 1 per cent aqueous solution for burns; also used for its astringent and antiseptic effect in skin diseases. In urinalysis it is employed as a reagent to detect and estimate albumin. It is very explosive when dry, therefore the above caution concerning transportation. It has been employed internally as an antipyretic; the dose is one-half grain (0.03 Gm.).

RESORCINOL. U.S. Resorcinol

[**Resorcin.**—Resorcin, Metadioxybenzene]

Resorcinol, when dried to constant weight over sulphuric acid, contains not less than 99.5 per cent of $C_6H_4(OH)_2$ 1:3 (110.08).

Preparation—Resorcinol is usually prepared by fusing sodium metabenzenedisulphonate with sodium hydroxide; it may be made in several other ways—by the destructive distillation of brazilin, or by the fusion of either galbanum, ammoniac, sagapenum, asafetida, or acroides with caustic potash. Resorcinol is a dihydric phenol isomeric with *pyrocatechin* and *hydroquinone*.

The first method of preparation referred to is a general one for the production of phenols and may be illustrated, as applied to resorcinol, by the following equations:

$$C_6H_4(NaSO_3\,①)(NaSO_3\,③) + 4NaOH = C_6H_4(ONa\,①)(ONa\,③) + 2Na_2SO_3 + 2H_2O$$

sodium metabenzenedisulphonate — sodium hydroxide — sodium resorcinolate — sodium sulphite — water

$$C_6H_4(ONa\,①)(ONa\,③) + 2HCl = C_6H_4(OH\,①)(OH\,③) + 2NaCl$$

sodium resorcinolate — hydrochloric acid — resorcinol — sodium chloride

Description and Physical Properties—Colorless, or nearly colorless, needle-shaped crystals, or powder. It has a faint, characteristic odor and a sweetish, followed by a bitter, taste. It acquires a pink tint on exposure to light and air.

One Gm. of Resorcinol is soluble in 0.9 cc. of water and in 0.9 cc. of alcohol, at 25° C. One Gm.

DETERMINATION OF COEFFICIENT

The coefficient is the arithmetical mean of the sum of three ratios, expressed decimally. These ratios are the denominator of the highest dilution of the disinfectant in whose subculture tube no growth occurs, divided by the corresponding figure for phenol, for the 5, 10, and 15 minute intervals, respectively.

Example:

Sample	Dilution	Time of exposure in minutes				
		5	7½	10	12½	15
Disinfectant	1 : 700	−	−	−	−	−
	1 : 800	+	−	−	−	−
	1 : 900	+	+	−	−	−
	1 : 1,000	+	+	+	+	−
	1 : 1,000	+	+	+	+	+
Phenol	1 : 80	−	−	−	−	−
	1 : 90	+	−	−	−	−
	1 : 100	+	+	+	+	−
	1 : 110	+	+	+	+	−
	1 : 120	+	+	+	+	+
	1 : 130	+	+	+	+	+

$$\text{Coefficient} = \frac{\frac{700}{80} + \frac{900}{90} + \frac{1000}{110}}{3} = \frac{8.7 + 10.0 + 9.0}{3} = 9.2$$

is soluble in about 0.2 cc. of water at 80° C. It is freely soluble in glycerin and in ether, and is slightly soluble in chloroform.

Tests for Identity—Resorcinol melts between 109° and 111° C.

The addition of three drops of ferric chloride T.S. to 10 cc. of an aqueous solution of Resorcinol (1 in 200) produces a bluish-violet color, changing to brownish-yellow on the addition of ammonia T.S. (*difference from catechol and quinol*).

Dissolve 0.1 Gm. of Resorcinol in 2 cc. of sodium hydroxide T.S., add a drop of chloroform, and heat the mixture: an intense crimson color is produced, which changes to pale yellow on the addition of a slight excess of hydrochloric acid.

Tests for Purity—Its aqueous solution (1 in 20) is neutral or only faintly acid to litmus paper.

Ash: not more than 0.05 per cent.

An aqueous solution of Resorcinol (1 in 20) does not emit the odor of phenol when gently warmed.

Lead acetate T.S. produces no precipitate in an aqueous solution of Resorcinol (1 in 20) (*catechol*).

Assay—Dissolve about 1.5 Gm. of Resorcinol, previously dried to constant weight over sulphuric acid and accurately weighed, in sufficient distilled water to make 500 cc. Transfer 25 cc. of this solution, representing one-twentieth of the weight of Resorcinol taken, to a 500 cc. glass-stoppered flask having a long, narrow neck, add 50 cc. of tenth-normal bromine, dilute with 50 cc. of distilled water, add 5 cc. of hydrochloric acid, and at once stopper the flask. Shake, allow it to stand for one minute, dilute with 20 cc. of distilled water, add 5 cc. of potassium iodide T.S., allow to stand for five minutes, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal bromine corresponds to 0.001835 Gm. of $C_6H_4(OH)_2$.

This assay is explained on page 1468.

Preserve in well-closed containers, protected from light.

N. F. Preparations—Curatio Paraffini; Pasta Resorcinolis Fortis; Pasta Resorcinolis Mitis; Unguentum Resorcinolis Compositum.

Uses—Resorcinol is an antiseptic closely resembling phenol in its physiological action but less powerful. It is used mainly externally in various skin diseases. Occasionally it is given internally as a gastric antiseptic. The dose of resorcinol is two to three grains (0.12 to 0.2 Gm.).

Unofficial Compounds of Resorcinol

Euresol, N. N. R.—Resorcin Monacetate.—Resorcinyl Acetate—$CH_3.CO.O.(C_6H_4.OH)$—The acetic acid ester of resorcinol, $C_6H_4(OH)_2$, 1: 3.

A thick, honey-yellow, oily liquid, boiling at 283° C. and soluble in acetone.

Actions and Uses—Its action is similar to that of resorcinol, but milder and more lasting because of the gradual liberation of the phenol.

Euresol is said to be useful in acne, sycosis, chilblains, and particularly in the treatment of alopecia and seborrhea. Applied pure, in acetone solution, and as a 5 to 50 per cent ointment. For scalp lotions, from 3 to 5 per cent alcoholic solutions are used.

Manufactured by E. Bilhuber, Inc., New York.

Hexylresorcinol—Caprokol—A synthetic chemical, $C_6H_3(OH)_2C_6H_{13}$, said to possess about 45 times the germicidal power of Phenol.

An internal urinary antiseptic, indicated in the treatment of infections of the urinary tract. Claimed to be non-toxic in therapeutic doses. Administered in capsules, in oil solution, in doses of two and one-half grains (0.15 Gm.).

Manufactured by Sharp and Dohme, Baltimore, Md.

ACIDUM SALICYLICUM. U. S. Salicylic Acid

[Acid. Salicyl.—Orthohydroxy Benzoic Acid]

Salicylic Acid, dried at 100° C. for two hours, contains not less than 99.5 per cent of $C_6H_4(OH).COOH$ 1: 2 (138.08).

Preparation—Although salicylic acid may be obtained from several natural sources, it is obtained, according to Kolbe's patent, by treating sodium phenol (or carbolate) with carbon dioxide. For this purpose, the most concentrated caustic soda solution is evaporated with the corresponding amount of phenol to a dry powder; this is then heated to 100° C. while a stream of dry carbon dioxide is passed over it. The temperature is gradually raised to 180° C. and increased to 220° C. as soon as phenol distils over, and finally raised to 250° C. until no more phenol distils. The residue left in the retort is essentially composed of sodium sodio-salicylate, ($C_6H_4ONaCOONa$). In the retort, the

half of the phenol used remains as sodium salicylate, while the other half is distilled over unchanged. The reactions are expressed as follows:

$$\underset{\text{phenol}}{C_6H_5OH} + \underset{\text{sodium hydroxide}}{NaOH} = \underset{\text{sodium-phenol}}{C_6H_5ONa} + \underset{\text{water}}{H_2O}$$

$$\underset{\text{sodium-phenol}}{2C_6H_5ONa} + \underset{\text{carbon dioxide}}{CO_2} = \underset{\text{phenol}}{C_6H_5OH} + \underset{\text{sodium sodio-salicylate}}{C_6H_4\begin{cases}ONa\ ①\\COONa\ ②\end{cases}}$$

The sodium salt thus obtained is dissolved in water and decomposed by hydrochloric acid as follows:

$$\underset{\text{sodium sodio-salicylate}}{C_6H_4\begin{cases}ONa\ ①\\COONa\ ②\end{cases}} + \underset{\text{hydrochloric acid}}{2HCl} = \underset{\text{salicylic acid}}{C_6H_4\begin{cases}OH\ ①\\COOH\ ②\end{cases}} + \underset{\text{sodium choride}}{2NaCl}$$

The salicylic acid is then filtered off, washed, and crystallized from a hot aqueous solution, or purified by sublimation in a current of superheated steam or dialyzed.

In Schmitt's improved method carbon dioxide reacts upon sodium-phenol, in closed vessels at a temperature of 130° C., forming sodium-phenol carbonate which passes into sodium salicylate. By this modification no separation of phenol occurs. Salicylic acid is also made from oil of gaultheria by adding to it a strong solution of potassium hydroxide whereby potassium salicylate is formed; this is then poured into diluted hydrochloric acid and the separated crystals of salicylic acid purified by recrystallization.

Description and Physical Properties—Fine needles, or a bulky crystalline powder. It has a sweetish, afterwards acrid taste, and is stable in the air.

Synthetic Salicylic Acid is white and odorless. When prepared from natural methyl salicylate, the Acid may have a slightly yellow or pink tint, and a faint, gaultheria-like odor.

One Gm. of Salicylic Acid is soluble in 460 cc. of water, 2.7 cc. of alcohol, 42 cc. of chloroform, 3 cc. of ether, 3 cc. of acetone, 135 cc. of benzene, and in 52 cc. of oil of turpentine, at 25° C. One Gm. is soluble in about 15 cc. of boiling water.

Tests for Identity—Salicylic Acid melts between 157° and 159° C.

Salicylic Acid responds to the reactions for salicylates, page 826.

Tests for Purity—Ash: not more than 0.05 per cent.

Allow a solution of 1 Gm. of Salicylic Acid in 3 cc. of alcohol to evaporate spontaneously in a glass or porcelain dish, protected from dust: the synthetic Acid yields a white, crystalline residue, while the Acid prepared from natural methyl salicylate yields a white, or not more than a slightly yellow, or a slightly pink residue (*coloring matter*).

Dissolve 1 Gm. of Salicylic Acid in an excess of cold sodium carbonate T.S., agitate the liquid with an equal volume of ether, separate the ether layer, and allow it to evaporate spontaneously: the residue, if any, is free from the odor of phenol.

A solution of 0.5 Gm. of the synthetic Salicylic Acid in 10 cc. of sulphuric acid acquires not more than a light yellow color. The Acid prepared from natural methyl salicylate under similar conditions may produce a slightly brown color (*readily carbonizable substances*).

Dissolve 0.5 Gm. of Salicylic Acid in 10 cc. of alcohol containing a few drops of nitric acid: the solution is unaffected by the addition of a few drops of silver nitrate T.S. (*chloride*).

Assay—Dissolve about 0.5 Gm. of Salicylic Acid, previously dried at 100° C. for two hours and accurately weighed, in 25 cc. of diluted alcohol, which previously has been neutralized with tenth-normal sodium hydroxide, using phenolphthalein T.S. as indicator. Titrate the solution with tenth-normal barium hydroxide until the pink color is restored. Each cc. of tenth-normal barium hydroxide corresponds to 0.01381 Gm. of $C_6H_4(OH).COOH$.

This assay is explained on page 1456.

N. F. Preparations—Collodium Salicylicum Compositum; Glycerogelatinum Acidi Salicylici; Mulla Acidi Salicylici; Mulla Creosoti Salicylata; Pasta Zinci; Pulvis Antisepticus; Pulvis Talci Compositus; Stili Acidi Salicylici Dilubilis.

Uses—Salicylic acid is used internally in rheumatism and as an analgesic, also as a urinary antiseptic. Externally it is used in skin diseases for its antiseptic effect and also its power of softening the keratin of the skin; it is the latter effect which explains its value in "corn-plasters". The dose is eight grains (0.5 Gm.). A number of salts of the acid are official—ammonium, bismuth, phenyl, quinine, strontium, sodium, and acetylsalicylic acid; methyl salicylate is an official liquid. The sodium salt is very valuable, and is generally relied upon for the internal administration of the acid.

Tests for Salicylates

Salicylates—In moderately dilute solutions of salicylates, ferric chloride T.S. produces a violet color. The addition of acids to moderately concentrated solutions of salicylates produces a precipitate of salicylic acid.

PHENYLIS SALICYLAS. U.S. Phenyl Salicylate

[**Phenyl. Salicyl.**—SALOL]

$C_6H_4(OH)COOC_6H_5$ 1:2 (214.15).

Preparation—Phenyl salicylate is prepared by heating salicylic acid with phenol in the presence of certain acid chlorides (phosphoryl chloride or carbonyl chloride); the elements of water are withdrawn by this action, and the phenyl group is caused to unite with the salicylic radical.

The reaction is expressed thus:

$$2C_6H_4\begin{cases}OH\ ①\\COOH\ ②\end{cases} + 2C_6H_5OH + POCl_3 =$$

salicylic acid — phenol — phosphoryl chloride

$$2C_6H_4\begin{cases}OH\ ①\\COOC_6H_5\ ②\end{cases} + HPO_3 + 3HCl$$

phenyl salicylate — metaphosphoric acid — hydrochloric acid

Description and Physical Properties—A white, crystalline powder, having an aromatic odor, and a characteristic taste.

One Gm. of Phenyl Salicylate is soluble in 6670 cc. of water and in 6 cc. of alcohol, at 25° C. It is very soluble in chloroform, ether, benzene, and in fixed or volatile oils.

Tests for Identity—It melts between 41° and 43° C.

Heat about 0.3 Gm. of Phenyl Salicylate with 3 cc. of sodium hydroxide T.S. for a few minutes and then acidify the solution with hydrochloric acid: salicylic acid separates and the odor of phenol is recognizable.

The addition of diluted ferric chloride T.S. to an alcoholic solution of the salt (1 in 20) produces a violet color.

Test for Purity—Phenyl Salicylate does not redden moistened blue litmus paper (*free acid*).

Ash: not more than 0.05 per cent.

Shake 1 Gm. of Phenyl Salicylate with 50 cc. of distilled water and filter the liquid: the addition of one drop of ferric chloride T.S. to 10 cc. of the filtrate produces no violet color (*uncombined phenol or salicylic acid*).

Ten cc. portions of the filtrate prepared for the preceding test, when tested separately with barium nitrate T.S. and silver nitrate T.S., show no turbidity (*sulphate or chloride*).

Preserve in well-closed containers, in a cool place.

Uses—Phenyl salicylate is used as an intestinal antiseptic, it being decomposed in the small intestine, when in contact with alkaline fluids, into phenol and salicylic acid. It is also employed as a mild antirheumatic and analgesic. It is also used pharmaceutically to coat pills by rolling them in the salol, fused at a low temperature, forming what are termed *enteric pills*, intended to pass through the stomach unaltered, the salol being insoluble in the stomach (see page 1731). The dose is from five to thirty grains (0.3 to 2 Gm.).

ACIDUM ACETYLSALICYLICUM. U. S. Acetylsalicylic Acid

[Acid. Acetylsal.—Aspirin, Empirin]

Acetylsalicylic Acid contains not less than 99.5 per cent of $C_6H_4.O(CH_3CO).COOH$ 1:2 (180.11).

The acetyl derivative of salicylic acid, prepared by the action of acetic anhydride or acetyl chloride on salicylic acid. Condensation takes place as follows:

$$(CH_3CO)_2O + 2C_6H_4\begin{matrix}OH\ ① \\ COOH\ ②\end{matrix} = 2C_6H_4\begin{matrix}OCH_3CO\ ① \\ COOH\ ②\end{matrix} + H_2O$$

acetic anhydride — salicylic acid — acetyl salicylic acid — water

Description and Physical Properties—Small, colorless crystals or needles, or a white, crystalline powder. It is odorless, and in dry air is stable, but in contact with moisture it gradually decomposes into salicylic and acetic acids.

One Gm. of Acetylsalicylic Acid is soluble in about 300 cc. of water, 5 cc. of alcohol, 17 cc. of chloroform, and in from 10 to 15 cc. of ether, at 25° C. It is less soluble in absolute ether. It is also soluble with decomposition in solutions of alkali hydroxides and carbonates.

Tests for Identity—The melting point of Acetylsalicylic Acid, when determined in a bath previously heated to 120° C., is not below 132° C.

When the Acid is heated with water for several minutes, then cooled and a drop or two of ferric chloride T.S. added, a violet-red color is produced.

Boil about 0.5 Gm. of Acetylsalicylic Acid, with 10 cc. of sodium hydroxide T.S. for a few minutes, cool, and add 10 cc. of diluted sulphuric acid: a white precipitate of salicylic acid is produced, and the odor of acetic acid is perceptible. Filter, add to the filtrate 3 cc. of alcohol and 3 cc. of sulphuric acid, and warm; the odor of ethyl acetate becomes noticeable.

Tests for Purity—Ash: not more than 0.05 per cent.

A solution of 0.5 Gm. of Acetylsalicylic Acid in 10 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*).

A solution of 0.5 Gm. of the Acid, in 10 cc. of warm sodium carbonate T.S. is clear.

Shake 1 Gm. of Acetylsalicylic Acid with 20 cc. of distilled water and 1 cc. of nitric acid for one minute, and filter: five cc. portions of the filtrate yield no opalescence or turbidity at once on the addition of a few drops of silver nitrate T.S. (*chloride*) or barium chloride T.S. (*sulphate*).

Warm 1 Gm. of Acetylsalicylic Acid with 10 cc. of distilled water and 1 cc. of hydrochloric acid for two minutes, dilute with 40 cc. of distilled water, cool, and filter: the filtrate meets the requirements of the test for *heavy metals*, page 1519.

Dissolve 1 Gm. of Acetylsalicylic Acid in 5 cc. of alcohol, and allow the solution to evaporate spontaneously in a dish protected from dust: a white, crystalline residue is obtained (*coloring matter, resinous substances*).

Dissolve 0.1 Gm. of Acetylsalicylic Acid in 1 cc. of alcohol, dilute the solution with 48 cc. of cold distilled water, and add at once 1 cc. of a freshly prepared diluted ferric ammonium sulphate solution (made by adding 1 cc. of normal hydrochloric acid to 2 cc. of ferric ammonium sulphate T.S. and diluting with water to 100 cc.): the coloration, if any, produced in one-half minute, is not greater than that produced in a control test, using 1 cc. of a solution containing 0.1 Gm. of salicylic acid and 1 cc. of glacial acetic acid in 1 liter of water (*free salicylic acid*).

Assay—Add 50 cc. of half-normal sodium hydroxide to about 1.5 Gm. of Acetylsalicylic Acid, previously dried for three hours over sulphuric acid and accurately weighed, and boil gently for ten minutes. Titrate the excess of sodium hydroxide with half-normal sulphuric acid, using three drops of phenolphthalein T.S. as indicator. Make a blank test, using 50 cc. of half-normal sodium hydroxide, and from the comparisons make any necessary corrections. Each cc. of half-normal sodium hydroxide corresponds to 0.04503 Gm. of $C_6H_4.O(CH_3CO).COOH$.

This assay is explained on page 1454.

Preserve in well-closed containers.

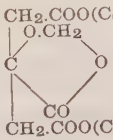
Uses—Acetylsalicylic acid is employed in rheumatic conditions, and especially as analgesics and antipyretics in colds, neuralgias, etc. The analgesic effects surpass those of sodium salicylate, with less danger of local irritation. It is used as a gargle in tonsillitis, five grains being dissolved in several ounces of water and used frequently.

The promiscuous use of acetylsalicylic acid (aspirin) by the laity, especially for the relief of headache, has frequently led to cases of rather severe poisoning, the chief symptoms being edema of the lips, tongue, eyelids, nose or of the entire face; also urticarial rashes, vertigo, nausea and sometimes cyanosis. Some individuals are especially susceptible to the effects of acetylsalicylic acid and these symptoms are usually ascribed to an idiosyncrasy.

Dose—From 0.3 to 1 Gm. (5 to 15 grains), repeated once in three hours until symptoms of salicylism (ringing in the ears, etc.) are noted. It may be administered in the form of a powder, wafers, or capsules. If prescribed as a powder, this may be administered by dissolving it in sweetened water, or by placing it on the tongue, and taking a swallow of water. The powder should be dispensed in wax paper. It is decomposed when dissolved in water and therefore only extemporaneously prepared aqueous solutions should be used.

Unofficial Salicylic Acid Compounds

Novaspirin, N. N. R.—*Salicitrin.*—Methylene-Citrylsalicylic Acid.



$CH_2.COO(C_6H_4.COOH)$
$O.CH_2$
C O
CO
$CH_2.COO(C_6H_4.COOH)$.—

A compound of anhydro-methylene-citric acid and salicylic acid.

Novaspirin is a grayish-white, odorless, crystalline powder, permanent in the air, having a faint acidulous taste. It is almost insoluble in water; soluble in alcohol; less soluble in ether or chloroform.

Actions and Uses—Similar to acetylsalicylic acid (see page 827), in doses of 15 grains (1 Gm.).

Ethyl Salicylate, N. N. R.—*Aethylis Salicylas,* Sal-ethyl—$C_6H_4.OH.C.O.O.(C_2H_5)$—The salicylic acid ester of ethyl alcohol analogous to methyl salicylate (oil of wintergreen).

A transparent, colorless, volatile liquid, possessing a pleasant characteristic odor and taste.

Actions and Uses—Ethyl salicylate has the same action as methyl salicylate, but is said to be less irritant and less toxic.

Dose—From 0.3 to 0.6 cc. (5 to 10 minims) three or four times a day.

Its specific gravity is 1.132 at 20° C. and it boils at from 230° to 232° C. It is insoluble in water, but soluble in alcohol.

Manufactured by Merck and Company, and Parke, Davis and Company.

Mesotan, N. N. R.—*Salmester*—$C_6H_4.OH.CO.O.(CH_2.O.CH_3)$—Methyl-oxymethyl salicylate, an ester of salicylic acid, analogous to methyl salicylate.

A clear, yellowish, faintly aromatic, oily fluid; specific gravity 1.2 at 15° C. and boiling at about 162° C. It is but slightly soluble in water, but readily soluble in the usual organic solvents and miscible with oils in all proportions.

It should be kept in a cool place and preserved dry in well-stoppered bottles.

Actions and Uses—Mesotan is an active counterirritant, used especially in rheumatic conditions, similarly to the local application of methyl salicylate. It is more irritant than the latter, and lacks its odor. It is absorbed from the skin, but its action is predominantly local, relieving pain and swelling. It is not an efficient means for producing the systemic actions of salicylates.

Dose—For application mesotan is diluted with 1 to 4 parts of olive oil or cottonseed oil, and painted over the affected area, usually twice daily. Friction should not be used, and dressings, if any are necessary, should be light and permeable. The site of application should be changed, if possible, after each treatment; or the area may be rested for two days after four days of treatment.

Distributed by The Winthrop Chemical Company. Manufactured by The Bayer Company.

Spirosal, N. N. R., 1925—*Monoglycol Salicylate*—Glysal—$C_6H_4OH.CO.O.(CH_2.CH_2.OH)$—The salicylic acid ester of monoglycol.

An almost odorless and colorless oily fluid, with a boiling point of from 169° to 170° C. at 12 mm. pressure. It is easily soluble in alcohol, ether, chloroform and benzol and soluble in about 110 parts of water and 8 parts of olive oil.

Actions and Uses—When spirosal is applied to the skin, about one-fifth to one-sixth of the amount used is absorbed. Usually it causes very little irritation even when rubbed in thoroughly.

Dose—It is used undiluted or mixed with from 2 to 3 parts of alcohol or in a mixture with olive oil, 1 to 8, or in ointments with equal parts by weight of petroleum or lard.

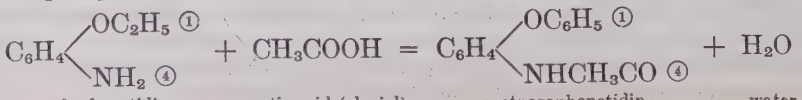
Distributed by The Winthrop Chemical Company. Manufactured by The Bayer Company.

ACETPHENETIDINUM. U. S. Acetphenetidin

[**Acetphen.**—PHENACETIN (PHENACETINUM)]

Monoacetyl para-amidophenetol [$C_6H_4(OC_2H_5).NH.CH_3CO$ 1:4 = 179.16].

Preparation—Acetphenetidin is made by treating paraphenetidin $C_6H_4(NH_2)OC_2H_5$ with glacial acetic acid, which introduces the acetyl group, and acetparaphenetidin ($C_6H_4(NHC_2H_3O)OC_2H_5$) is formed.



C_6H_4 (OC_2H_5 ①, NH_2 ④) + CH_3COOH = C_6H_4 (OC_6H_5 ①, $NHCH_3CO$ ④) + H_2O

paraphenetidin — acetic acid (glacial) — acetparaphenetidin — water

Description and Physical Properties—White, glistening, crystalline scales, or a fine, white, crystalline powder. It is odorless, has a slightly bitter taste, and is stable in the air.

One Gm. of Acetphenetidin is soluble in 1310 cc. of water, 15 cc. of alcohol, 14 cc. of chloroform and in about 130 cc. of ether, at 25° C. One Gm. is soluble in 82 cc. of boiling water and in 2.8 cc. of boiling alcohol.

Tests for Identity—Acetphenetidin melts between 134° and 135° C.

Boil about 0.1 Gm. of Acetphenetidin for one minute with 1 cc. of hydrochloric acid, dilute with 10 cc. of distilled water, cool, filter, and add a drop of potassium dichromate T.S. to the filtrate: a ruby-red color results.

Tests for Purity—Ash: not more than 0.05 per cent.

Shake about 1 Gm. of Acetphenetidin with 20 cc. of distilled water during two minutes, and filter: the filtrate is neutral to litmus paper.

A mixture of about 0.005 Gm. of Acetphenetidin and 1 cc. of nitric acid develops a yellow color which becomes darker on standing. A solution of 0.5 Gm. of Acetphenetidin in 5 cc. of sulphuric acid is only faintly yellow (*readily carbonizable substances*).

Boil 0.5 Gm. of Acetphenetidin with 10 cc. of distilled water for one minute, cool, filter, and add bromine T.S. to the filtrate, drop by drop, agitating after each addition until the solution remains permanently yellow: neither turbidity nor precipitation results (*acetanilid*).

A mixture of 0.3 Gm. of Acetphenetidin with 1 cc. of alcohol and one drop of tenth-normal iodine does not acquire a red tint when diluted with three times its volume of distilled water and boiled (*paraphenetidin*).

Uses—Acetphenetidin, or *phenacetin*, is a valuable antipyretic and analgesic; the absence of paraphenetidin in the product should be assured; the dose is from five to fifteen grains (0.3 to 1 Gm.).

ACETANILIDUM. U.S. Acetanilid

[**Acetanil.**—ACETANILIDE, ANTIFEBRIN, PHENYLACETAMIDE]

Monoacetyl aniline [$C_6H_5NH.CH_3CO = 135.12$].

Preparation—Acetanilid or *antifebrin* is made by the prolonged heating of a mixture of aniline and glacial acetic acid at the boiling point; the cooled, congealed residue is purified by sublimation or recrystallization.

The reaction is illustrated by the following equation:

$$\underset{\text{acetic acid (glacial)}}{CH_3COOH} + \underset{\text{aniline}}{C_6H_5NH_2} = \underset{\text{acetanilid}}{CH_3CONHC_6H_5} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—Colorless, shining, crystalline leaflets, or a white, crystalline powder. It is odorless, and is stable in the air.

One Gm. of Acetanilid is soluble in 190 cc. of water, 3.4 cc. of alcohol, 3.7 cc. of chloroform, 17 cc. of ether, 4 cc. of acetone, 47 cc. of benzene, and in about 5 cc. of glycerin, at 25° C. One Gm. is soluble in 20 cc. of boiling water and in 0.6 cc. of boiling alcohol. It is slightly soluble in petroleum benzin.

Tests for Identity—Acetanilid melts between 113° and 115° C.

Boil about 0.1 Gm. of Acetanilid with 5 cc. of sodium hydroxide T.S.: the characteristic odor of aniline becomes noticeable. Add 1 cc. of chloroform, and heat the mixture: the disagreeable odor of phenylisocyanide (a poisonous substance) is evolved.

Boil about 0.1 Gm. of Acetanilid for several minutes with 2 cc. of hydrochloric acid: a clear solution results, which, when mixed with 3 cc. of an aqueous solution of phenol (1 in 20) and 5 cc. of a filtered, saturated solution of chlorinated lime, acquires a brownish-red color which becomes deep blue upon supersaturation with ammonia water.

Bromine T.S. produces a white, crystalline precipitate in a saturated aqueous solution of Acetanilid.

Tests for Purity—Ash: not more than 0.05 per cent.

Shake 1 Gm. of Acetanilid with 20 cc. of distilled water for two minutes and filter: the filtrate is neutral to litmus paper. Add five drops of ferric chloride T.S. to 5 cc. of the filtrate: the color does not differ from that produced by adding five drops of ferric chloride T.S. to 5 cc. of distilled water (*aniline salts*).

The solution of 0.5 Gm. of Acetanilid in 5 cc. of sulphuric acid is colorless or only faintly yellow (*readily carbonizable substances*).

N. F. Preparation—Pulvis Acetanilidi Compositus.

Uses—Acetanilid is an antipyretic and analgesic. When in very fine powder it is occasionally used as an antiseptic application to wounds. It is largely

employed in popular headache remedies, but should always be used with caution as an overdose is dangerous. The dose is from three to ten grains (0.2 to 0.6 Gm.).

Unofficial Preparation

Ammoniated Acetanilid — A mixture containing acetanilid 25 parts; sodium bicarbonate 5 parts; ammonium carbonate 10 parts and milk-sugar 60 parts. It has been recommended in place of acetanilid, being less depressing in action.

ANTIPYRINA. U. S. Antipyrine

[**Antipyr.**—PHENAZONE, PHENYL-DIMETHYL-PYRAZOLON]

Phenyldimethyl pyrazolon [$C_3HON_2(CH_3)_2.C_6H_5 = 188.17$).

Preserve it in well-closed containers.

Preparation—Antipyrine is made by Knorr's process by acting on phenyl-hydrazine with aceto-acetic ether when phenylmethyl pyrazolon is formed; this is methylated by treatment with methyl-iodide, resulting in the formation of phenyldimethyl pyrazolon or antipyrine.

Description and Physical Properties—Colorless crystals, or a white, crystalline powder. It is odorless, and has a slightly bitter taste.

One Gm. of Antipyrine is soluble in less than 1 cc. of water, 1.3 cc. of alcohol, 1 cc. of chloroform, and in 43 cc. of ether, at 25° C.

Tests for Identity—Antipyrine melts between 111° and 113° C.

The addition of tannic acid T.S. to an aqueous solution of Antipyrine produces an abundant white precipitate.

Mix 0.1 Gm. of sodium nitrite and 12 cc. of an aqueous solution of Antipyrine (1 in 100): a nearly colorless liquid is obtained, which, upon the addition of 1 cc. of diluted sulphuric acid, develops a deep green color.

One drop of ferric chloride T.S. added to 2 cc. of a dilute aqueous solution of Antipyrine (1 in 1000) produces a deep red color, which, upon the addition of ten drops of sulphuric acid, is changed to light yellow.

Tests for Purity—Its aqueous solution (1 in 20) is neutral to litmus paper.

Ash: not more than 0.1 per cent.

Antipyrine is completely soluble in its own weight of cold distilled water, the solution being colorless or not more than slightly yellow when viewed transversely in a tube having a diameter of about 20 mm.

An aqueous solution of Antipyrine meets the requirements of the test for *heavy metals*, page 1519.

Uses—Antipyrine is an antipyretic, analgesic, and antirheumatic. It is employed as a local remedy in nose and throat diseases. The dose is five grains (0.3 Gm.).

AMIDOPYRINA. U. S. Amidopyrine

[**Amidopyrin.**—PYRAMIDON]

Dimethylamino-antipyrine [$C_3ON_3(CH_3)_4.C_6H_5$].

Dimethylamino-phenyl-dimethyl-pyrazolon, differing from antipyrine, $C_{11}H_{12}N_2O$, in that a dimethylamino group, $N(CH_3)_2$, has replaced a hydrogen atom of the pyrazolon nucleus.

Description and Physical Properties—Colorless or white, small crystals, or a white, crystalline powder. It is odorless, and is stable in the air.

One Gm. of Amidopyrine is soluble in 18 cc. of water, 1.5 cc. of alcohol, 12 cc. of benzene, 1 cc. of chloroform, and in 13 cc. of ether, at 25° C.

Tests for Identity—Amidopyrine melts between 107° and 109° C.

An aqueous solution of Amidopyrine (1 in 25) is slightly alkaline to litmus paper.

To 5 cc. of an aqueous solution of Amidopyrine (1 in 25) add three drops of diluted hydrochloric acid and 1 cc. of ferric chloride T.S.: a bluish-violet color is produced. On the subsequent addition of a few cc. of diluted sulphuric acid, the color changes to violet-red.

The addition of five drops of silver nitrate T.S. to 5 cc. of an aqueous solution of Amidopyrine (1 in 25) produces an intensely violet color (other oxidizing substances yield the same color). On allowing the mixture to stand, a grayish-black precipitate of metallic silver is deposited.

To a solution of about 0.02 Gm. of Amidopyrine in 5 cc. of distilled water, add two drops of sulphuric acid and two drops of a 10 per cent solution of sodium nitrite: a transient blue color is produced which disappears quickly, the liquid remaining colorless (the appearance of a green color indicates *antipyrine*).

An aqueous solution of Amidopyrine (1 in 25) added to a freshly prepared solution of potassium ferricyanide, containing a little ferric chloride, produces at once a dark blue color or precipitate (difference from *antipyrine*).

Tests for Purity—Ash, not more than 0.1 per cent.

A solution of 0.1 Gm. of Amidopyrine in 1 cc. of sulphuric acid is colorless (*readily carbonizable substances*).

Its aqueous solution (1 in 25) meets the requirements of the test for *heavy metals*, page 1519.

The addition of a few drops of silver nitrate T.S. to 5 cc. of an aqueous solution of Amidopyrine (1 in 25), previously acidulated with a few drops of diluted nitric acid, produces no turbidity at once (*chloride*).

Uses—Amidopyrine acts as an antipyretic and anodyne, like antipyrine, but is effective in smaller doses. The action, while somewhat slower at the beginning, is more lasting. It is claimed to be comparatively free from harmful influences on the blood, heart or kidneys. It is said to be useful, particularly in the chronic fevers of tuberculosis, as well as in the acute febrile conditions incident to typhoid fever, erysipelas and pneumonia.

Dose—From 5 to 6 grains (0.3 to 0.4 Gm.), most conveniently in the form of tablets, a single dose usually suffices for twenty-four hours. The title pyramidon is trade marked.

Unofficial Compounds

Apinal, N. N. R.

Obtained in the destructive distillation of the wood of *Pinus palustris* and *Pinus australis*. Claimed to be mainly levomenthone. Antiseptic, germicidal, local anesthetic and expectorant. Dose, 5 to 15 min. (0.3 to 1 cc.) on sugar. It may be applied directly to wounds

Benzene, Medicinal, N. N. R.—C_6H_6
Medicinal benzol
Crystallizable benzol

A liquid consisting almost entirely of benzene, prepared by fractional distillation. A colorless, mobile liquid, having a strong characteristic odor. Insoluble in water but soluble in 90 per cent alcohol. It has been used in the treatment of leukemia. Use with caution. Dose, 8 to 15 min. (0.5 to 1 cc.) four times a day. May be administered in capsules or as an emulsion

CHAPTER LIX

BENZOIC ACID—ITS COMPOUNDS AND DERIVATIVES

FORMERLY benzoic acid was considered under benzoin, but since it is now almost entirely produced synthetically and, especially, since many important compounds of benzoic acid are now employed in medicine, a special chapter has been provided for their consideration.

Tests for Benzoates

Benzoates—In neutral solutions, benzoates yield a salmon-colored precipitate with ferric chloride T.S. In moderately concentrated aqueous solutions, benzoates yield a precipitate of benzoic acid upon acidulation with diluted sulphuric acid. This precipitate is readily soluble in ether.

ACIDUM BENZOICUM. U.S. Benzoic Acid
[Acid. Benz.]

Benzoic Acid, dried at 100° C. for two hours, contains not less than 99.3 per cent of $C_6H_5.COOH$ (122.08).

Preparation—Benzoic acid is found naturally in benzoin, balsam of tolu, balsam of Peru, storax, and other resinous substances. It may be obtained from these by sublimation as described on page 146; but, owing to the small yield afforded in this way, commercial benzoic acid is made artificially in several ways:

1. It was formerly prepared from the urine of cattle, by mixing it with lime in excess, evaporating and decomposing the lime hippurate with hydrochloric acid. The separated hippuric acid, after purification with animal charcoal was again treated with hydrochloric acid, when benzoic acid and *glycocine* are produced, the hydrochloric acid not being decomposed. This process has been replaced by one of the following.

2. Benzoic acid may be made from *naphthalene*, $C_{10}H_8$, which, on treatment with nitric acid, yields *phthalic acid*, this, when heated with excess of calcium hydroxide, yields calcium benzoate and carbonate. The calcium benzoate is treated with hydrochloric acid and the benzoic acid is precipitated.

3. Benzoic acid is also largely made from toluene, C_7H_8, a coal-tar hydrocarbon. Benzotrichloride is first formed, and this when heated with water in close vessels yields benzoic acid.

$$\underset{\text{benzotrichloride}}{C_6H_5.CCl_3} + \underset{\text{water}}{2H_2O} = \underset{\text{benzoic acid}}{C_6H_5.COOH} + \underset{\text{hydrochloric acid}}{3HCl}$$

Description and Physical Properties—Lustrous scales or friable needles. The synthetic Acid is white and odorless, or it may have a slight odor of benzaldehyde. The natural Acid is white or yellowish, acquiring a darker color on exposure to light, and has a slight odor of benzoin. Benzoic Acid is somewhat volatile at moderately warm temperatures, and freely volatile with steam.

One Gm. of Benzoic Acid is soluble in 275 cc. of water, 2.3 cc. of alcohol, 4.5 cc. of chloroform, 3 cc. of ether, 10 cc. of benzene, 30 cc. of carbon disulphide or carbon tetrachloride, and in 23 cc. of oil of turpentine, at 25° C. One Gm. is soluble in 18 cc. of boiling water, and in 1.5 cc. of boiling alcohol. It is soluble in fixed or volatile oils and is sparingly soluble in petroleum benzin.

Tests for Identity—Benzoic Acid melts between 120° and 122° C.

Benzoic Acid responds to the reactions for benzoates, page 832.

Tests for Purity—Ash: not more than 0.05 per cent.

A solution of 0.1 Gm. of the synthetic Acid in 2 cc. of sulphuric acid does not become darker than light yellow when warmed for five minutes at 50° C. The color produced by the Acid from benzoin tested in the same manner does not become darker than light brown (*readily carbonizable substances*).

Dissolve 0.3 Gm. of the Acid in 15 cc. of hot water, and add to the solution 2 cc. of tenth-normal potassium permanganate: the odor of benzaldehyde is not perceptible (*cinnamic acid*).

Mix 0.5 Gm. of Benzoic Acid and 0.7 Gm. of calcium carbonate with a little distilled water in a crucible, dry the mixture, and incinerate it at a low red heat. Dissolve the residue in 20 cc. of diluted nitric acid, filter, wash the filter and insoluble residue with 15 cc. of distilled water, add to the filtrate 0.5 cc. of tenth-normal silver nitrate, and dilute with distilled water to 50 cc. Dis-

solve 0.7 Gm. of the same calcium carbonate in 20 cc. of diluted nitric acid, filter if necessary, add 0.5 cc. of tenth-normal silver nitrate, and dilute with distilled water to 50 cc. Add to this solution fiftieth-normal hydrochloric acid, drop by drop, mixing well after each addition, until the turbidity matches that in the test with the Benzoic Acid. If the synthetic Acid is tested, not more than 0.6 cc. of fiftieth-normal hydrochloric acid is required in the control test to match the turbidity and, if the natural Acid is tested, not more than 0.3 cc. of fiftieth-normal hydrochloric acid is required (*chlorinated compounds*).

Assay—Dry about 1 Gm. of Benzoic Acid at 100° C. for two hours, and dissolve 0.5 Gm. of the dried Acid, accurately weighed, in 25 cc. of diluted alcohol, which has previously been neutralized with tenth-normal sodium hydroxide, using three drops of phenolphthalein T.S. as indicator. Titrate this solution with tenth-normal barium hydroxide until the pink color is restored. From the number of cc. of tenth-normal barium hydroxide consumed, subtract one-fifth of the volume of fiftieth-normal hydrochloric acid used in the test for chlorinated compounds. Each cc. of tenth normal barium hydroxide corresponds to 0.01221 Gm. of $C_6H_5.COOH$.

This assay is explained on page 1456.

Preserve in well-closed containers, in a cool place, protected from light.

U. S. P. Preparation—Tinctura Opii Camphorata.

N. F. Preparation—Nebula Aromatica.

Uses—This acid is useful in forming *benzoates*, a class of salts which have been employed frequently during the last few years. It is stimulant, expectorant, and irritant to the mucous membranes. The commercial nomenclature of benzoic acid is both interesting and important; the natural acid, sublimed from the drug is known as *"English Benzoic Acid"* also as *Flowers of Benzoin* or *Flowers of Benjamin.*

The synthetic benzoic acid is known as *"German Benzoic Acid"*.

Benzoic acid is an active germicide but is used in medicine chiefly in the form of its salts. It is sometimes used in mouth washes or in lozenges for its stimulating and antiseptic effect. Dose, fifteen grains (1 Gm.), administered in thick mucilage or syrup.

GLUSIDUM. U. S. Gluside

[**Glusid.**—Benzosulphinidum U. S. P. IX, Saccharin]

The anhydride [$C_6H_4.CO.SO_2.NH$ 1:2 = 183.14] of ortho-sulphamide-benzoic acid.

Saccharin, as it is commercially named, is made from the coal-tar product, toluene, by converting it into toluene-sulphonic chloride. This is treated with ammonia, whereby the sulphamide is formed, which by oxidation is converted into the sulphinide, saccharin being the anhydride of ortho-sulphamide-benzoic acid. The soluble form, which is a sodium salt, is also official (see page 834).

Description and Physical Properties—White crystals, or a white, crystalline powder. It is odorless, or has a faint, aromatic odor. Gluside in aqueous solution is from 300 to 500 times sweeter than sucrose.

One Gm. of Gluside is soluble in 290 cc. of water and in 31 cc. of alcohol, at 25° C. One Gm. is soluble in about 25 cc. of boiling water. It is slightly soluble in chloroform and in ether, and is easily dissolved by ammonia water, by solutions of alkali hydroxides, and by solutions of alkali bicarbonates with the evolution of carbon dioxide.

Tests for Identity—The melting point of Gluside is not below 222° C. Pure Gluside melts at about 228° C.

A saturated aqueous solution of Gluside is acid to litmus paper.

Dissolve about 0.1 Gm. of Gluside in 5 cc. of an aqueous solution of sodium hydroxide (1 in 10), evaporate the solution to dryness, and gently fuse the residue over a small flame until ammonia is no longer evolved. Allow the residue to cool, dissolve in 20 cc. of distilled water, neutralize the solution with diluted hydrochloric acid, and filter; the addition of a drop of ferric chloride T.S. to the filtrate produces a violet color.

Mix about 0.02 Gm. of Gluside with about twice its weight of resorcinol, add ten drops of sulphuric acid, and heat the mixture over a small flame until it acquires a dark green color. Allow it to cool, add 10 cc. of distilled water, and an excess of sodium hydroxide T.S.: a fluorescent, green liquid results.

Tests for Purity—Ash: not more than 0.5 per cent.

A solution of 0.2 Gm. of Gluside in 10 cc. of sulphuric acid, kept at a temperature of from 48° C. to 50° C. on a water bath, develops no darker color than light brown within ten minutes (*readily carbonizable substances*).

A solution of 0.2 Gm. of Gluside in 5 cc. of sodium hydroxide T.S. is clear, and, when mixed with 5 cc. alkaline cupric tartrate T.S. does not deposit cuprous oxide on heating (*glucose, lactose*).

Add ferric chloride T.S, drop by drop, to 10 cc. of a hot, saturated aqueous solution of Gluside: no precipitate or violet color appears (*benzoic or salicylic acid*).

No odor of ammonia is noticeable on warming 0.5 Gm. of Gluside with about 1 Gm. of magnesium oxide and 10 cc. of distilled water (*ammonium compounds*).

U. S. P. Preparation—Fluidextractum Cascaræ Sagradæ Aromaticum.

N. F. Preparations—Elixir Terpini Hydratis et Creosoti Compositum; Lavatio Ori; Oleum Ricini Aromaticum; Tabellæ Phenolphthaleini; Tabellæ Santonini; Tabellæ Santonini Compositæ.

Uses—Benzosulphinide is used for sweetening, but the Food and Drugs Act and most State food laws prohibit its use in foods and beverages. It has many times the sweetening power of sugar.

Average dose—As a sweetening agent, for diabetics, Gluside is used in the proportion of about 1 to 10,000 (Metric, 0.1 Gm. per liter—Apothecaries, $\frac{1}{20}$ grain per ounce) or, in place of an ordinary "lump" of sucrose, one-half grain (0.03 Gm.).

GLUSIDUM SOLUBILE. U. S. Soluble Gluside

[**Glusid. Sol.**—Sodii Benzosulphinidum U. S. P. IX, Soluble Saccharin]

The sodium salt [$NaC_7H_4O_3NS + 2H_2O = 241.1$] of benzosulphinide. Preserve it in well-closed containers.

Preparation—It is prepared by neutralizing ortho-sulphamidebenzoic acid or "saccharin" with sodium bicarbonate.

$$C_6H_4.CO.SO_2NNa.2H_2O$$

Description and Physical Properties—Colorless crystals or a white, crystalline powder. It is odorless or has a faint, aromatic odor, and an intensely sweet taste even in dilute solutions, being from 300 to 500 times sweeter than sucrose. It is somewhat efflorescent.

One Gm. of Soluble Gluside is soluble in 1.2 cc. of water, and about 50 cc. of alcohol, at 25° C.

Tests for Identity—Soluble Gluside responds to the identity tests with ferric chloride and with resorcinol under *Glusidum*.

When Soluble Gluside is incinerated, a residue remains consisting chiefly of sodium sulphate, which imparts a yellowish color to a non-luminous flame.

On mixing 10 cc. of its aqueous solution (1 in 10) with 1 cc. of hydrochloric acid, a crystalline precipitate of gluside is produced.

Tests for Purity—An aqueous solution of Soluble Gluside (1 in 10) is neutral or only slightly alkaline to litmus paper, but produces no red color with phenolphthalein T.S.

Add three drops of ferric chloride T.S. to 10 cc. of an aqueous solution of Soluble Gluside (1 in 20), previously acidulated with five drops of acetic acid: no precipitate or violet color is produced (*benzoate or salicylate*).

Soluble Gluside complies with the tests for *ammonium compounds, readily carbonizable substances, and for glucose and lactose*, under *Glusidum*.

Uses—It is used as a sweetening substance, chiefly by persons who are suffering from diabetes or other serious complaints in which sugar is contraindicated. The sodium salt is more readily soluble than gluside but does not possess quite an equal sweetening power, gluside is approximately five hundred times sweeter than sugar, and the sodium salt about four hundred times. Its use as a sweetening agent in beverages and food is prohibited by the Food and Drugs Act and by many State laws.

Average dose—As a sweetening agent, in diabetes, etc., Soluble Gluside is used in the proportion of about 1 to 10,000 (Metric, 0.1 Gm. per liter—Apothecaries, $\frac{1}{20}$ grain per ounce) or, in place of an ordinary "lump" of sucrose, one-half grain (0.03 Gm.).

ÆTHYLIS AMINOBENZOAS. U. S. Ethyl Aminobenzoate

[**Æthyl. Aminobenz.**—Benzocaine, Anesthesin]

The ethyl ester [$C_6H_4NH_2COO(C_2H_5)1:4 = 165.14$] of 4-aminobenzoic acid.

This is one of a group of synthetic products based upon the discovery that the local anesthetic action of cocaine is due to the radicle of benzoic acid in

combination with a nitrogen-containing basic group. Among the preparations of this type now in use are benzocaine, orthoform, stocaine, procaine, alypin, butesin, etc. Those which are slowly absorbed (benzocaine, orthoform, and butesin) are suitable for a dressing to painful wounds, etc. The others are employed hypodermatically for immediate anesthesia (see uses below).

Description and Physical Properties—Small, white or colorless crystals, or a white, crystalline powder. It is odorless and is stable in the air.

One Gm. of Ethyl Aminobenzoate is soluble in about 2500 cc. of water, 5 cc. of alcohol, 2 cc. of chloroform, 4 cc. of ether, and in from 30 to 50 cc. of expressed oil of almond or olive oil, at 25° C. It is soluble in dilute acids.

Tests for Identity—Ethyl Aminobenzoate melts between 88° and 90° C.

When boiled with alkali hydroxides, alcohol is liberated.

Dissolve about 0.02 Gm. of Ethyl Aminobenzoate in 10 cc. of distilled water with the aid of a few drops of diluted hydrochloric acid, and add to the solution five drops of a 10 per cent sodium nitrite solution, followed by 2 cc. of a solution of 0.1 Gm. of betanaphthol in 5 cc. of sodium hydroxide T.S.: an orange-red precipitate is produced.

Its aqueous solution (1 in 50), prepared with the aid of a slight excess of diluted hydrochloric acid, yields a precipitate with iodine T.S., and instantly reduces potassium permanganate T.S.

Tests for Purity—Ash: not more than 0.1 per cent.

A solution of 0.1 Gm. of Ethyl Aminobenzoate in 1 cc. of sulphuric acid is colorless (*readily carbonizable substances*).

Dissolve 1 Gm. of Ethyl Aminobenzoate in 10 cc. of neutral alcohol: a clear solution results. Dilute this solution with 10 cc. of distilled water, add two drops of phenolphthalein T.S. and one drop of tenth-normal sodium hydroxide: a red color is produced (*free acid*).

The addition of a few drops of silver nitrate T.S. to a solution of 0.2 Gm. of Ethyl Aminobenzoate in 5 cc. of alcohol, previously acidulated with a few drops of diluted nitric acid, produces no immediate turbidity (*chloride*).

An aqueous solution of Ethyl Aminobenzoate (1 in 20) prepared with the aid of just sufficient hydrochloric acid meets the requirements of the test for *heavy metals*, page 1519.

Heat a crucible to redness, and add, in small portions, an intimate mixture of 0.2 Gm. of Ethyl Aminobenzoate, about 0.5 Gm. of potassium nitrate, and about 0.3 Gm. of anhydrous sodium carbonate. Maintain a red heat until the reaction ceases, then boil the cooled residue for five minutes with 10 cc. of diluted sulphuric acid, filter, and wash the undissolved residue with 10 cc. of distilled water. Evaporate the filtrate and washings until sulphuric acid vapors begin to evolve: the residue, dissolved in 5 cc. of distilled water, meets the requirements of the test for *arsenic*, page 1512.

Uses—The slight solubility of benzocaine renders it unsuitable for injection, but the slow absorption renders it safer than other anesthetics, especially for ulcers, wounds, and mucous surfaces. The anesthesia is usually not so complete as with the soluble local anesthetics but is more lasting. Orthoform and benzocaine (see page 839) are about equally effective through intact mucous membranes; butesin (see page 839) is claimed to be more effective than benzocaine. They are practically nonirritant and non-toxic.

They are used for painful wounds, ulcers, etc., of the skin and accessible mucous membranes; for instance, after dental operations. They have all been used to relieve or control the pain of gastric ulcer or cancer and other gastralgias, but here their efficiency is doubtful.

Dose—Internally, from 5 to 8 grains (0.3 to 0.5 Gm.). Externally, it is applied as a dusting powder, either pure or diluted. It may be applied in ointment or in the form of suppositories.

PROCAINÆ HYDROCHLORIDUM. U. S. Procaine Hydrochloride [Procain. Hydrochl.]

Para-aminobenzoyl-diethylaminoethanol hydrochloride $[NH_2(C_6H_4CO)OC_2H_4N(C_2H_5)_2.HCl = 272.71]$.

Description and Physical Properties—Small, colorless crystals, or a white, crystalline powder. It is odorless, and is stable in the air.

One Gm. of Procaine Hydrochloride is soluble in 0.6 cc. of water and in 30 cc. of alcohol, at 25° C. It is slightly soluble in chloroform, and almost insoluble in ether.

Tests for Identity—Procaine Hydrochloride melts between 153° and 156° C.

An aqueous solution of Procaine Hydrochloride (1 in 10) yields precipitates with gold chloride T.S., iodine T.S., mercuric potassium iodide T.S. and picric acid T.S.

An aqueous solution of Procaine Hydrochloride (1 in 10) remains unchanged upon the addition of a solution of sodium bicarbonate, but with sodium hydroxide T.S. or sodium carbonate T.S., a colorless, oily precipitate is produced, which becomes crystalline on standing.

Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate insoluble in nitric acid, but soluble in ammonia water.

Dissolve 0.1 Gm. of Procaine Hydrochloride in 5 cc. of distilled water, add two drops each of hydrochloric acid and solution of sodium nitrite (1 in 10), and then a solution of 0.2 Gm. of beta-naphthol in a mixture of 3 cc. of sodium hydroxide T.S. and 7 cc. of distilled water. A scarlet-red precipitate is produced (*difference from phenacaine* which yields a white precipitate).

To a solution of 0.1 Gm. of Procaine Hydrochloride in 5 cc. of distilled water add three drops of diluted sulphuric acid, followed by five drops of potassium permanganate T.S.: the violet color of the latter is immediately discharged (*difference from cocaine hydrochloride*).

Tests for Purity—Its aqueous solution (1 in 20) is neutral to litmus paper.

The ash from 0.5 Gm. is negligible.

A solution of 0.1 Gm. of Procaine Hydrochloride in 1 cc. of sulphuric acid is colorless or nearly colorless (*readily carbonizable substances*).

An aqueous solution of Procaine Hydrochloride meets the requirements of the test for *heavy metals*, page 1519.

Uses—Procaine hydrochloride is a local anesthetic similar in action to cocaine, but less toxic than cocaine and most other cocaine substitutes. When injected subcutaneously it exerts a prompt and powerful anesthetic action, but the effect is not sustained. This may be remedied by the simultaneous injection of epinephrine. Procaine hydrochloride is nonirritant. It is relatively ineffective when applied to intact mucous membranes.

Dose—For infiltration anesthesia, solutions of 0.25 Gm. (4 grains) procaine hydrochloride in 100 or 50 cc. (3.2 or 1.6 ounces) physiological solution of sodium chloride, with 0.3 or 0.6 cc. (5 or 10 minims) of epinephrine solution (1 in 1000); for instillations and injections, solutions of 0.1 Gm. (1½ grains) procaine in 10 or 5 cc. (160 or 80 minims) physiological solution of sodium chloride, with or without 0.6 cc. (10 minims) of epinephrine solution (1 in 1000). In ophthalmology, 1 to 5 or even up to 10 per cent solution; in rhinolaryngology, 5 to 20 per cent solutions are recommended, with the addition of 0.4 to 0.5 cc. (6 to 8 minims) of epinephrine solution (1 in 1000) to each 10 cc. (160 minims). Internally, owing to its feeble toxicity, it may be given in doses up to 0.5 Gm. (8 grains) to adults.

LIQUOR PROCAINÆ HYDROCHLORIDI. N.F. Solution of Procaine Hydrochloride

[Liq. Procain. Hydroch.—Dental Anaesthetic Solution]

	Metric	Alternative
Procaine Hydrochloride	**2.00 Gm.**	146 gr.
Sodium Chloride	**0.92 Gm.**	67 gr.
Thymol	**0.02 Gm.**	1.5 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**100 cc.**	1 pint

Dissolve the procaine hydrochloride and sodium chloride in about 98 cc. [15½ fl.oz.] of sterilized distilled water, and boil the solution for ten minutes under sterile conditions. Then cool, dissolve the thymol in the solution and add sufficient sterilized, distilled water to make the product measure 100 cc. [1 pint].

Solution of Procaine Hydrochloride is a clear, colorless, almost odorless liquid, neutral to litmus paper, and having a slightly saline taste.

One cc. portions of this solution show marked precipitation with iodine T.S., mercuric potassium iodide T.S., and picric acid T.S.

Silver nitrate T.S. gives a white precipitate with the Solution, soluble in an excess of ammonia T.S.

To 5 cc. of the Solution add two drops each of hydrochloric acid and sodium nitrite solution (1 in 10); then 2 Gm. of betanaphthol in 3 cc. of sodium hydroxide T.S. and 7 cc. of water. A bright red precipitate should be produced (*difference from phenacaine*).

Preserve the solution in bottles of resistant glass.

To each cc. of this Solution add 0.05 cc. Solution of Epinephrine Hydrochloride just before employing hypodermatically.

Uses—(See Procainæ Hydrochloridum, above).

Unofficial Compounds of Benzoic Acid

Alypin, N. N. R.—The hydrochloride of 2-benzoxy-2-dimethyl-amino-methyl-1-dimethyl-amino-butane—$CH_3.CH_2.C(C_6H_5COO)\ [CH_2N(CH_3)_2].CH_2N : (CH_3)_2.HCl$.

A white, crystalline powder; odorless; taste bitter, hygroscopic. It is very soluble in water; freely soluble in alcohol and chloroform; insoluble in ether. Its aqueous solutions are neutral and are not rendered turbid on the addition of sodium bicarbonate solution in moderate quantities. Its aqueous solution may be sterilized by boiling for a period not exceeding five minutes without decomposition. Two and four per cent aqueous solutions are quite stable, but weaker solutions are likely to become moldy. It should be protected from the air in well-stoppered containers.

Uses—Alypin is a local anesthetic, claimed to be equal to cocaine, but is not a mydriatic. It is said to be less toxic than cocaine, but the evidence is rather conflicting.

Dose—Alypin is used in solutions the strength of which is about the same as that of cocaine hydrochloride. In ophthalmology, 2 to 4 per cent; in rhinolaryngology, 5 to 10 per cent; in urology, 1 to 4 per cent; in minor surgery, ½ to 2 per cent; in dentistry, 2 per cent.

Alypin solutions may be sterilized by boiling the required amount of water for ten minutes in a test tube stoppered with cotton; the drug is then added and the boiling continued over a small flame for another minute. Solutions should be freshly prepared. Epinephrine preparations may be added when a vasoconstrictor effect is desired.

Distributed by The Winthrop Chemical Company, Inc.

Apothesine, N. N. R.—γ-diethylaminopropyl cinnamate hydrochloride—$(C_2H_5)_2N.CH_2.CH_2CH_2.COO.CH : CH.C_6H_5HCl$. The hydrochloride of a condensation product prepared by the action of cinnamoyl chloride on γ-diethylaminopropyl-alcohol.

In white masses which are composed of small, white crystals; practically odorless; faintly bitter, but producing a sense of numbness of the tongue; permanent in the air. It is soluble in water and alcohol; slightly soluble in acetone or ether. Its aqueous solution is neutral to litmus paper. The solution is stable.

Uses—Apothesine is a local anesthetic of the procaine rather than the cocaine type, that is, it belongs to that type which while effective for injection anesthesia (especially when combined with epinephrine), is relatively inefficient when applied to mucous membranes. It is rather slower in action than procaine. Its absolute toxicity is less than that of cocaine (as 20 to 15) but about twice that of procaine as (20 is to 40). It is efficient and generally safe for injection. Apothesine solutions are not injured by boiling.

Dose—As a local anesthetic 0.5 to 2 per cent solution generally with epinephrine in sterile water or physiologic solution of sodium chloride. For spinal anesthesia 2 cc. of a 4 per cent solution. For oral administration 0.03 Gm. repeated at half hour intervals.

Manufactured by Parke, Davis and Company.

Benzyl Alcohol, N. N. R—*Alcohol Benzylicum*—Phenmethylol—$C_6H_5.CH_2OH$—An aromatic alcohol occurring as an ester in tolu and other balsams; the product on the market is produced synthetically.

A colorless liquid with a faint aromatic odor, and a sharp burning taste. When placed on the tongue, it produces numbness, even if only a small quantity is used. It is soluble, 1 cc. in 25 cc. of water, and miscible in all proportions with alcohol, ether, and chloroform. One volume of benzyl alcohol should dissolve in 1.5 volumes of 50 per cent alcohol.

Uses—Benzyl alcohol is used as a local anesthetic by injection and by application to mucous membranes. It is practically nonirritant and non-toxic in the ordinary concentrations and doses.

Dose—Usually used in the form of a 1 to 4 per cent solution in water or physiological solution of sodium chloride. Such solutions may be sterilized by boiling, without danger of decomposition. Pure benzyl alcohol is markedly antiseptic.

Benzyl Benzoate—*Benzyl Benzoas*—$C_6H_5COO.C_6H_5CH_2$—The benzyl alcohol ester of benzoic acid. It contains not less than 95 per cent benzyl benzoate.

A colorless oily liquid above about 20° C. It is odorless, or has a faint aromatic odor, and a sharp burning taste. It is insoluble in water or glycerin but miscible in all proportions with alcohol, chloroform and ether.

Benzyl benzoate boils at 340° to 350° C. with partial decomposition. When ignited it burns with a very smoky flame. Benzyl Benzoate is neutral to litmus paper. Specific gravity 1.09 to 1.13 at 15° C., 1.083 to 1.122 at 25° C.

One of the commercial preparations consists of a solution of 20 Gm. of benzyl benzoate in 78 Gm. of ethyl alcohol to which is added 2 Gm. of powdered castile soap as an emulsifying agent.

Uses—Benzyl Benzoate lowers the tone of unstriped muscle, and has been suggested as a remedy against renal, biliary, uterine, and intestinal colic and other spasms of smooth muscle, including angiospasm. Its clinical use is still in the experimental stage.

Benzyl Benzoate is sometimes administered in capsules, usually mixed with an equal quantity of a fixed oil.

Dose—5 to 7 minims (0.3 to 0.5 cc.).

The following formulas have been suggested for its administration.

Elixir Benzyl Benzoate

Benzyl Benzoate	200 cc.
Glucide Benzosulphinide	5.0 cc.
Oil of Bitter Almond	1.5 cc.
Oil of Sweet Orange Peel	1.0 cc.
Glycerin	90.0 cc.
Alcohol, *a sufficient quantity,*	
To make	1000 cc.

Mix the benzyl benzoate with the alcohol and when solution is effected, add the glucide, then the oils and lastly, slowly add the glycerin.

Emulsion Benzyl Benzoate

Benzyl Benzoate	200 cc.
Olive Oil	60 cc.
Oil of Cinnamon	5 cc.
Oil of Clove	5 cc.
Oil of Nutmeg	5 cc.
Acacia	100 Gm.
Syrup	120 cc.
Distilled Water, *a sufficient quantity,*	
To make	1000 cc.

Mix the benzyl benzoate with the oils, add the acacia in granular form, emulsify with 100 cc. of water, and then add the syrup and enough water to make the product measure 1000 cc.

Butyn, N. N. R.—Paraaminobenzoyl-gammadinormalbutylamino-propanol sulphate; γ-dibutylamino-propyl-*p*-aminobenzoate-*N*-sulphate—$[NH_2.C_6H_4.COO(CH_2)_3.N(C_4H_9)_2]_2.H_2SO_4$. The normal sulphate of a base resembling the base of procaine (paraaminobenzoyl-diethylaminoethanol); but it differs in that butyn possesses a butyl group in place of the ethyl group of procaine base, and a propanol group in place of the ethanol group.

A colorless, odorless solid which rapidly produces a sense of numbness when placed upon the tongue. It melts at from 98° to 100° C.

Butyn is soluble in less than its own weight of water at 20° C. It dissolves slowly in cold water, but rapidly in hot water. It is very soluble in warm alcohol and in acetone, from which it does not readily separate on cooling. It is slightly soluble in chloroform, and insoluble in ether.

Uses—Butyn is a local anesthetic proposed as a substitute for cocaine, particularly in surface anesthesia, as for the eye, nose and throat. It has the special advantage of acting through intact mucosæ almost as effectively as cocaine. On the normal human eye, a 0.5 per cent solution of butyn is less effective than a 1 per cent solution of phenacaine (holocaine), but more efficient than a 1 per cent solution of cocaine or a 1 per cent solution of eucaine. Butyn solutions are nonirritant.

Dose—For ophthalmologic work, butyn is generally used in 2 per cent solutions. A single application produces, within one minute, an anesthesia sufficient to permit the removal of superficially placed foreign bodies, the application of irritant astringents and the use of the tonometer. Four instillations, three minutes apart, permit operative work within five minutes after the last instillation, producing an anesthesia sufficient to perform all of the commoner operations on the eye. In nose and throat work, solutions of from 2 to 5 per cent are usually employed. Butyn solutions may be sterilized by boiling.

Manufactured by The Abbott Laboratories.

Novocain Base, N. N. R.—*Procaine Base*—Para-amino-benzoxydiethylamino-ethane—$C_6H_4.NH_2COO.C_2H_4.N(C_2H_5)_2$—The base contained in procaine.

A white, odorless, granular powder; permanent in air; insoluble in water; soluble in alcohol, ether, chloroform, and benzene; also soluble in fixed and volatile oils.

Uses and dose—The same as those for procaine hydrochloride. Because of its solubility in oil, it is suitable for an oil spray. A 10 per cent solution in expressed almond oil may be used.

Manufactured by H. A. Metz Laboratories, Inc.

Phenacaine, N. N. R.—*Phenacaina*—Holocaine Hydrochloride—Ethenyl-Paradiethoxy-Diphenyl-Amidine Hydrochloride—$CH_3C:-(NC_6H_4OC_2H_5).(NH.C_6H_4OC_2H_5).HCl.H_2O$—The hydrochloride of phenetidyl-acetphenetidin, a basic condensation product of paraphenetidin (para-ethoxy-amino-benzene) and acetparaphenetidin (phenacetin). Phenacine was first introduced as holocaine hydrochloride.

Small, colorless crystals; odorless; faintly bitter and producing transient numbness on the tongue; permanent in the air.

Phenacaine is soluble in about 50 parts of water; freely soluble in alcohol and in chloroform; insoluble in ether. On boiling in glass vessels, the aqueous solution becomes turbid owing to a separation of a small quantity of the free base by the alkali derived from the glass. Phenacaine forms a clear, colorless solution in water, the solution having a neutral or faintly alkaline reaction on litmus.

Uses—Phenacaine is a local anesthetic like cocaine but having the advantage of a quicker effect. Five minims of a 1 per cent solution when instilled into the eye are usually sufficient to cause anesthesia in from one to ten minutes. This is preceded by temporary smarting.

Dose—It is applied in a 1 per cent aqueous solution. Phenacaine is incompatible with alkalies and their carbonates and the usual alkaloidal reagents. Glass vessels should be avoided in preparing the solution, porcelain being used instead. The solutions are permanent, as the drug is itself antiseptic. They are not injured by boiling.

Manufactured by H. A. Metz Laboratories, Inc.

Procaine Nitrate, N. N. R.—*Procainæ Nitras*—$C_6H_4.NH_2COO.C_2H_4.N(C_2H_5)_2.HNO_3$—1-para-aminobenzoyl-2-diethyl-amino ethanol mononitrate; para-aminobenzoxydiethylamino ethane mononitrate; β-diethylaminoethyl-*p*-amino benzoate mononitrate.

In small colorless and odorless crystals, soluble in water and alcohol. The aqueous solution is neutral in reaction.

Uses—The same as those of procaine. It may be prescribed in combination with silver salts, with which it forms no precipitate.

Dose—Used in 3 per cent solutions.

Manufactured by H. A. Metz Laboratories, Inc.

Saligenin, N. N. R.—*Saligeninum*—Salicyl Alcohol—*o*-Hydroxy-benzyl Alcohol—1 : 2-Phenol-methylol—$C_6H_4(OH).CH_2OH$.

In white rhombohedral plates, or as a white crystalline powder, permanent in air; odor faintly aromatic; taste slightly burning, followed by a sense of numbness. Saligenin is soluble in water and chloroform; freely soluble in alcohol and ether; also soluble in the fixed and volatile oils.

Uses—Saligenin is a local anesthetic similar in action to procaine. It is said to be as effective as procaine but much less toxic; also the anesthesia produced lasts longer and for this reason the addition of epinephrine is not necessary. Weak solutions are relatively ineffective when applied to intact mucous membranes, but strong solutions (12 per cent) exert a definite numbing effect.

Dose—The same as that of procaine.

Stovaine, N. N. R.—Benzoyl-dimethylaminoethylpropanol hydrochloride; dimethylaminoethyl propylbenzoate hydrochloride—$CH_3.CH_2.C(C_6H_5COO)(CH_3)CH_2N(CH_3)_2.HCl$—The hydrochloride of 2-benzoxy-2-methyl-1-dimethylamino butane. It is closely related to alypin.

Small, brilliant scales, which melt at 175° C. It is extremely soluble in water and easily in methyl alcohol and acetic ether, but requires 5 parts of absolute alcohol for solution and is only slightly soluble in acetone. It is quite stable and its solutions may be sterilized at 115° C. without suffering decomposition. The aqueous solution is slightly acid to litmus, neutral to methyl orange. It is precipitated by all the alkaloidal reagents and is decomposed even by very dilute alkalies.

Uses—Stovaine acts as a local anesthetic. It has about the same power as cocaine, but dilates the blood vessels, whereas cocaine contracts them. It is only about one half as toxic as cocaine.

It is used as a local anesthetic.

Dose—Internally, $\frac{1}{30}$ grain (0.002 Gm.) in pill form. Locally it may be used in the eye in 4 per cent solution and applied to other mucous membranes, as in laryngology, in from 5 to 10 per cent solution. For hypodermic injections for local anesthesia it can be used in 0.75 to 1 per cent solution.

Manufactured by Poulenc Frères Company, Paris, France, and distributed by Geo. J. Wallau, Inc., New York.

Butesin, N. N. R.—*n*-butyl-para-aminobenzoate—$C_6H_4NH_2.COO(C_4H_9)$—The normal butyl ester of 4-amino-benzoic acid, $C_6H_4NH_2.COOH$.

A white, crystalline powder, odorless and tasteless. It is almost insoluble in water (about 1 in 7,000); soluble in dilute acids, alcohol, chloroform, ether and benzene; also soluble in fatty oils. Butesin is slowly hydrolyzed when boiled with water.

Uses—The actions and uses of butesin are similar to those of ethyl amino-benzoate (benzocaine), but it is claimed to be more effective.

Dose—Butesin is used as a dusting powder, either pure or diluted. It may be used in the form of troches, ointment, suppositories or dissolved in a fatty oil. Its oil solutions may be sterilized by heat.

Manufactured by The Abbott Laboratories.

Butesin Picrate, N. N. R.—Dinormalbutylparaminobenzoate-trinitrophenol.—$(C_6H_4.NH_2.COO.C_4H_9)_2.C_6H_2(NO_2)_3OH$—Compound consisting of one molecule of trinitrophenol (picric acid) and two molecules of the normal butyl ester of 4-amino benzoic acid.

A yellow, amorphous powder; odorless; taste slightly bitter. One part of butesin picrate is soluble in 1,400 parts of water; also soluble in 100 parts of cottonseed oil; soluble in alcohol, chloroform, ether and benzene.

Uses—Butesin picrate combines the anesthetic action of butesin with the antiseptic properties of trinitrophenol (picric acid). An aqueous solution of 1 : 1,400 produces immediate and complete anesthesia of the eye which lasts from ten to twenty minutes. Butesin picrate is used in the treatment of burns, ulcers and other denuded painful lesions of the skin.

Dose—For use a 1 per cent butesin picrate ointment is proposed.

Manufactured by The Abbott Laboratories.

Orthoform, N. N. R.—*Orthoform-New*—Methyl Metaaminoparaoxybenzoate—$C_6H_4.NH_2.OH.CO.O(CH_3)$, 3 : 4 : 1—The metaaminoparaoxybenzoic acid ester of methyl alcohol.

A fine, white, crystalline powder, neutral in reaction, odorless and tasteless. It is almost insoluble in water; freely soluble in alcohol; soluble in ether. It is decomposed by boiling with water or by warming with alkalies or their carbonates, into methyl alcohol and paraoxybenzoic acid or the alkali salt of it.

Uses—Orthoform is a local anesthetic, but penetrates the tissues very slowly on account of its insolubility. It has no action on the unbroken skin. It is practically non-toxic in the usual doses.

Orthoform is used internally to relieve the pain of gastric ulcer. It has been applied locally as an analgesic to wounds of every description. It has been used in dentistry, in nasal catarrh, hay fever, etc.

Dose—Internally, from 8 to 15 grains (0.5 to 1 Gm.) in emulsion; locally, in substance as a dusting-powder or mixed with lactose for insufflation, dissolved in ether and mixed with oil for pencilings, or as an ointment with wool fat, etc.

Distributed by H. A. Metz Laboratories, Inc.

CHAPTER LX

COLORING PRINCIPLES—NATURAL AND ARTIFICIAL

Coloring principles may be variously classified. They may be grouped as natural or artificial or as animal, vegetable, or mineral. Mineral colors are usually termed pigments and are of importance in the paint industry. The term pigment is also applied generically to plant colors by writers on plant chemistry. Many drugs contain coloring principles which are only incidental to their composition, their principal use being for the therapeutic effect. The green leaf drugs, such as belladonna, digitalis, etc., containing chlorophyll; certain cathartic drugs, such as rhubarb, aloes, etc., and many others are in this class. Some vegetable and animal products ordinarily classed among the drugs are used almost exclusively for coloring. Among these are cudbear, cochineal, red saunders, etc. Then there are artificial colors, usually of coal-tar origin. The number of these is very great. A few are of therapeutic value such as methylene blue and scarlet red.

It has been considered appropriate to include in this chapter such vegetable, animal and artificial products as are used primarily for their coloring effect, discussing some basic coloring constituents, and also the tests for identifying certain types of colors.

Chlorophyll is a complex organic principle found in green vegetable tissue. It originates in the cell constituents known as *chloroplasts*. The name was given to chlorophyll by Pelletier and Caventou, who first studied it. It is a mixture of two closely related substances called *chlorophyll a*, ($C_{55}H_{72}O_5N_4Mg$), and *chlorophyll b*, ($C_{55}H_{70}O_6N_4Mg$). It is insoluble in water but is soluble in certain organic solvents, particularly in ethyl alcohol and methanol.

Accompanying chlorophyll are several other coloring principles collectively known as the *carotinoids*. They are *carotin*, *xanthophyll*, and *fucoxanthin*.

Carotin ($C_{40}H_{56}$) is a hydrocarbon. It occurs largely in the carrot and in flower petals of yellow and red shades and also in green leaves. It is insoluble in water and soluble in most organic solvents, chiefly in petroleum benzin and in alcohol.

Xanthophyll ($C_{40}H_{56}O_2$) is probably an oxidation product of carotin, and may be converted into the latter by reducing agents. It is insoluble in water and in petroleum benzin, sparingly soluble in alcohol, but readily soluble in acetone. It occurs in flower petals and in green leaves.

Fucoxanthin ($C_{40}H_{54}O_6$) is a basic compound occurring chiefly in brown algæ. It is insoluble in water but soluble in methanol.

A number of other coloring principles are more or less generally distributed in the vegetable kingdom, particularly in flower petals.

They are called *anthoxanthins* and include *flavone* and *xanthone*. Flavone ($C_{15}H_{10}O_2$) yields a number of derivatives which also occur in plant tissues. Among these are *chrysin*, *quercetin*, *rhamnetin*, *morin*, and *luteolin*. *Xanthone* ($C_{13}H_8O_2$) yields *euxanthone*, *gentisin*, and *datiscetin*.

The anthoxanthins are almost insoluble in water but are dissolved by acids and by alkalies with the formation of yellow solutions.

The *anthocyanins* are plant coloring principles of a blue, red, or violet tint occurring in flowers, fruits, and leaves. Among these are *cyanin*, *idæin*, *myrtillin*, *œnin*, *delphinin*, *pelargonin*, *althæin* and *malvin*. The anthocyanins

are all glucosidal in character. The derivatives of the anthocyanins are numerous and are productive of most of the innumerable hues of flowers. The anthocyanins as well as many of the derivatives are soluble in water, alcohol, and ether and show color changes in acid and alkaline solutions which makes them valuable as indicators in some cases.

Phycoerythrin is a pigment found in red seaweed. It is soluble in water forming a rose-colored solution with a marked orange fluorescence.

There is a certain structural similarity between chlorophyll, which is an organic magnesium compound, and hemoglobin the coloring principle of the blood, which is a combination of an albuminous group with hematin ($C_{32}H_{30}FeN_4O_3$), an organic iron compound.

The coal-tar colors date from 1856 when W. H. Perkin accidentally discovered *mauveine*, usually known as *Perkin's purple*, while engaged in an unsuccessful attempt to synthesize quinine. Other discoveries along this line followed soon after, and a great industry grew up in the field of coal-tar chemistry, which in its broadest sense includes research on synthetic medicinals as well as coal-tar dyes. The earliest colors were prepared from aniline and for many years all coal-tar dyes were called aniline colors, irrespective of their origin. The coal-tar dyes include more than a dozen well defined groups among which are the *nitroso-dyes*, the *nitro-dyes*, the *azo-dyes*, the *azines*, *oxazines*, and *thiazines*, the *indigoids*, the *anthraquinones*, the *acridines*, the *quinolines*, and others. These in turn are classified as *acid dyes* and *basic dyes*, or *direct dyes* and *mordant dyes*.

Most dyes are used in coloring fabrics and for various artistic purposes. Many coal-tar dyes were originally used in foodstuffs and beverages without careful selection or discrimination between those which were harmless and those which were toxic, and without any supervision as to purity or freedom from poisonous constituents derived from their manufacture.

After the passage of the Food and Drugs Act in 1906, the U. S. Department of Agriculture established regulations by which a few colors came to be known as permitted colors. At the present time the list of permitted colors includes the following:

Red colors: *amaranth*, *ponceau*, and *erythrosine*.
Yellow colors: *naphthol yellow S*, and *tartrazine*.
Orange color: *orange I*.
Blue color: *sodium indigodisulphonate*.
Green color: *light green S. F. yellowish*.

These are only permitted to be used after certification by some competent authority that they are true to name and free from poisonous impurities. Hence the term "*certified*" and "*permitted*" *colors*. The word "permitted" is used in a restricted sense. It does not carry with it the right to use colors for purposes of deception, even though they be "permitted" colors; for all food laws have clauses prohibiting the coloring of foods and beverages in a manner so as to conceal inferiority or to give a false appearance of value.

From this small list of permitted colors, by skilful blending and mixing, may be produced all of the colors that are practical and desirable for legal use in foods, beverages, and pharmaceutical preparations.

Inasmuch as some states limit the use of coal-tar colors or prohibit their use entirely, methods of differentiating between coal-tar colors and those of vegetable or animal origin are important.

The water-soluble coal-tar dyes are either acid or basic. The basic dyes are precipitated from solution by tannin and may be dyed upon strips of pure

white wool, from neutral or slightly alkaline solution. The acid dyes are not affected by tannin and are identified by dyeing upon strips of pure white wool, from slightly acid solution. The dyed wool strips in this case may have the color removed by treatment with weak ammonia solution, when, by removal of the original wool strip and acidulation of the solution, the dyeing can be accomplished a second time upon a fresh strip of wool. This is known as the double dyeing test and serves to exclude most vegetable colors. Other tests for the detection of coal-tar colors will be found described under cudbear and carmine.

Official Vegetable or Animal Colors

COCCUS. U. S. Cochineal

Cochineal consists of the dried female insects, *Coccus cacti* Linné (Fam. *Coccidæ*), enclosing the young larvæ.

Description—Somewhat ovate in outline, convex above, concave beneath, from 3.5 to 5 mm. in length, consisting of from 9 to 12 segments; externally grayish-purple or grayish; in the shell-like, somewhat horny abdomen lie numerous larvæ less than 1 mm. in diameter; the mature larvæ with 8-jointed antennæ, 3 pairs of legs, the lower having from 6 to 8 segments, and a characteristic beak or rostrum composed of 4 thread-like parts which pair off into 2 coils; easily pulverizable; odor characteristic; taste slightly bitter.

For further description and tests, see the U. S. P. X.

U. S. P. Preparation—Tinctura Cardamomi Composita.

N. F. Preparation—Liquor Cocci; Syrupus Asari Compositus; Tinctura Kino et Opii Composita.

Cochineal owes its red color to *carminic acid* or *carmine-red*, $C_{11}H_{12}O_6$. $2H_2O$, which is present to the extent of 8 to 10 per cent. This substance may be precipitated by most metallic salts; aluminum hydroxide forms what is termed a *lake*. It is very soluble in ammonia water and advantage is taken of these facts in preparing the N. F. solution of cochineal and carmine. It contains mucilage, fat, inorganic salts, etc.

Uses—Its only use in pharmacy is to impart a bright red color to various preparations, like compound tincture of cardamom, elixirs, etc.

LIQUOR COCCI. N. F. Cochineal Color

[**Liq. Cocci**—Liquor Coccineus]

	Metric	Alternative
Cochineal, in fine powder	**65 Gm.**	2 oz. av. 74 gr.
Potassium Carbonate	**32 Gm.**	1 oz. av. 30 gr.
Alum	**32 Gm.**	1 oz. av. 30 gr.
Potassium Bitartrate	**65 Gm.**	2 oz. av. 74 gr.
Glycerin	**450 cc.**	14 fl. oz. 192 min.
Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Triturate the cochineal intimately with the potassium carbonate, then add 500 cc. [1 pint] of water, followed by the alum and potassium bitartrate, successively. Heat the mixture slowly to boiling, in a capacious vessel, set it aside to cool, then add the glycerin and filter the mixture, passing enough water through the filter to make the finished product measure 1000 cc. [2 pints].

Cochineal color is a very brilliant red solution, having a somewhat aromatic odor.

Add 1 cc. of the Solution to 500 cc. of water: a very bright scarlet solution results which darkens upon the addition of ammonia water.

To a mixture of 10 cc. of the Solution and 40 cc. of water, add 1 cc. of diluted hydrochloric acid; immerse in the mixture a piece of white woolen cloth about 2 inches square. Boil the solution for 15 minutes, then remove the cloth, wash it thoroughly in cold water, and place it in a solution of about 20 cc. of water and 1 cc. of ammonia water and gently heat for 15 minutes. Remove the cloth and place a new piece of cloth of the same size in the solution, dilute it to 50 cc., acidify with 2 cc. of diluted hydrochloric acid, and boil for 10 minutes. The second piece of cloth should not be dyed a distinct red color (*coal-tar dyes*).

CARMINUM. N. F. Carmine

[Carmin.]

The aluminum lake of the coloring principle obtained from cochineal. Preserve it in well-stoppered, amber-colored bottles, protected from light.

Preparation—It is prepared from cochineal (see Coccus, page 842).

Official Description—It occurs in irregular, angular, bright red fragments or as a powder. When burned, Carmine emits an odor resembling that of burned feathers.

Odor and Taste—Without odor or taste.

Solubility—Slightly soluble in water to which it imparts a red color; freely soluble in ammonia water and alkaline liquids, forming a dark purplish-red solution.

Tests for Identity—The yield of ash does not exceed 12 per cent.

Impurities and Tests for Impurities—*Tin, Lead, and Soluble Barium Compounds*—Fuse the ash of 1 Gm. of Carmine with 1 Gm. of sodium cyanide, dissolve the fused mass in hydrochloric acid with the addition of a few drops of nitric acid, then dilute it with distilled water to 30 cc. and filter the solution. Separate portions of 10 cc. each of this solution yield no precipitate with hydrogen sulphide T.S. or with sulphuric acid.

Barium Sulphate—Fuse the ash from 1 Gm. of Carmine with a mixture of 1 Gm. of sodium cyanide and 1 Gm. of potassium carbonate, extract the fused mass with boiling distilled water, filter, wash with hot distilled water and dissolve the residue in diluted hydrochloric acid; this solution does not become turbid on the addition of a few drops of sulphuric acid.

N. F. Preparations—Liquor Carmini; Trochisci Phenolphthaleinum.

Uses—It is used exclusively as a red coloring substance. Often used in dental preparations, ointments, and in making cakes and candies. To obtain the maximum color value from the carmine, it should be dissolved in a small amount of strong ammonia water and the solution triturated with the powder to be colored, or, preferably, the N. F. solution may be used. Because of its cost and also because of its lack of permanence, it is now largely replaced in dentifrices and perfumes by aniline dyes.

LIQUOR CARMINI. N. F. Solution of Carmine

[Liq. Carmin.]

	Metric	Alternative
Carmine	**65 Gm.**	2 oz av. 74 gr.
Ammonia Water	**365 cc.**	11 fl. oz. 326 min.
Glycerin	**365 cc.**	11 fl. oz. 326 min.
Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Triturate the carmine to a fine powder, gradually add the ammonia water, and afterwards the glycerin, with constant trituration. Transfer the mixture to a porcelain dish and heat it on a water bath, constantly stirring, until the liquid is entirely free from ammoniacal odor. Then cool the liquid and add sufficient water to make the finished product measure 1000 cc. [2 pints].

Solution of Carmine is a deep reddish liquid free from ammoniacal odor.

Specific gravity: about 1.116 at 25° C.

Evaporate 10 cc. of the Solution at a temperature not exceeding 100° C., it leaves not more than 4.972 Gm. of a thick viscous residue. Incinerate the residue from 10 cc. of the Solution; it leaves not more than 0.046 Gm. of ash.

Dilute 5 cc. of the solution with 100 cc. of water. Lead Acetate T.S. will precipitate the carmine leaving at most a faintly pink, transparent, supernatant liquid.

To 10 cc. of the solution in a beaker, add 10 cc. of dilute sulphuric acid and 50 cc. of water. Add a small piece of white woolen cloth and boil for a few minutes. Remove the fabric and boil first in a very dilute solution of hydrochloric acid and then in water until free from acid. Then remove the color from the fabric by boiling in a weak ammoniacal solution. Now remove the cloth from the solution, and acidulate the latter with hydrochloric acid. Introduce a fresh piece of fabric in this solution and boil. No stain forms upon the fabric (*absence of coal-tar dyes*).

SANTALUM RUBRUM. U. S. Red Saunders

[Santal. Rub.]

Red Saunders is the heart-wood of *Pterocarpus santalinus* Linné filius (Fam. *Leguminosæ*).

Description—Usually in the form of a coarse powder, of a purplish to brownish-red color and nearly odorless and tasteless.

For further description and tests see the U. S. P. X.

U. S. P. Preparations—Tinctura Lavandulæ Composita; Liquor Potassii Arsenitis (from Compound Tincture of Lavender).

Uses—This wood contains *santalic acid* (*santalin*), a resinous substance, *pterocarpin*, and *santal*. It is used solely as a red coloring.

CARAMEL. N.F. Caramel

[**Caram.**—Saccharum Ustum, Burnt Sugar Coloring]

A concentrated aqueous solution of the product obtained by heating sugar or glucose until the sweet taste is destroyed and a uniform dark-brown mass results, a small amount of alkali or alkali carbonate being added while heating (see page 897).

Description and Physical Properties—Caramel is a thick, dark brown liquid having the characteristic odor of burnt sugar and a pleasant, bitter taste.

Caramel mixes clear with water in all proportions, 1 part dissolved in 1000 parts of distilled water yielding a clear solution having a distinct sepia tint. The color of this solution is not changed and no precipitate is formed after exposure to sunlight for six hours. It is soluble in diluted alcohol but is precipitated when the alcoholic content of the solution is increased to 80 per cent by volume, or more. It is insoluble in ether, chloroform, acetone, benzene, petroleum, benzin, or oil of turpentine.

Specific gravity: not less than 1.35 at 25° C.

Spread a thin layer of Caramel on a glass plate; it appears homogeneous, reddish-brown and transparent.

Tests for Purity—No precipitate is produced in 20 cc. of an aqueous solution of Caramel (1 in 20) on the addition of 0.5 cc. of phosphoric acid.

Caramel swells when incinerated and forms a coke-like charcoal, which burns off only after prolonged heating at a high temperature, and yields not more than 8 per cent of ash.

N. F. Preparations—Elixir Ammonii Valeratis (from Compound Tincture of Cudbear); Elixir Cinchonæ Alkaloidorum (from Compound Tincture of Cudbear); Elixir Pepsini et Bismuthi (from Tincture); Elixir Strychninæ Valeratis (from Compound Tincture of Cudbear); Elixir Vanillini Compositum; Syrupus Bromidorum (from Compound Tincture); Tinctura Caramellis; Tinctura Opii et Gambir Composita; Tinctura Persionis Composita.

Uses—It is used to produce a brown color in elixirs, syrups, etc.

HÆMATOXYLON. N.F. Hematoxylon

[**Hæmatox.**—Logwood]

Hematoxylon is the heart-wood of *Hæmatoxylon campechianum* Linné (Fam. *Leguminosæ*).

It contains about 12 per cent of the crystalline substance *hematoxylin*, $C_{16}H_{14}O_6$, a colorless, sweet principle, which is reddened upon exposure to light, and turned blackish-purple upon contact with alkalies, yielding *hematëin*, $C_{16}H_{12}O_6.H_2O$ (see Reagents, Page 1534); it also contains tannin, extractive, and a little volatile oil.

Hematoxylon contains not more than 2 per cent of foreign organic matter.

Description—Usually in small chips, occasionally in billets, reddish-brown, the freshly cut surface dark yellowish-red. Odor faint, agreeable; taste sweetish, astringent.

For further description see the N. F. V.

N. F. Preparation—Extractum Hæmatoxyli.

Uses—A mild astringent; used in diarrhea. Dose, ten to thirty grains (0.6 to 2 Gm.). Hematoxylon is used as an indicator in volumetric analysis and the wood is used in the dye industry.

PERSIO. N.F. Cudbear

Cudbear is a purplish-red powder prepared from species of *Roccella* De Candolle, *Lecanora Acharius*, or other lichens.

Cudbear yields not more than 12 per cent of total ash.

Preparation—This coloring agent is prepared by boiling the lichens with water containing chalk in suspension and then concentrating the liquid in a vacuum to a specific gravity of about 1.06. The lichen residue is then dried, transferred to a large vat, mixed with twice its weight of the concentrated liquid and one-sixth its weight of ammonia water, and kept at a temperature between 25° and 30° C. for two or three months with occasional stirring. Finally the mass is dried and powdered.

Description and Tests—An aqueous or alcoholic preparation of Cudbear is of a deep red color which is rendered lighter in tint by the addition of acids, and is changed to purplish-red on the addition of alkalies.

Agitate 2 Gm. of Cudbear occasionally with 200 cc. of water during thirty minutes and then filter; the deep red-colored filtrate conforms to the following tests: Add to 5 cc. of the filtrate five drops of glacial acetic acid and boil for one minute; then add five drops of stannous chloride T.S., and boil again for one minute; the liquid is only faintly pink (*brazilwood or logwood* which produce solutions of a deep red color); add 25 Gm. of kaolin to 100 cc. of the filtrate in an Erlenmeyer flask, shake frequently during one hour and then filter; the filtrate is almost entirely decolorized in comparison with some of the original filtrate (*a number of coal-tar colors*).

N. F. Preparations—It is used to color the following: Elixir Ammonii Valeratis (from Compound Tincture); Elixir Aromaticum Rubrum; Elixir Cinchonæ Alkaloidorum (from Compound Tincture); Elixir Quininæ Valeratis et Strychninæ (from Compound Tincture); Elixir Strychninæ Valeratis (from Compound Tincture); Elixir Trium Bromidorum; Liquor Antisepticus Alkalinus; Syrupus Bromidorum (from Compound Tincture); Syrupus Phosphatum Compositus (from Tincture); Syrupus Pini Strobi Compositus; Syrupus Pini Strobi Compositus cum Morphina; Tinctura Persionis; Tinctura Persionis Composita.

Uses—It is used as a red color in elixirs, syrups, etc. (see official preparations). Because of the difficulty of extracting it with liquid solvents, and the consequent lack of uniformity in the coloring power of the tincture, the drug, in most cases, is now added directly to the preparations, and, after maceration, the preparation filtered.

Unofficial Vegetable Colors

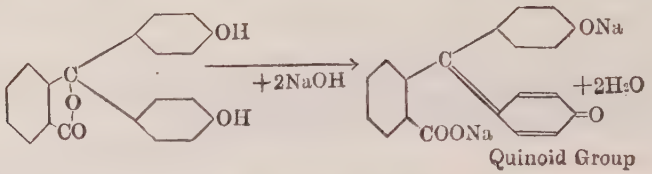
Alkanet	The root of *Anchusa tinctoria*. Used exclusively for coloring oils, ointments, and plasters, which are beautifully reddened by $\frac{1}{10}$ of their weight of the root
Annatto	A coloring substance, consisting of the pulp which surrounds the seeds in the fruit of *Bixa Orellana*. Used for coloring cheese and butter, and for dyeing silk and cotton orange-yellow
Archil	A violet dye obtained from several species of lichens especially *Roccella tinctoria*, *R. fuciformis* and *Lecanora tartarea*. It is fugitive but imparts a brilliant luster. There are three commercial forms: *archil* proper, a pasty mass, *persis*, a mass of drier character, and *cudbear*, a reddish powder (see also page 844)
Brazilwood	The heavy dyewood of *Biancaea sappan* (also known as *sapon wood*). It produces red and purple dyes. Similar wood from other tropical American trees of the species *Caesalpinia* are also sold under this name
Camwood	The hard wood of an African tree (*Baphia nitida*) used as a dye wood. It is one of the more important insoluble redwoods
Carthamus American Saffron. Safflower	Used in infusion. Made in the proportion of two drachms to a pint of boiling water
Catechu	This resin-like substance is used medicinally as an astringent (see page 1096), but is also employed in tanning and used for dyeing brown and composite shades
Fustic	A yellow dye-wood, obtained from *Chlorophora tinctoria* (L.). Gaud. (*Maclura tinctoria* D. Don.), a tree of the Fam. *Moraceæ*, growing in the West Indies and South America. It is not used in medicine or pharmacy
Indigo	This well-known and highly important dye-stuff is obtained from various species of *Indigofera* (Fam. *Leguminosæ*). It is insoluble in water or alcohol but is readily dissolved by concentrated or fuming sulphuric acid, because of the formation of monsulphindigotic and disulphindigotic acids, of which the first is difficultly soluble in water and the second easily soluble. The sodium salt of this latter constitutes the indigo-carmine of commerce. Indigo is soluble in chloroform, aniline, oil of turpentine, paraffin, phenol and benzene It is now almost exclusively produced synthetically. It is an important dye and is rarely used medicinally
Lac Dye	A crimson dye prepared from stick-lac by treating it with a weak alkaline solution and precipitating with alum. Lac is a resinous substance secreted by a scale insect (*Coccus lacca*) which lives on the banyan and other trees. The insects are extensively cultivated
Litmus	See page 1450
Madder	A European herb (*Rubia tinctorium*). The root is used in dyeing. The chief coloring principle being *alizarine*. It was known from antiquity and extensively cultivated until the discovery of a synthetic method of preparing alizarine. Alumina lake of madder is a red pigment, other lakes are prepared as madder orange, madder purple and madder yellow
Quercitron	A yellow dye stuff consisting of the crushed or rasped inner bark of certain oaks (as *Quercus Velutoria*). Quercetin, a yellow, crystalline substance, $C_{15}H_{10}O_7$, is the true dye stuff of quercetron. Quercetin also occurs in apple tree bark, horse chestnut leaves, etc.
Safflower	A dyestuff prepared from the flowerheads of *Carthamus tinctorius* and used in dyeing silk and cotton light red
Saffron	The dried stigmas of *Crocus sativus* containing a deep orange colored substance which has been used in coloring, candy, liquors, and cakes. It is rarely used today
Turmeric	An East Indian plant (*Curcuma longa*). Largely used as a condiment, especially in curry powder. Also used as a yellow dye

Coal Tar Types

The Phenolphthalein Dyes

The following description of the chemistry and therapeutic use of phenolphthalein is taken largely from the 1925 N. N. R.

Phenolphthalein—long used by chemists as an indicator before its therapeutic properties were discovered—is a condensation product of phthalic anhydride and phenol. In neutral and acid mediums it exists in a form in which there is no quinoid group, but the presence of alkali (pH = 8 to 10) causes the characteristic rearrangement with typical salt formation and the presence of a quinoid group whereby the beautiful red color is formed.



This reaction is also characteristic of other members of the series. Phenolsulphonphthalein—which chemists also use as an indicator and which is now official as a diagnostic reagent—contains an SO_2 group in place of the CO group in the phthalic anhydride nucleus. In phenoltetrachlorphthalein, the four hydrogen atoms in the benzene ring belonging to the phthalic acid nucleus have been replaced by chlorine; in tetrabromphenolphthalein, the four bromine atoms are in the phenol groups, two in each; this, it will be noted, is a different substitution than in the case of phenoltetrachlorphthalein.

PHENOLSULPHONPHTHALEINUM. U. S. Phenolsulphonphthalein

[**Phenolsulphonphthal.**—Phenol Red]

A product, $(C_6H_4OH)_2CO.C_6H_4SO_2$ (354.27), of the interaction of phenol and sulphobenzoic acid anhydride, differing from phenolphthalein in that a CO group of the latter is replaced by a SO_2 group.

Description and Physical Properties—A crystalline powder, varying in color from bright to dark red. It is stable in the air.

One Gm. of Phenolsulphonphthalein is soluble in about 1300 cc. of water, 350 cc. of alcohol, and in 500 cc. of acetone. It is almost insoluble in chloroform and ether.

Tests for Identity—It is readily soluble in solutions of alkali hydroxides and carbonates as well as in ammonia water, and in solutions of ammonium carbonate, with a color varying from deep red in concentrated solutions to a violet-tinted red in dilute solutions. The red color is changed to orange or yellow by a slight excess of acid. Its solution in alkali hydroxides is decolorized by warming with zinc dust.

Tests for Purity—Dried to constant weight at 110° C., Phenolsulphonphthalein loses not more than 1 per cent.

Ash: not more than 0.2 per cent.

Fill a 100 cc. glass-stoppered flask with thoroughly boiled and cooled distilled water to within a few cc. of the stopper. Add 1 cc. of an alcoholic solution of Phenolsulphonphthalein (1 in 1000) and 0.5 cc. of fiftieth-normal sodium hydroxide, stopper immediately, and mix well: a strong red color is produced (*sensitiveness*).

To about 1 Gm. of Phenolsulphonphthalein, accurately weighed, add a filtered solution of 0.5 Gm. of sodium bicarbonate in 20 cc. of distilled water. Rotate frequently during one hour, dilute to 100 cc., and let stand over night. Filter through counterbalanced filters or a Gooch crucible, wash at first with 25 cc. of a 1 per cent solution of sodium bicarbonate, then with 25 cc. of distilled water, and dry to constant weight at 110° C.: the weight of the insoluble residue does not exceed 0.2 per cent.

Heat a crucible to redness, and introduce, in small portions, an intimate mixture of 0.2 Gm. of Phenolsulphonphthalein, about 0.5 Gm. of potassium nitrate, and about 0.3 Gm. of anhydrous

sodium carbonate. Maintain a red heat until the reaction ceases, boil the cooled residue for five minutes with 10 cc. of diluted sulphuric acid, filter, and wash the undissolved residue with 10 cc. of distilled water. Evaporate the filtrate and washings until sulphuric acid vapors begin to evolve: the residue dissolved in 5 cc. of distilled water meets the requirements of the test for *arsenic*, page 1512.

Uses—Phenolsulphonphthalein is used for determining the functional activity of the kidney. When injected intramuscularly or intravenously, it begins to be excreted in normal cases in from five to ten minutes. In case of a deficient functional activity, the first appearance of its secretion is delayed. In normal cases, after intramuscular injections, almost the total amount is excreted within two hours (from 60 to 80 per cent.). Failure to excrete nearly the full amount within two hours indicates a deficient functional activity, and the degree of this functional deficiency may be estimated by the proportionate amount excreted within two hours. The average normal eliminations after intravenous administration are from 35 to 45 per cent in fifteen minutes, from 50 to 65 per cent in thirty minutes, and from 65 to 80 per cent in the first hour.

Dose—One cc. of a sterile solution, containing 0.006 Gm. of phenolsulphonphthalein as the monosodium salt, is injected into the lumbar muscles. Great care must be taken that all of the solution is injected.

From twenty minutes to half an hour before administering the test, the patient is given from 200 to 400 cc. of water in order to insure free urinary secretion; otherwise delayed time of appearance may be due to lack of secretion.

Under aseptic precautions a catheter is introduced and the bladder is completely emptied, or the patient is allowed to empty it voluntarily. The time is noted, and 1 cc. of a carefully prepared solution of the phenolsulphonphthalein containing 6 mgm. to the cubic centimeter is accurately administered intramuscularly or intravenously by means of an accurately graduated syringe.

The urine is allowed to drain into a test tube in which has been placed a drop of 25 per cent sodium hydroxide solution, and the time of the appearance of the first faint pinkish tinge is noted.

In patients having no urinary obstruction, the catheter is withdrawn at the time of the appearance of the drug in the urine. If injection is made *intramuscularly*, the patient is instructed to void into a receptacle at the end of one hour and ten minutes, and into a second receptacle at the end of the second hour. If injection is made *intravenously*, the patient is instructed to void into a receptacle at the end of fifteen or thirty minutes or one hour.

When the passing of a catheter is disagreeable and no urinary retention is present, its use can be dispensed with and the time of appearance of the drug can be disregarded.

The urine collected is made alkaline with a 25 per cent solution of sodium hydroxide and then diluted to 1 liter. The solution is thoroughly mixed and a small filtered portion taken, to compare with the standard which is used for all of these estimations. Comparison is made in a colorimeter, a special form of which has been devised for this purpose.

Unofficial Phenolphthalein Dyes

Phenoltetrachlorphthalein-H. W. & D., N. N. R.—*Phenoltetrachlorphthaleinum*—A dibasic dye formed by the condensation of phenol and tetrachlorphthalic acid or its anhydride.

A pink powder; odorless; permanent in the air. It is practically insoluble in water; very soluble in acetone; soluble in alcohol, ether and glacial acetic acid; slightly soluble in chloroform, benzene and carbon disulphide. It dissolves in solutions of the alkalies and carbonates to form solutions which are deep purple when concentrated, but which change to violet-red on dilution, and in very dilute solutions assume a bluish tint (*distinction from phenolphthalein*).

Uses—Phenoltetrachlorphthalein has been used for the determination of the functional activity of the liver. It can be used, *in form of the sodium salt*, intravenously; it cannot be given subcutaneously or intramuscularly. It has been proposed that the excretion can be determined by any one of these methods:

1. The excretion of the drug in the stool.
2. The excretion of the drug in the duodenum by means of a duodenal tube.
3. Its disappearance from the blood stream.

Dose—From 0.05 to 0.4 Gm. administered in the form of the disodium salt. The solution must not be exposed unduly long, as the salt is sensitive to the action of the carbon dioxide of the atmosphere.

Manufactured by Hynson, Westcott & Dunning.

Tetrabromphenolphthalein Sodium, N. N. R.—*Tetrabromphenolphthaleini Sodium*—$NaOOC.C_6H_4C : C_6H_2Br_2O.C_6H_2Br_2ONa$—The sodium salt of a dibasic dye, tetrabromphenolphthalein. The sodium salt contains about 47 per cent of bromine.

A purple powder, odorless. It is very soluble in water; its aqueous solution has a reaction of pH = 8 to 10. It is very slightly soluble in alcohol, insoluble in ether.

Actions and Uses—Tetrabromphenolphthalein sodium is used for the roentgenologic examination of the gall bladder. Following intravenous injection, the substance appears in the gall bladder in sufficient concentration to cast shadows to the roentgen ray.

Dose—A dose of 0.1 Gm. per kilogram has been found sufficient to cast a shadow. To visualize the gall bladder in the patient, 4.5 to 5 Gm. of tetrabromphenolphthalein sodium (which has not undergone change by exposure to light) are dissolved in 35 to 40 cc. of freshly distilled water and filtered. The solution is then sterilized by heating the container in boiling water for twenty minutes. This dose is sufficient for a person weighing 125 pounds or more and should be reduced for patients weighing less. The solution is given intravenously with a syringe in two doses, one-half hour apart, in the morning before breakfast. Care should be taken not to allow extravasation on account of tissue necrosis.

Bromsulphalein-H. W. & D., N. N. R.—Disodium phenoltetrabromphthaleinsulphonate—$O.CO.C_6Br_4.C[C_6H_3(OH)SO_3Na]_2$—The disodium salt formed by the interaction of tetrabromphthalic acid (or anhydride) and phenol with subsequent sulphonation. It contains from 37 to 38 per cent of bromine.

A white, crystalline powder, soluble in water, insoluble in alcohol or acetone. The aqueous solution is almost colorless.

Uses—Bromsulphalein-H. W. & D. is used as a test of liver function; the amount remaining in the blood stream after intravenous injection, as determined colorimetrically, is considered a measure of hepatic dysfunction.

Dose—0.002 Gm. per kilogram of body weight is injected intravenously in 5 per cent aqueous solution without dilution. To carry out the test, the solution of salt may be injected into an arm vein; thirty minutes after the injection, a specimen of blood (from 4 to 5 cc.) is drawn, preferably from the opposite arm, by allowing the blood to run from the needle directly into a dry test tube; after the blood has coagulated it is centrifugalized and the serum is pipetted into two small test tubes; to one of these is added one or two drops of a 10 per cent solution of sodium hydroxide, and to the other tube, a drop of hydrochloric acid; the amount of dye present is determined by comparison with a series of standards.

Manufactured by Hynson, Westcott & Dunning.

Tetrabromophthalein Sodium (Formerly called Tetrabromphenolphthalein Sodium, see New and Non-official Remedies, 1925, p. 141.

Tetraiodophthalein Sodium, N. N. R.—*Tetraiodophthaleinis Sodium*—Tetraiodophenolphthalein Sodium—$NaOOC.C_6H_4C : C_6H_2I_2O.C_6H_2I_2ONa$—The sodium salt of a dibasic dye, tetraiodophenolphthalein. Tetraiodophthalein sodium contains not less than 53 per cent of iodine.

A dark blue, somewhat hygroscopic, crystalline powder, odorless. It is soluble in water and in alcohol. The aqueous solution (1 : 300) has a reaction of *p*H 7 to 9.

Uses—Tetraiodophthalein sodium is used for the roentgenologic examination of the gall bladder. Following the intravenous injection or, if decomposition is avoided, the oral administration, the substance appears in the normal gall bladder in sufficient concentration to cast a shadow to the roentgen ray.

Dose—To visualize the gall bladder in a patient weighing between 115 and 160 pounds, 3 Gm. of tetraiodophthalein sodium is dissolved in 24 cc., or 3.5 Gm. of tetraiodophthalein sodium is dissolved in 28 cc. of freshly distilled water; the solution is then sterilized by heating the container in boiling water for twenty minutes. For patients weighing less than 115 pounds, the amount of salt is to be reduced. The solution is injected intravenously in two doses, one-half hour apart in the mornings before breakfast. Care must be taken not to allow extravasation on account of tissue necrosis. Breakfast is omitted. At noon a glass of milk is permitted, and the evening meal is allowed as usual. Water by mouth is allowed at all times.

Tetraiodophthalein sodium may be administered orally in the form of capsules or pills coated with phenyl salicylate. The average dose is 5 Gm., administered in five capsules or pills of 1 Gm. each during the evening meal. Breakfast is omitted. Since the capsules may not be dissolved, any evidence of abnormality found by the oral method should be checked up by the intravenous method.

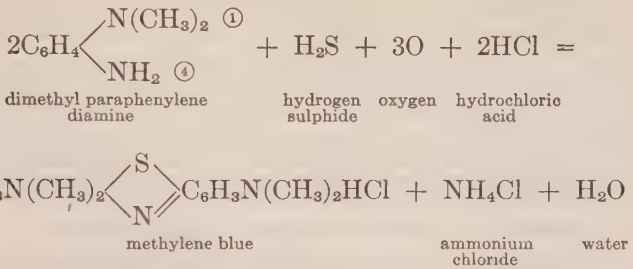
METHYLTHIONINÆ CHLORIDUM. U. S. Methylthionine Chloride

[**Methylthionin. Chlor.**—METHYLTHIONINÆ HYDROCHLORIDUM, U. S. P. IX, METHYLENE BLUE]

Tetramethylthionine chloride [$C_{16}H_{18}N_3ClS.3H_2O$ = 373.82].

Preparation—It is made by treating an acid solution of dimethylparaphenylene diamine with hydrochloric acid, hydrogen sulphide, and ferric chloride as the oxidizing agent.

The reaction is expressed thus:



Description and Physical Properties—Dark green crystals or a crystalline powder, having a bronze-like luster. It is odorless, and is stable in the air.

Methylthionine Chloride is freely soluble in water and in alcohol; soluble in chloroform, the solutions having a deep blue color.

Tests for Identity—The addition of hydrochloric acid to its aqueous solution changes the color to a lighter shade of blue. The addition of sodium hydroxide T.S. changes the color to a purplish shade, and, if added in excess, produces, on standing, a precipitate having a dull violet color.

A solution of Methylthionine Chloride in diluted sulphuric acid is gradually decolorized upon the addition of zinc dust.

Tests for Purity—Methylthionine Chloride, dried to constant weight at 110° C., loses not more than 16 per cent (*moisture*).

Ash: not more than 1 per cent.

Intimately mix 0.2 Gm. of Methylthionine Chloride with about 0.5 Gm. each of powdered potassium nitrate and anhydrous sodium carbonate, and heat the mixture in a crucible until the organic matter is completely oxidized. Dissolve the cooled residue in 15 cc. of diluted sulphuric acid, and evaporate the solution over a flame until the vapors of sulphuric acid begin to evolve: the residue so obtained meets the requirements of the test for *arsenic*, page 1512.

Heat 0.5 Gm. of Methylthionine Chloride at a temperature below a red heat until it is completely carbonized, boil the powdered residue with 10 cc. of diluted hydrochloric acid for five minutes, filter, and wash the residue with 10 cc. of distilled water. Boil the combined filtrate and washings with 1 cc. of nitric acid, supersaturate with ammonia T.S., and filter if necessary: the liquid remains clear upon the addition of an equal volume of hydrogen sulphide T.S. (*zinc*).

Dissolve 1 Gm. of Methylthionine Chloride in 50 cc. of boiling alcohol, filter through counterbalanced filters, wash the residue on the filter with boiling alcohol until the washings cease to be colored blue, and dry it at 100° C.: the weight corresponds to not more than 1 per cent (*dextrin*).

Uses—Methylene blue, as it is usually called, is used as an antiperiodic and analgesic, also in gonorrhea. Its intense and persistent color makes it a difficult substance to dispense easily. It is administered most satisfactorily in capsules, in doses of two to four grains (0.125–0.25 Gm.).

SODII INDIGOTINDISULPHONAS. U. S. Sodium Indigotindisulphonate

[Sod. Indigotin.—Indigo Carmine, Céruléine]

Chiefly the sodium salt [$C_{16}H_8O_2N_2(SO_3Na)_2 = 466.28$] of indigotindisulphonic acid.

Preparation—It may be made by adding sodium carbonate to a solution of indigotindisulphonic acid, the latter being prepared by gradually adding powdered indigo to strong sulphuric acid, keeping the mixture cold during the reaction, and washing and drying the precipitate.

Description and Physical Properties—A blue powder or a dark purple paste.

When compressed, it acquires a coppery luster.

Sodium Indigotindisulphonate is sparingly soluble in water, yielding a dark blue solution. It is almost insoluble in alcohol.

Tests for Identity—If in the form of a paste, Sodium Indigotindisulphonate should be deprived of water by drying to constant weight at 100° C. before applying the following tests:

The addition of nitric acid, bromine T.S. or chlorine T.S. to an aqueous solution of the salt (1 in 200) discharges the blue color. The blue color is also discharged by warming the solution with sodium hydroxide and zinc dust or with stannous chloride T.S.

Tests for Purity—Dissolve 1 Gm. of Sodium Indigotindisulphonate, previously dried to constant weight at 100° C., in 200 cc. of distilled water, filter the solution through counterbalanced filters or a Gooch crucible, wash the residue and the filters with distilled water until the washings cease to be colored blue, and dry at 100° C.: the residue remaining on the filter does not exceed 2 per cent.

Boil 0.2 Gm. of Sodium Indigotindisulphonate for two minutes with 10 cc. of distilled water, cool, and then agitate the solution with small portions of bromine T.S. until the blue color disappears. On now adding a few drops of potassium iodide T.S. to the liquid, no blue color is produced (*starch or starch iodide*).

Add 15 cc. of hydrogen dioxide T.S. and 10 cc. of sodium hydroxide T.S. to 0.2 Gm. of the salt, shake the mixture until the blue color disappears, evaporate the liquid to about 10 cc., cool, acidulate with hydrochloric acid and add a few drops of ferrous sulphate T.S.: no blue color is produced (*iron ferricyanide or ferrocyanide*).

U. S. P. Preparation—Toxitabellæ Hydrargyri Chloridi Corrosivi.

Uses—In the U. S. P. it is recommended as a blue coloring for "Bichloride Tablets", being preferable to other blue dyes because of its stability. It is also used as a dye and for the volumetric estimation of oxidizing agents such as nitrates and chlorine.

Unofficial Coal-Tar Dyes

The N. N. R. (1925) describes and classifies "medicinal dyes", and the following general information is from that source:

The dyes which have been introduced in medicine, for the most part in the last decade, are practically all organic synthetics. Roughly they may be divided into five classes: (1) the *azo dyes*, of which scarlet red medicinal, scarlet red sulphonate and dimazon have been in use for considerable time; (2) the *acridine dyes*, such as acriflavine, neutral acriflavine and proflavine; (3) the *fluoresceine dyes*, either as fluorescein or combined with the metal mercury, such as mercurochrome-220 soluble and flumerin; (4) the *phenolphthalein dyes*, such as phenolphthalein and phenolsulphonphthalein, which are official in the U. S. P., and the unofficial chlorine and bromine substitution products; (5) the *triphenylmethane* or *rosaniline series*, which comprise a large list of substances used in the industries, extensively in laboratory practice and more recently in medicine, such as gentian violet, crystal violet, methyl violet and fuchsin; (6) *miscellaneous dyes*, including such dyes as methylene blue and sodium indigotindisulphonate of the U. S. P. Much confusion has existed concerning the composition of dyes, various manufacturers of commercial dyestuffs making similar dyes of varying composition both qualitatively and quantitatively; usually the commercial dye contains a diluent, such as dextrin or salts, and is judged by tinctorial power. In order to obtain comparable results when employed clinically, the dyes should be of constant composition, preferably without diluent.

The Azo Dyes

The azo dyes have been used in medicine for many years—more generally recalled under the name "scarlet R". The exact constitution of the "scarlet R" dyes which have been used seems to have varied in minor details with different investigators. Chemically they have been azo compounds (that is, they contain the linkage —N : N—) combined with betanaphthol. In the N. N. R., a distinction between two scarlet R compounds has been made; scarlet R medicinal Biebrich is described as toluylazotoluylazo-betanaphthol; scarlet red sulphonate is described as the sodium salt of azobenzenedisulphonic acid azobetanaphthol; it differs from the former in that the methyl group (CH_3—) of toluyl radicles has been replaced by sodium sulphonate (—SO_3Na) groups.

In addition to the scarlet R compounds is the chemically related diacetylamido-azotoluene (dimazon); this contains only one azo group and has a diacetylamido [$(CH_3CO)_2N$—] group.

Scarlet Red Medicinal Biebrich, N. N. R.—*Rubrum Scarlatinum*—Toluylazotoluylazo-β-naphthol —$CH_3C_6H_4N : NC_6H_3.CH_3N : N.C_{10}H_5.OH$—A compound of betanaphthol and diazotized amido-azo-ortho-toluol.

A dark, brownish-red powder, nearly insoluble in water, slightly soluble in benzene and acetone and easily soluble in chloroform, oils, fats and phenols. It is slightly soluble in cold alcohol, somewhat more soluble in hot alcohol, while warm petrolatum and paraffin dissolve rather large quantities.

Uses—Scarlet red medicinal Biebrich and scarlet red sulphonate have a marked power of stimulating the proliferation of epithelial cells. They are used to promote the growth of epithelium in the treatment of burns, wounds, chronic ulcers, etc. In chronic ulcers, however, it is requisite that the local circulation be good in order to obtain a permanent result.

Dose—The scarlet red preparations are generally used in the form of an ointment containing from 4 to 8 per cent of the substance. The 8 per cent ointment is somewhat irritating and should be alternated with a soothing ointment.

Scarlet Red Sulphonate, N. N. R.—The sodium salt of azo benzene disulphonic acid azobetanaphthol —$C_6H_4.(SO_3Na)N : N.C_6H_3.(SO_3Na).N : N.C_{10}H_6OH$.

A dark, brownish-red powder; odorless. It is soluble in water; slightly soluble in ether, alcohol and acetone; almost insoluble in chloroform, benzene, fixed oils, fats and petrolatum.

Uses and dose—The same as for scarlet red medicinal.

Dimazon, N. N. R.—Diacetylamidoazotoluene—$CH_3.C_6H_4.N : N.C_6H_3(CH_3)N(CH_3CO)_2$.

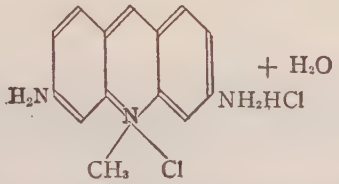
Dimazon is prepared by the acetylization of amido-azotoluene. It is an orange colored, crystalline powder, insoluble in water but readily soluble in alcohol, ether, chloroform, acetone and benzene, oils, fats and petrolatum. It can be removed from cloth by washing with soap and water. It melts at 75° C.

Uses—Dimazon is generally used in the form of a 2 per cent ointment; it is also employed as a dusting powder (mixed with talcum) or as a solution (in oil).

The Acridine Dyes

The acridine derivatives are mostly yellow dyes—acridine dyes obtained from coal tar—to which the term "flavine" has been applied ("flavine" should more correctly be applied to a vegetable coloring matter). The representative acridine dyes used in medicine are acriflavine, neutral acriflavine, and proflavine. In 1912, Ehrlich found that the acridine dye, diamino-methylacridinium chloride hydrochloride, possessed therapeutic properties when used in trypanosome infections and hence he termed it *trypaflavine*. Later this substance was investigated in England, particularly in regard to its effects as a wound antiseptic, and the name "acriflavine" was applied to it. Another closely related substance, diamino-acridine monohydrogen sulphate, was studied also, to which was given the name "proflavine". A considerable number of bacteriologic and clinical reports on these substances have been published. It appears to be established that these dyes possess marked antiseptic and germicidal properties, and on this account, they have been employed in a number of pathologic conditions.

Acriflavine, N. N. R.—*Acriflavina*—3 : 6-diamino-10-methylacridinium chloride monohydrochloride; 2 : 8-diamino-10-methylacridinium chloride monohydrochloride.



A brownish-red, odorless, crystalline powder. It is soluble in about 3 parts of water and in alcohol, forming dark red solutions which fluoresce on dilution and which have a bitter taste. Nearly insoluble in ether, chloroform, liquid petrolatum, fixed oils and volatile oils.

Uses—The antiseptic action of acriflavine and proflavine does not appear to be weakened in the presence of serum. In the treatment of wounds, it is claimed that acriflavine and proflavine are comparatively free from toxic or irritant action on living tissues and that they do not inhibit appreciably the phagocytic action of the leukocytes on the healing process. Acriflavine is claimed to exert a specific bactericidal action on the gonococcus. The evidence indicates that acriflavine has a greater antiseptic action than proflavine, though the action of acriflavine is slower. Applications of acriflavine, neutral acriflavine and proflavine have been employed in the treatment of wounds, urethritis, gingivitis, gonorrheal conjunctivitis, blenorrhea, eczema, furunculosis, otitis media, and other conditions requiring the use of a germicide. When taken by mouth, the dyes tend to render the urine antiseptic provided the reaction of the secretion be alkaline. The use of neutral acriflavine rather than acriflavine has been suggested in areas where freedom from irritation (due to the acid reaction of acriflavine and proflavine) is desirable. The intravenous use of neutral acriflavine has been proposed, but critical evidence for its necessity is lacking.

Dose—In the treatment of wounds, the solution generally employed is 1 : 1000 in physiological solution of sodium chloride, although weaker solutions may be used. In suppurating wounds, this solution is used for syringing and swabbing the wound after free incision, for irrigation after providing adequate drainage, and for saturating the gauze with which the wound is finally covered. Evaporation should be prevented by protective dressing. In cavities, gauze saturated with the solution may be used as a light packing. Fresh wounds are cleansed thoroughly with the solution, and as much of the solution as possible is left in contact with the injured surfaces. Such wounds may be closed by suture and may be expected to heal by first intention.

In the treatment of open wounds, an ointment has been used which contains 1 per cent of proflavine oleate (prepared from proflavine base) in an ointment base composed of equal parts of petrolatum and calcium carbonate. A thick layer of the ointment may be spread on gauze and applied to the surface of the cleansed wound, or the ointment may be spread on the wound directly. The primary dressing need not be changed for several days.

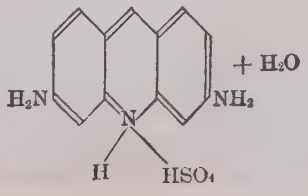
In gonorrhea, a strength of 1 : 1000 in physiological solution of sodium chloride may be used for injection into the urethra. For irrigation, when relatively large quantities are to be used, a 1 : 4000 solution is preferable because it is less irritating; solutions of from 1 : 6000 to 1 : 10,000 have been used. In throat infections a spray of 1 : 1000 solution is used. In middle ear suppurations a 1 : 500 solution in 50 per cent alcohol is dropped into the ear or the cavity may be packed with gauze wet with the solution. In gingivitis the mouth is irrigated with a 1 : 1000 solution. Solutions of acriflavine, neutral acriflavine and proflavine may be boiled, or heated in an autoclave to 130° C., without decomposition, but they are sensitive to light and should be stored in amber bottles. Solutions over a week old should be discarded.

Neutral Acriflavine, N. N. R.—*Acriflavina Neutra*—The base, 3 : 6—diamino-10-methylacridinium chloride, $C_{14}H_{14}N_3Cl + H_2O$.

A brownish-red, odorless, granular powder. It is soluble in about 3 parts of water, forming a brownish-red solution which fluoresces on dilution and which has a bitter taste; incompletely soluble in alcohol; nearly insoluble in ether, chloroform and the fixed and volatile oils. An aqueous solution of neutral acriflavine (1 : 250) is neutral to congo paper.

Uses—(See Acriflavine, preceding article).

Proflavine N. N. R.—*Proflavina*—3 : 6-diaminoacridinium monohydrogen sulphate; 2 : 8-diaminoacridinium monohydrogen sulphate.

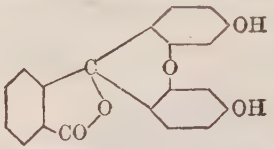


A reddish-brown, colorless, crystalline powder. It is soluble in water and in alcohol, forming brownish solutions which fluoresce on dilution, is nearly insoluble in ether, chloroform, liquid petrolatum, fixed oils and volatile oils.

Uses—(See Acriflavine, preceding article).

The Fluorescein Pyronine Dyes

Fluorescein is formed by combining resorcinol ($C_6H_4(OH)_2$) with phthalic anhydride ($C_6H_4<\begin{matrix}CO\\CO\end{matrix}>O$): at the same time water is given off yielding a product having the structural formula. The product is closely



related to phenolphthalein and its derivatives (which are described in the next section), differing chiefly in the presence of the oxygen molecule between the two ortho positions of the resorcinol nuclei. In common with the phthaleins, it forms salts with alkali whereby a rearrangement takes place and the quinoid group is formed. Flourescein is easily brominated, the tetrabrom compound being the beautiful dye eosin. Fluorescein has been combined with one molecule of mercury (—HgOH), the sodium salt of which is flumerin; in mercurochrome-220 soluble, two of the hydrogen atoms of flumerin have been replaced by two bromine atoms.

Fluorescein, N. N. R.—*Fluoresceinum—Resorcinolphthalein* (a term not strictly correct but commonly used)—Dioxyfluoran—$O : (C_6H_3OH)_2 : C.C_6H_4.COO$—The anhydride of fluoresceinic acid, $O : (C_6H_3OH)_2 : C(OH).C_6H_4(COOH)$.

Uses—The soluble sodium salt of fluorescein (fluorescein 2 Gm., sodium bicarbonate 3 Gm., water to make 100 cc.) has been used for the diagnosis of corneal lesions and the detection of minute foreign bodies embedded in the cornea.

Copper Fluorescein—This is a reddish powder used in trachoma by blowing a minute quantity into the eye. It is prepared by adding a solution of copper sulphate to a solution of fluorescein, collecting, washing and drying the precipitate. *Zinc fluorescein* has also been prepared and used for the same purpose.

The Triphenylmethane (Rosaniline) Dyes

Of the derivatives of triphenylmethane and its homologue tolyldiphenylmethane, the most interesting medicinally are those which result from the introduction of amino groups forming pararosaniline (triaminotriphenylcarbinol ($NH_2C_6H_4)_3COH$) and rosaniline (triaminodiphenyltolylcarbinol ($NH_2C_6H_4)_2(CH_3NH_2.C_6H_3).COH$). On treating rosaniline with hydrochloric acid, the hydroxyl of the carbinol group is split off, permitting the formation of a quinoid group; thus is formed a typical dye known as fuchsin, $NH_2C_6H_4.CH_3.NH_2.C_6H_3.C : C_6H_4 : NH_2.Cl$. The red color of pararosaniline chloride or fuchsin is changed to violet by the entrance of a methyl group in the amino groups, the intensity of the violet color increasing with an increasing number of methyl groups. Thus, there is the closely related gentian violet, crystal violet and methyl violet. Gentian violet is a mixture of pentamethylpararosaniline chloride and hexamethylpararosaniline chloride; by some it is defined as a mixture of methyl violet and crystal violet. Crystal violet is a relatively pure form of hexamethylpararosaniline chloride; methyl violet is considered to contain mostly pentamethylpararosaniline chloride with some of the hexa derivative and probably some tetra derivative also. Hence, one definition of gentian violet is practically the same as the other. It seems likely that in therapeutics it will be found that there is little difference between the penta and hexa derivatives and the mixtures of the two, so that the one most easily obtained in pure form (crystal violet) will be the one most used. The material which has been used by the workers so far, however, has been gentian violet.

Gentian Violet Medicinal, N. N. R.—A mixture of pentamethylpararosaniline and hexamethylpararosaniline chlorides.

A dark green ("bronze") powder or greenish glistening pieces having a metallic luster. It is soluble in alcohol or chloroform; insoluble in ether. Its solution in alcohol or chloroform has a deeper hue than the same strength aqueous solution. Concentrated sulphuric acid dissolves methyl violet with an orange to brownish-red color; on slowly diluting this solution in distilled water, the solution assumes a brown, then green and finally a blue color.

Uses—The use of gentian violet in therapeutics has recently been proposed by Churchman, who found that solutions of the dye had a selective action on certain bacteria and that the majority of gram-negative organisms survived exposure to gentian violet solutions in strengths far in excess of that required to kill gram-positive organisms; in fact, the action of the dye is sufficiently selective, so that often a "strain within a species" is not affected. Churchman's work, however, was done largely with a product containing dextrin as a diluent. Gentian violet is stated to possess properties of great penetration; to be bactericidal, also bacteriostatic in vivo toward the selective organisms. Its chief application has been in the treatment of affections of the pleural cavity and of the joints, particularly in empyema and arthritis—affections in which staphylococci, *B. pyocyaneus* and *B. diphtheriæ* are the causative agents. Intravenous injection of the dye in doses of 0.005 Gm. per kilogram of body weight causes marked cyanosis, which persists for a few hours after injection, owing to the intense color of the dye. In feeble patients, cardiac stimulants should be given. Churchman also has found that acid fuchsin (the acid sodium salt of fuchsin disulphonic and trisulphonic acids) is in some respects the opposite of that of gentian violet in selective power, a stained culture of *B. prodigiosus* being killed by the acid fuchsin, while the gram-positive *B. anthracis* would be unaffected. The selective action of acid fuchsin, however, is clearly brought out only when the organisms are exposed to the dye with slight elevation of temperature (about 50° C.). Acid fuchsin is incompatible with gentian violet, and the compatibility of all mixtures of dyes should be determined before any combination is prepared Churchman claims, however, that acriflavine possesses much the same selectivity as acid fuchsin, so he has proposed the use of a mixture of these two dyes. The effectiveness of such a solution has not yet been established clinically. None of the rosaniline dyes are strong bactericides.

Dose—For direct application, a solution of from 1 : 500 to 1 : 1000 may be employed; for instillation, a 1 : 10,000 solution. For intravenous use, Young and Hill recommend 0.005 Gm. per kilogram of body weight, injected in 0.5 per cent dilution.

Coal-Tar Dyes Largely used as Diagnostic Reagents

Azur II (Azur Blue II, Methylene-Azur II)—A mixture of equal parts of the chlorides of methylene blue (tetramethylthionine) and methylene-azur (methylene blue sulphonate). A dark green powder, entirely soluble in water with a deep blue color, less soluble in alcohol and slightly soluble in chloroform; insoluble in ether. The addition of tannic acid T.S. to an aqueous solution of azur II (1 in 1000) produces a blue precipitate. The addition of a few drops of hydrochloric acid to a mixture of 5 cc. of an aqueous solution of this dye (1 in 1000) and 0.5 Gm. of zinc dust causes decolorization. When the decolorized mixture is filtered, and solution of hydrogen dioxide is added, the deep blue color is restored (reduction to leuco base and re-oxidation). The addition of either hydrochloric acid or ammonia water to an aqueous solution of azur II (1 in 1000) produces no change. The addition of sodium hydroxide T.S. to an aqueous solution of azur II (1 in 1000) produces a violet coloration; upon heating the solution a violet precipitate is formed. The addition of potassium iodide T.S. to an aqueous solution of the dye (1 in 1000) produces a violet precipitate; the addition of potassium dichromate T.S. produces a red violet precipitate. Azur II dissolves in concentrated sulphuric acid with a bright green color [distinction from *methylene violet* (dimethylthionolin)]; upon cautiously diluting with distilled water the solution assumes a blue color, remaining clear. Acidulate an aqueous solution of azur II (1 in 1000) with a few drops of hydrochloric acid, then shake it with ether, remove the ethereal layer, and shake it with a diluted solution of sodium hydroxide T.S.; the latter remains uncolored (distinction from *azur II-eosin*).

Azur II-Eosin—A mixture of methylene blue eosin (methylene blue eosinate and methylene-azur-eosin (methylene blue sulphone-eosinate). A dark green powder only very slightly soluble in water, more readily soluble in alcohol or glycerin. A warm saturated aqueous solution of azur II-eosin (about 1 in 2000) possesses a blue color with intense shading into violet. Highly dilute solutions possess a slight, greenish opalescence. Its solutions in alcohol or glycerin possess the same color with a strong yellowish-green fluorescence. A saturated aqueous solution of azur II-eosin is precipitated upon the addition of tannic acid T.S. The addition of zinc dust and ammonia water to an aqueous solution of this dye causes decolorization. When filtered, the colorless filtrate, upon standing in the air, quickly assumes a blue color (reduction to a leuco base and reoxidation to original color). A hot, saturated and filtered, aqueous solution of azur II-eosin assumes a pale blue color upon the addition of hydrochloric acid, and the dye separates in blue floccules. If this acid solution is agitated with ether and the ethereal layer removed and shaken with diluted sodium hydroxide T.S., the latter assumes an eosin color (distinction from *azur II*). The addition of sodium hydroxide T.S. to a saturated aqueous solution of azur II-eosin intensifies its violet color. Azur II-eosin dissolves in concentrated sulphuric acid with a deep green color which, upon dilution with water, changes to a blue, a portion of the dye (eosin) separating in floccules (distinction from *azur II*).

Dimethylaminoazobenzene (Butter Yellow), $C_6H_5N : N.C_6H_4N(CH_3)_2$—It forms yellow plates melting between 115° and 117° C. It is insoluble in water, soluble in alcohol; soluble in hydrochloric acid with a red color from which solution sodium hydroxide T.S. in excess precipitates the orange-yellow base. The solution of this dye in sulphuric acid is yellow and changes to red on dilution with water.

Eosin A (Yellowish Eosin), $O[C_6H(Br_2O)_2Na]C.C_6H_4COONa$—The sodium salt of tetra-brom-fluorescein. Fine red crystals of bluish, glossy luster, or a brownish-red powder; readily soluble in water, less soluble in alcohol and insoluble in ether. A concentrated aqueous solution of eosin A has a deep brownish-red color while a dilute solution (1 in 500) is yellowish-red with a greenish fluorescence. The alcoholic solutions show a yellowish-green fluorescence. The addition of tannic acid T.S. to an aqueous solution of eosin A (1 in 500), produces no change. When about 0.5 Gm. of zinc dust, followed by 5 cc. of ammonia water, is added to 5 cc. of an aqueous solution of eosin A (1 in 500) and the mixture agitated, rapid decolorization takes place. When this mixture is filtered, the addition of solution of hydrogen dioxide to the filtrate restores the pink-color of the solution. The addition of hydrochloric acid to an aqueous solution (1 in 500) causes an orange precipitate which, upon agitating with ether, yields a yellow solution. This solution is decolorized upon agitating it with a dilute solution of an alkali. The addition of sodium hydroxide T.S. intensifies the color of an aqueous solution of eosin A (1 in 500). Eosin A dissolves in concentrated sulphuric acid (see page 1542) with a yellow color and, when this solution is cautiously diluted with distilled water, a yellowish-red precipitate is produced.

Fluorescein (Resorcinolphthalein)—A derivative [$C_{20}H_{12}O_5$ or $O(C_6H_3OH)_2C.C_6H_4COO$] of resorcinol obtained by the condensation of resorcinol and phthalic anhydride. Fluorescein occurs as a yellowish-red to dark red powder; odorless and tasteless. It is very slightly soluble in water or ether, soluble in alcohol. Fluorescein dissolves in solutions of alkali hydroxides or carbonates, forming a liquid which appears red when observed in transmitted light and fluorescent bright green in reflected light. An alkaline solution of fluorescein, even when highly diluted, shows a greenish-yellow fluorescence, which is discharged by the addition of a slight excess of acid. Incinerate 1 Gm. of fluorescein; the ash does not exceed 0.0025 Gm. Heat about 1 Gm. of fluorescein at a temperature below a red heat until it is completely carbonized, then boil the powdered residue with 10 cc. of diluted hydrochloric acid for five minutes, filter and wash the residue with 10 cc. of distilled water. The combined filtrate, when boiled with a few drops of nitric acid, and supersaturated with ammonia and filtered, if necessary, remains clear upon the addition of an equal volume of hydrogen sulphide T.S. (*zinc*). Shake about 1 Gm. of fluorescein with 20 cc. of distilled water and filter; one drop of tenth-normal sodium hydroxide V.S. imparts to 10 cc. of the filtrate a bright green fluorescence. The addition of a drop of ferric chloride T.S. to the remaining portion of the filtrate does not produce a bluish coloration (*resorcinol and various other phenolic compounds*).

Fuchsin (Basic Fuchsin, Magenta, Rubin, Rosaniline)—The hydrochloride or acetate of rosaniline (triamido-diphenyl-tolyl-carbinol) frequently with the same salts of para-rosaniline (triamido-triphenyl-carbinol). In well developed crystals or irregular crystalline fragments of a glossy, greenish-bronze luster. Soluble in water, alcohol, or amyl alcohol. An aqueous solution (1 in 500), upon the addition of tannic acid T.S., yields a red precipitate. The addition of about 0.5 Gm. of zinc dust (see page 1543), and 10 cc. of ammonia water to 10 cc. of an aqueous solution of fuchsin (1 in 500) produces decolorization when the mixture is well shaken. Place a few drops of this decolorized solution on filter paper, and then add near by a few drops of hydrochloric acid; the zone where the two neutralizing fluids meet assumes a red color. Sulphurous acid (see page 1543), when added slowly, with agitation, to an aqueous solution of fuchsin (1 in 500) causes decolorization. The original color is restored upon the subsequent addition of a solution of formaldehyde. Upon slowly adding hydrochloric acid, to an aqueous solution of fuchsin (1 in 500), the red color gradually changes to a brownish-red which subsequently changes to a yellow when the reagent is in excess. The addition of sodium hydroxide T.S. to an aqueous solution of fuchsin (1 in 500) precipitates the red colored free base. Finely pulverized fuchsin dissolves in concentrated sulphuric acid (see page 1542) with a yellow to yellowish-brown color, which solution, upon the cautious addition of distilled water, becomes yellow to colorless.

Fuchsin, Acid (Acid Magenta, Acid Rubin, Fuchsin S)—Chiefly the acid sodium salt of fuchsin di- and tri-sulphonic acids. Acid fuchsin occurs as metallic, greenish, glistening granules, or as a greenish-brown,

crystalline powder; soluble in water, forming a cherry-red solution, very slightly soluble in alcohol; insoluble in ether. The addition of tannic acid T.S. to an aqueous solution of acid fuchsin (1 in 500) produces no precipitation (*acid color*). The addition of about 0.5 Gm. of zinc dust and 5 cc. of ammonia water to 10 cc. of an aqueous solution of acid fuchsin (1 in 500) produces decolorization when the mixture is well shaken. When this mixture is filtered, the addition of hydrochloric acid to the colorless filtrate restores its original red color. This solution, when agitated with ether, imparts no color to the latter (*phthaleins*). The addition of sodium hydroxide T.S. to an aqueous solution of the salt (1 in 500) almost decolorizes the solution. The addition of hydrochloric acid to an aqueous solution (1 in 500) produces no change. It dissolves in concentrated sulphuric acid with a yellow to brownish-red color and this solution, upon the cautious addition of distilled water, changes to its original fuchsin-red color.

Methyl Violet 6B (Paris Violet 6B)—A mixture of penta- and hexa-methyl-para-rosaniline chlorides. A very dark greenish powder which dissolves readily in water or alcohol, yielding a deep violet solution. Its solution in alcohol or chloroform has a deeper blue color than the aqueous solution. Insoluble in ether. An aqueous solution of methyl violet (1 in 500) when added, drop by drop, to tannic acid T.S. forms a deep blue precipitate (*basic color*). The addition of a few drops of hydrochloric acid to a mixture of about 0.5 Gm. of zinc dust and 5 cc. of an aqueous solution of methyl violet (1 in 500) causes rapid decolorization. Place a few drops of this decolorized solution near a few drops of ammonia water on filter paper; the zone of contact assumes a blue color. Add hydrochloric acid slowly, drop by drop, with agitation, to an aqueous solution of the salt (1 in 500); the violet color gradually changes to blue-green, green, and finally to brownish-yellow, the solution remaining clear. Upon gradually diluting this solution with distilled water, the color changes take place in the reverse order. Add 5 cc. of sodium hydroxide T.S. to 5 cc. of an aqueous solution of methyl violet (1 in 500); a blue precipitate gradually forms and upon heating, the mixture becomes colorless and deposits white floccules. Concentrated sulphuric acid dissolves methyl violet with an orange to brownish-red color; upon slowly diluting this solution with distilled water, the solution assumes a brown, then green, and finally a blue color. Incinerate 1 Gm. of methyl violet; not more than 0.01 Gm. of ash remains.

Methylene Green (Mono-nitro-methylene blue, Tetra-methyl-mono-nitro-thioninchloride), $(CH_3)_2.N.C_6H_3 : N(S)C_6H_2(NO_2).N.(CH_3)_2Cl$—A very dark brown to gray-black powder; soluble in water and slightly soluble in alcohol, yielding greenish-blue solutions. An aqueous solution of methylene green (1 in 500) yields a precipitate upon the addition of tannic acid T.S. The addition of 0.5 Gm. of zinc dust and 5 cc. of ammonia water to 10 cc. of an aqueous solution of the salt (1 in 500) and warming the resulting mixture causes decolorization. Add a few drops of solution of hydrogen dioxide to the decolorized liquid, keeping the solution alkaline; a violet color is produced. The addition of hydrochloric acid to an aqueous solution of methylene green (1 in 500) produces no change; sodium hydroxide T.S. produces a violet precipitate which dissolves upon heating (distinction from *methylene blue*). Methylene green dissolves in sulphuric acid with a green color and on cautiously diluting this solution with distilled water it changes to greenish-blue.

Orange G (the sodium salt of azo-benzene-beta-naphthol disulphonic acid), $C_6H_5. : N.C_{10}H_4(OH)(SO_3Na)_2(2.6.8)$—Orange to brick-red powder, or dark red crystals; readily soluble in water, yielding an orange-yellow solution, slightly soluble in alcohol, insoluble in ether or chloroform. The addition of tannic acid T.S. to an aqueous solution of orange G (1 in 500) causes no precipitation (*acid color*). The addition of hydrochloric acid to a mixture of 0.5 Gm. of zinc dust and 10 cc. of an aqueous solution of the color (1 in 500) produces decolorization. When filtered, the colorless filtrate, on standing exposed to the air, does not regain its original color (presence of *azo group*). When heated, orange G does not deflagrate (distinction from *nitro colors*). The addition of barium or calcium chloride T.S. to a concentrated aqueous solution of orange G produces a colored, crystalline precipitate. The addition of hydrochloric acid to an aqueous solution of the dye (1 in 500) produces no change; the addition of sodium hydroxide T.S. to a similar solution produces a yellowish-red to a bordeaux color but no precipitation. Orange G dissolves in concentrated sulphuric acid with an orange to yellowish-red color; no change in color results upon diluting the solution cautiously with distilled water.

Orcin (Orcinol; Dihydroxy-methyl-benzene 1.3.5.), $C_6H_3(CH_3).(OH).(OH). + H_2O$—In the form of monoclinic prisms, white with a reddish tint, which fuse at about 58° to 60° C. Orcin has an intensely sweet and astringent taste; very soluble in hot water, less soluble in cold water, readily soluble in alcohol or ether. The anhydrous substance fuses between 106° and 108° C. Anhydrous crystals are deposited from an ether solution. When exposed to light or air the crystals assume a reddish-brown color. The addition of a few drops of ferric chloride T.S. to an aqueous solution of orcin (1 in 20) produces a deep blue color. Warm 10 cc. of an aqueous solution of orcin (1 in 10) with 10 cc. of sodium hydroxide T.S. and add a few drops of chloroform; the solution assumes a purple-red color then bright red, and, after diluting with distilled water, shows an intense, greenish-yellow fluorescence. Aqueous solutions of orcin (1 in 20) tested separately do not yield precipitates upon the addition of test solutions of mercuric chloride, cupric sulphate, tannic acid or lead acetate; with basic lead acetate T.S., a white precipitate is obtained (characteristic of *resorcinol derivatives*). Dissolve about 1.3 Gm. of orcin, accurately weighed, in sufficient distilled water to measure 1000 cc. Introduce 25 cc. of this solution, 25 cc. of tenth-normal bromine V.S., and 50 cc. of distilled water into a glass-stoppered flask of about 300 cc. capacity, and then add 25 cc. of dilute sulphuric acid T.S. After thoroughly agitating the mixture, set it aside for ten minutes, then cautiously lift the stopper, quickly introduce 2 Gm. of potassium iodide and close the flask at once. Agitate the solution and, after five minutes, determine the liberated iodine by means of tenth-normal sodium thiosulphate V.S.; conduct a blank experiment, omitting the addition of the solution of orcin and note the number of cc. of tenth-normal sodium thiosulphate V.S. consumed. The difference in cc. of tenth-normal sodium thiosulphate V.S. required in the original titration and the blank test, when multiplied by 0.002068, gives the quantity of anhydrous orcin present, which corresponds to not less than 85 per cent.

CHAPTER LXI

ORGANO-METALLIC COMPOUNDS AND ORGANIC-HALOGEN COMPOUNDS

ORGANO-METALLIC compounds are compounds in which a metal enters into definite chemical combination with or in an organic group. This classification does not include metallic salts of organic acids.

The earliest compounds of this kind to be discovered were zinc ethyl, $Zn(C_2H_5)_2$; zinc methyl, $Zn(CH_3)_2$; lead tetraethyl, $Pb(C_2H_5)_4$, etc.

The latter of these under the name tetraethyl lead has come into prominence as a "carbon knock" remover in motor fuels.

Mercury and arsenic are among the metals occurring in the compounds of therapeutic importance belonging to this class.

Official representatives of this group are the silver protein compounds and the arsenobenzoles. Mercurochrome is an unofficial example.

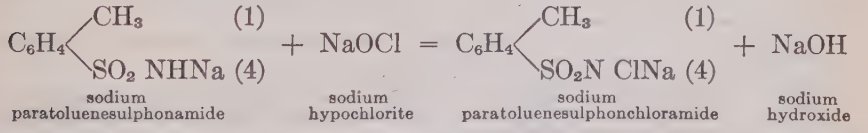
The organic halogen compounds are combinations in which a halogen element enters into intimate combination in an organic group. Chloroform, carbon tetrachloride, the chloramines, chlorinated paraffin, thymol iodide, and thyroxin are official examples of this group.

CHLORAMINA. U.S. Chloramine

[**Chloram.**—SODIUM PARATOLUENESULPHONCHLORAMIDE, CHLORAMINE-T]

Chloramine $[C_6H_4(CH_3)(SO_2NNaCl).3H_2O = 281.67]$ contains not less than 11.5 per cent and not more than 13 per cent of active chlorine.

Chloramine was introduced into medicine during the World War, by H. D. Dakin and his co-workers. It is made from toluene by converting it into p-toluene sulphonic acid. The sodium salt of this acid is then formed and the product, when treated with phosphorous pentachloride, becomes p-toluene sulphonchloride. The next step is to convert this into p-toluene sulphonamide by the action of ammonia. This compound is finally converted into sodium paratoluenesulphonchloramide, or chloramine, by the action of an alkaline solution of sodium hypochlorite, as follows:



Description and Physical Properties—White or faintly yellow crystals, or a crystalline powder, having a slight odor of chlorine. It slowly decomposes on exposure to air, losing chlorine.

One Gm. of Chloramine is soluble in about 7 cc. of water at 25° C. and in about 2 cc. of boiling water. It is decomposed by alcohol, and is insoluble in benzene, chloroform, and ether.

At about 95° to 100° C. Chloramine loses its water of crystallization without decomposition.

Tests for Identity—An aqueous solution of Chloramine (1 in 20) is alkaline to litmus paper or phenolphthalein T. S.

The addition of potassium iodide T.S. to an aqueous solution of Chloramine (1 in 20) causes the liberation of iodine, but bromine is not liberated from alkali bromides unless the mixture is acidulated with an acid (*difference from dichloramine*).

Acids produce in an aqueous solution of Chloramine (1 in 20) a white turbidity or precipitate which redissolves in an excess of alkali hydroxide solutions. When strong mineral acids are used, chlorine is also liberated.

Tests for Purity—On adding 2 cc. of sulphuric acid to 0.1 Gm. of Chloramine, chlorine is evolved but no appreciable darkening occurs (*readily carbonizable substances*).

Assay—Dissolve about 0.5 Gm. of Chloramine, accurately weighed, in 50 cc. of water, add 5 cc. of potassium iodide T.S. and 5 cc. of acetic acid, and allow the mixture to stand in a glass-stoppered bottle for ten minutes. Titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.001773 Gm. of active chlorine.

This assay is explained on page 1465.

Preserve in well-closed containers, protected from light.

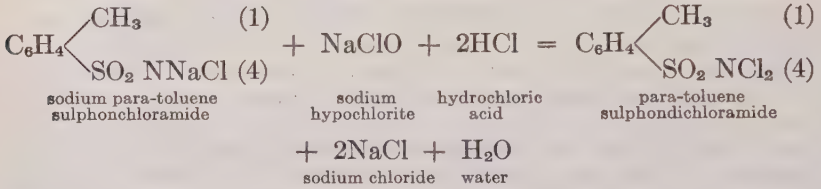
Uses—The actions of chloramine-T are essentially similar to those of surgical solution of chlorinated soda (see page 570). It has the advantages of greater stability, convenience of preparation, and produces less irritation. On the other hand, it lacks the solvent action of alkaline hypochlorites. It is practically non-toxic, but should not be used by mouth, since it is decomposed by the gastric juice. It is used in 0.1 to 4 per cent aqueous solutions. For wounds the normal strength is from 1 to 2 per cent applied by the same technic as the surgical solution of chlorinated soda. It has also been employed for irrigation of the urethra, bladder and uterus, and as a mouth wash.

DICHLORAMINA. U. S. Dichloramine

[Dichloram.—PARATOLUENESULPHONDICHLORAMIDE, DICHLORAMINE-T]

Dichloramine $[C_6H_4(CH_3)(SO_2NCl_2) = 240.08]$ contains not less than 28 per cent and not more than 30 per cent of active chlorine.

Dichloramine was introduced into medicine by H. D. Dakin and his coworkers. It may be prepared by passing chlorine through a solution of paratoluenesulphonamide in caustic soda, the two materials giving the effect of sodium hypochlorite. Upon acidification with acid the dichloramine is precipitated as follows:



Description and Physical Properties—Pale yellow crystals or a yellowish crystalline powder, having an odor of chlorine. It gradually decomposes on exposure to air, losing chlorine.

Dichloramine is almost insoluble in water. It is soluble in eucalyptol and in chlorinated paraffin hydrocarbons, also in glacial acetic acid. One Gm. is soluble in about 1 cc. of benzene or chloroform and in about 2.5 cc. of carbon tetrachloride. It is decomposed by alcohol.

Tests for Identity—Dichloramine melts at about 80° C.

Add about 0.1 Gm. of Dichloramine to 5 cc. of an aqueous solution of sodium bromide (1 in 10): bromine is liberated (*difference from chloramine*).

Strong mineral acids added to Dichloramine liberate chlorine.

Tests for Purity—One Gm. of Dichloramine dissolves completely in 5 cc. of chloroform.

Add 1 cc. of sulphuric acid to 0.1 Gm. of Dichloramine: chlorine is evolved but no appreciable darkening occurs (*readily carbonizable substances*).

Assay—Dissolve about 0.1 Gm. of Dichloramine, accurately weighed, in 20 cc. of glacial acetic acid, in a dry, glass-stoppered bottle. Add 10 cc. of potassium iodide T.S. and 50 cc. of distilled water, allow the mixture to stand for ten minutes, and titrate the liberated iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.001773 Gm. of active chlorine.

This assay is explained on page 1465.

Preserve in well-closed containers, protected from light.

Uses—It is an effective germicide through its content of active chlorine. It is only sparingly soluble in water, but soluble in chlorinated eucalyptol or chlorinated paraffin. The solution produces a gradual sustained antiseptic action.

It is more irritant than chloramine, but also more solvent. It should not be administered internally.

Dichloramine is claimed to be useful in the prevention and treatment of diseases of the nose and throat; it has been used with success when applied to wounds.

Dichloramine, dissolved in chlorinated paraffin, is used in concentrations of from 0.5 to 10 per cent. In nasopharyngeal work from a 1 to 2 per cent solution is employed; for application to wounds a 5 per cent solution. The solution of dichloramine in chlorinated paraffin is not very stable and should not be kept for more than two or three days. At times the solutions may become irritating to the skin because of the formation of hydrochloric acid. Both dichloramine powder and solution should be protected from sunlight to prevent decomposition.

CHLORALIS HYDRAS. U. S. Chloral Hydrate

[Chloral. Hydr.—Chloralum Hydratum U. S. P. IX, "Chloral", Hydrated Chloral]

Chloral Hydrate contains not less than 99.5 per cent of $CCl_3CHO.H_2O = 165.41$.

Preparation—This valuable compound is made by passing dry chlorine gas, in a continuous stream, through absolute alcohol for six or eight weeks. The chlorine is led into cold alcohol at first, and when no more is absorbed the alcohol is heated at first gently and then to 60° C. When saturated, the mixture formed is agitated with sulphuric acid at a temperature of 60° C. for several hours, during which time most of the hydrochloric acid escapes. The separated chloral is then rectified over calcium carbonate. This is anhydrous chloral, a colorless liquid of a penetrating odor, of the specific gravity 1.502. The pure chloral so obtained is then mixed in glass flasks with the necessary amount of water and the resulting hydrated chloral either cast into cakes or purified by crystallization. As solvents for this purpose, certain of the side products of the chloral manufacture, after being purified, and rectified, are used—for instance, ethylene and ethylidene chloride; or, in their absence, chloroform, petroleum benzin, or carbon disulphide may be employed. The name *chloral* is derived from the first syllables of *chlor*ine and *al*cohol.

The reaction may be thus expressed:

$$\underset{\text{alcohol}}{CH_3CH_2OH} + \underset{\text{chlorine}}{2Cl} = \underset{\text{acetaldehyde}}{CH_3CHO} + \underset{\text{hydrochloric acid}}{2HCl}$$

then

$$\underset{\text{acetaldehyde}}{CH_3CHO} + \underset{\text{chlorine}}{6Cl} = \underset{\text{chloral}}{CCl_3CHO} + \underset{\text{hydrochloric acid}}{3HCl}$$

Chloral is thus seen to be acetaldehyde in which three of the atoms of hydrogen have been replaced by three atoms of chlorine; hence it is termed, in systematic nomenclature, *trichloracetaldehyde.*

Description and Physical Properties—Colorless, transparent crystals, having an aromatic, penetrating, and slightly acrid odor, and a slightly bitter, caustic taste. It slowly volatilizes when exposed to the air.

One Gm. of Chloral Hydrate is soluble in 0.25 cc. of water, 1.3 cc. of alcohol, 2 cc. of chloroform, and in 1.5 cc. of ether, at 25° C. It is very soluble in olive oil and freely soluble in oil of turpentine.

Tests for Identity—Chloral Hydrate is decomposed by caustic alkalies, alkali earths, and ammonia, chloroform and a formate of the base being produced. When warmed with a few drops of aniline and sodium hydroxide T.S., the intensely disagreeable odor of phenylisocyanide is developed.

Tests for Purity—Ash: not more than 0.05 per cent.

An alcoholic solution of Chloral Hydrate (1 in 20) does not at once redden moistened blue litmus paper, nor does it at once become opalescent on the addition of a few drops of silver nitrate T.S. (*chloride*).

Shake about 0.5 Gm. of Chloral Hydrate, at intervals of five minutes during one hour, with 5 cc. of sulphuric acid in a glass-stoppered cylinder, which has previously been rinsed with sulphuric acid: the acid remains colorless or very nearly so when viewed transversely in a tube of about 20 mm. diameter (*readily carbonizable substances*).

Gently ignite 2 Gm. of Chloral Hydrate: no inflammable vapors are evolved (*difference from chloral alcoholate*).

Assay—Dissolve about 4 Gm. of Chloral Hydrate, accurately weighed, in 10 cc. of distilled water, add 30 cc. of normal sodium hydroxide, and allow the mixture to stand for two minutes. Add phenolphthalein T.S., and determine the residual alkali at once by titration with normal sulphuric acid. Each cc. of normal sodium hydroxide corresponds to 0.1654 Gm. of $CCl_3CHO.H_2O$.

This assay is explained on page 1460.

Preserve in tightly-stoppered bottles, in a cool place, protected from light.

Uses—Chloral hydrate is used to produce sleep and to check convulsions. It is generally administered in a flavored syrup. Although chloral hydrate is freely soluble in alcohol, the latter is not a suitable solvent, because its therapeutic action is contraindicated: chloral hydrate should not be prescribed with alkalies or alkaline salts on account of its decomposition by them. Dose, 8 to 30 grains (0.5 to 2 Gm.).

CHLORAL CAMPHORATUM. N. F. Camphorated Chloral

[Chloral Camph.]

	Metric	Alternative
Chloral Hydrate	**50 Gm.**	1 oz. av.
Camphor	**50 Gm.**	1 oz. av.
To make	**100 Gm.**	2 oz. av.

Place the camphor and chloral hydrate in a suitable bottle. Stopper the bottle and warm it in a water bath, with frequent agitation, until the mixture is liquefied.

Uses—It is used as a local anodyne.

CHLOROFORMUM. U. S. Chloroform

[Chlorof.]

Chloroform contains not less than 99 per cent and not more than 99.5 per cent of $CHCl_3$ (119.39), the remainder consisting of alcohol.

Caution—Care should be taken not to vaporize Chloroform in the presence of a naked flame, because of the production of noxious gases.

Preparation—Chloroform was formerly made by mixing six parts of chlorinated lime with twenty-five parts of water and, after transferring the mixture to a still, adding one part of alcohol. Heat is applied, and when the temperature of 40° C. is reached, chloroform containing some alcohol begins to distil over. This is washed with water to separate the alcohol, and the heavy liquid is further purified by redistillation.

The reaction probably takes place in several stages according to the following equations:

$$\underset{\text{alcohol}}{C_2H_5OH} + \underset{\text{chlorinated lime}}{CaOCl_2} = \underset{\text{calcium chloride}}{CaCl_2} + \underset{\text{acetaldehyde}}{CH_3CHO} + \underset{\text{water}}{H_2O}$$

$$\underset{\text{acetaldehyde}}{CH_3CHO} + \underset{\text{chlorinated lime}}{6CaOCl_2} = \underset{\text{calcium chloride}}{3CaCl_2} + \underset{\text{calcium hydroxide}}{3Ca(OH)_2} + \underset{\text{trichlor-acetaldehyde}}{2CCl_3CHO}$$

$$\underset{\text{trichlor-acetaldehyde}}{2CCl_3CHO} + \underset{\text{calcium hydroxide}}{Ca(OH)_2} = \underset{\text{calcium formate}}{Ca(CHO_2)_2} + \underset{\text{chloroform}}{2CHCl_3}$$

Chloroform, $CHCl_3$, is termed chemically *trichlormethane*, because it represents a molecule of methane, or marsh gas, CH_4, in which three atoms of

hydrogen are substituted by three atoms of chlorine. It may also be produced by acting on hydrated chloral with an alkali; thus:

$$\underset{\text{hydrated chloral}}{C_2HCl_3O.H_2O} + \underset{\substack{\text{sodium}\\\text{hydroxide}}}{NaOH} = \underset{\text{chloroform}}{CHCl_3} + \underset{\substack{\text{sodium}\\\text{formate}}}{NaCHO_2} + \underset{\text{water}}{H_2O}$$

But chloroform is now more profitably made by reacting on acetone with chlorinated lime; the distilled acetone resulting from the decomposition of crude acetates at high temperatures may also be used. The acetone must be of a high degree of purity; the yield is sometimes nearly 200 per cent. The reaction is as follows:

$$\underset{\text{acetone}}{2CH_3COCH_3} + \underset{\substack{\text{calcium}\\\text{hypochlorite}}}{6Ca(OCl)_2} = \underset{\text{chloroform}}{2CHCl_3} + \underset{\substack{\text{calcium}\\\text{hydroxide}}}{2Ca(OH)_2} + \underset{\text{calcium acetate}}{Ca(C_2H_3O_2)_2} + \underset{\text{calcium chloride}}{3CaCl_2}$$

Absolutely pure chloroform readily decomposes upon keeping, particularly if exposed to the light, and it has long been known that the presence of a very small percentage (0.6 to 1 per cent) of alcohol will act as a preservative.

Description and Physical Properties—A clear, colorless, mobile liquid, having a characteristic, ethereal odor, and a burning, sweet taste. It is not inflammable, but its heated vapor burns with a green flame.

Chloroform is soluble in 210 volumes of water. It is miscible with alcohol, ether, benzene, petroleum benzin, and with fixed or volatile oils.

Tests for Identity—Specific gravity: 1.474 to 1.478 at 25° C.

Chloroform boils at about 61° C., but is volatile even at lower temperatures.

Tests for Purity—Evaporate 50 cc. of Chloroform in a platinum or porcelain dish on a water bath, and dry to constant weight at 100° C.: the weight of the residue does not exceed 0.001 Gm.

Pour 20 cc. of Chloroform, in small portions, upon a piece of clean, odorless, filter paper, laid flat upon a warmed glass plate, and rock the plate from side to side, until the liquid is completely evaporated: no foreign odor becomes perceptible as the last portions disappear from the paper, and the paper remains odorless.

Agitate 10 cc. of Chloroform with 25 cc. of distilled water, and allow the liquids to separate completely. The aqueous layer is neutral to litmus paper and separate portions of 10 cc. each are not affected by a few drops of silver nitrate T.S. (*chloride*), or colored blue by the addition of a few drops each of potassium iodide T.S. and starch T.S. (*free chlorine*).

Transfer 40 cc. of Chloroform to a 50 cc. glass-stoppered cylinder of colorless glass, having an internal diameter of about 20 mm. and previously rinsed with sulphuric acid, add 4 cc. of colorless sulphuric acid, and shake the mixture vigorously for five minutes. Allow the liquids to separate completely, so that both are transparent: the Chloroform remains colorless, and the acid is colorless or nearly so, when viewed transversely in the cylinder (*substances decomposable by sulphuric acid*).

Dilute 2 cc. of the sulphuric acid separated from the Chloroform in the preceding test with 5 cc. of distilled water: the liquid is colorless and clear, and while hot from the mixing emits but a faint, vinous or ethereal odor (*odorous decomposition products*). When further diluted with 10 cc. of distilled water, it remains clear, and is not affected within one minute by the addition of three drops of silver nitrate T.S. (*chlorinated decomposition products*).

Preserve in well-stoppered bottles, in a cool place, protected from light. Protect Chloroform from contact with cork stoppers by covering them with tin foil or other suitable material.

U. S. P. Preparations—Aqua Chloroformi; Linimentum Chloroformi; Pilulæ Phosphori; Spiritus Chloroformi.

N. F. Preparations—Dentilinimentum Aconiti Compositum; Dentilinimentum Aconiti et Iodi Compositum; Elixir Ammonii Valeratis; Elixir Phosphori; Elixir Terpini Hydratis et Creosoti Compositum; Linimentum Aconiti et Chloroformi; Liquor Pancreatini; Mistura Chloroformi et Morphinæ Compositæ; Mistura Opii et Chloroformi Composita; Petroxolinum Chloroformi Camphoratum; Solutio Mastiches Chloroformica Compositum; Solutio Resinæ Chloroformica; Syrupus Pini Albæ Compositus; Syrupus Pini Albæ Compositus cum Morphina.

Chloroform sometimes contains chlorinated decomposition products which render it unfit for its most important use, that of an anesthetic, and the phar-

macist should assure himself that the chloroform he sells for that purpose strictly conforms to all of the tests of the U. S. P.

Chloroform for anesthesia must be preserved in glass bottles. Metal containers are unsatisfactory.

Uses—Chloroform which corresponds to the official tests, or when purified, is used as an anesthetic by inhalation. Taken internally, in small doses, 5 to 15 minims (0.3 to 1 cc.), it is carminative. Externally it is irritant and used in liniments, it may produce blisters. The caution of the U. S. P. to avoid the use of chloroform in the presence of a naked flame is for the purpose of avoiding the development of irrespirable and irritating vapors.

It is used as a preservative in a number of preparations such as the fluid-glycerates, to prevent decomposition during the process of manufacture. In most instances it is evaporated before the product is finished.

CARBONEI TETRACHLORIDUM. U. S. Carbon Tetrachloride

[Carb. Tetrachlor.]

Tetrachlormethane [$CCl_4 = 153.85$].

Carbon tetrachloride is prepared by the action of chlorine upon carbon disulphide under the influence of a catalytic agent.

Description and Physical Properties—A clear, colorless, mobile liquid. It has a characteristic, ethereal odor, resembling that of chloroform.

It is not inflammable. It is slowly decomposed by light if moisture is present.

Carbon Tetrachloride is soluble in 2000 times its volume of water. It is miscible with alcohol, chloroform, ether, benzene, and with petroleum benzin, and dissolves most of the fixed and volatile oils.

Tests for Identity—Specific gravity: from 1.588 to 1.590 at 25° C.

Carbon Tetrachloride boils between 76° and 77° C., but volatilizes at lower temperatures.

Tests for Purity—Evaporate 50 cc. of Carbon Tetrachloride in a dish on a water bath to about 1 cc., and allow to evaporate spontaneously to dryness: the residue, if any, is odorless. Now dry at 100° C., and weigh: the weight of the residue does not exceed 0.001 Gm.

Shake 15 cc. of Carbon Tetrachloride with 25 cc. of distilled water during five minutes, and allow the liquids to separate completely: the aqueous layer is neutral to litmus paper, and 10 cc. portions are not affected by a few drops of silver nitrate T.S. (*chloride*), nor colored blue by the addition of a few drops each of potassium iodide T.S. and starch T.S. (*free chlorine*).

Warm 10 cc. of Carbon Tetrachloride with 10 cc. of a 25 per cent potassium hydroxide solution for five minutes at about 60° C. with frequent agitation: no yellow or brown color develops in either liquid (*aldehyde*).

Transfer 20 cc. of Carbon Tetrachloride to a glass-stoppered cylinder previously rinsed with sulphuric acid. Add 5 cc. of sulphuric acid, shake vigorously for five minutes, and allow the liquids to separate completely: the sulphuric acid layer is colorless or nearly so (*readily carbonizable substances*).

Mix 10 cc. of Carbon Tetrachloride with an equal volume of a 10 per cent potassium hydroxide solution in dehydrated alcohol, and allow the mixture to stand for one hour. Add 5 cc. of acetic acid, and follow with 1 cc. of copper sulphate T.S.: no yellow precipitate is formed within two hours (*carbon disulphide*).

Preserve in well-closed containers, protected from light.

Uses—Carbon Tetrachloride has narcotic and anesthetic properties somewhat similar to those of chloroform. It has recently come into use as a vermifuge in the treatment of hookworm disease. It also removes some intestinal parasites other than the hookworm such as *Oxyuris vermicularis*, *Ascaris lumbricoides* and *Trichocephalus dispar*, but it is less effective against these worms than some other drugs, such as oil of chenopodium. As a vermifuge it appears to be relatively safe, but serious symptoms and even death have been reported, especially in patients addicted to the use of alcohol. During treatment some of the patients complain of headache. Good results are obtained by administration in water or milk or in gelatin capsules on an empty stomach, followed in three hours by a purgative dose of magnesium sulphate. The capsules may be prepared extemporaneously. A mild laxative is generally given to constipated patients on the day previous to treatment. To insure complete removal of the hookworms a test dose of oil of chenopodium, 45 minims (3 cc.),

may be given a week after the treatment with carbon tetrachloride. A second dose of carbon tetrachloride should not be given within three weeks. Alcohol should not be taken during treatment.

Dose—From 30 to 45 minims (2 to 3 cc.). Children, 2 minims (0.13 cc.) for each year of age up to fifteen years. If the drug is to be given with the purgative the dose for adults is administered in 50 cc. (1½ fluidounces) of a solution of magnesium sulphate. For children the dose of the purgative is appropriately reduced. The dose of 3 cc. should not be exceeded.

Unofficial Preparation of Chlorine

Chlorbutanol, N. N. R., *Trichlor-tertiary-butyl Alcohol,* $CCl_3C(OH).CH_3.CH_3$—A white, crystalline, volatile compound having a camphoraceous odor and taste. It is slightly soluble in water ahd very soluble in alcohol.

Uses—A mild local anesthetic, and for insomnia, vomiting, and spasmodic conditions. The dose is from 5 to 20 grains (0.3 to 1.3 Gm.). A saturated aqueous solution may be used hypodermatically. It is also used as a preservative for solutions for hypodermic injection.

For further details see N. N. R., 1925. Manufactured by Parke, Davis and Company.

Unofficial Preparations of Bromine

The following synthetic organic derivatives of bromine are recognized in the N. N. R. and the descriptions given are in the main from that publication. They are intended to produce the sedative action of bromine without the objectionable effects of the alkali bromides. These compounds split off bromine ions in the system, the decomposition being due to the oxidation of the organic substance with which it is combined, but bromine which is too firmly bound may fail to exert its typical effects. The introduction of bromine into compounds already possessing hypnotic or sedative powers may result in increasing the efficiency of these.

Bromeikon, N. N. R.—*Tetrabromphenolphthalein Sodium*—The sodium salt of the dibasic dye, tetrabromphenolphthalein. It contains about 47 per cent of bromine. A purple, odorless powder; very soluble in water, but only slightly soluble in alcohol.

Uses—Tetrabromphenolphthalein Sodium is used for the roentgenologic examination of the gall bladder. For intravenous injection a solution of 4.5 to 5 Gm. in distilled water is filtered and sterilized by heat. It is then administered in two doses a half hour apart, before breakfast. For a more complete description see New and Non-official Remedies, 1925. Manufactured by the Mallinckrodt Chemical Works.

Brometone, N. N. R.—*Tribrom-Tertiary-Butylalcohol—Acetone-Bromoform*—$CBr_3.C(OH)(CH_3).CH_3$.—1,1,1-tribrom-2-methyl-propan-2-ol produced by the reaction of acetone on bromoform. Brometone is claimed to have the sedative action of the bromides without the disadvantage of producing brominism. The dose is 5 grains (0.3 Gm.) five times a day. In adults, it is claimed that it causes no unpleasant results, produces no disturbance of the digestive organs, and has no appreciable effect on the secretions.

Brometone occurs in fine, white, prismatic crystals which possess a camphoraceous odor and taste. It is slightly soluble in water, soluble in alcohol, ether, benzin and most organic solvents. It melts at about 167° C. and volatilizes on exposure to air. Manufactured by Parke, Davis and Company.

Bromipin 10 per cent, N. N. R.—Brominized Sesame Oil. A bromine addition product of sesame oil, containing from 9.8 to 11.2 per cent of bromine in organic combinations.

Bromipin acts like the inorganic bromides; but since it yields its bromine more slowly, it is thought to have less tendency to produce brominism. The combination is not broken up in the stomach; but a portion of the bromine is split off as soon as the compound enters the intestine; the remaining compound is readily absorbed, and, as in the case of other fats, it is largely deposited in the tissues where it is slowly split up. Bromipin 10 per cent is said to be more lasting in its action than the bromides.

Bromipin 10 per cent is a yellow oily liquid having an oleaginous taste.

The dose is 1 fluidrachm (4 cc.) which may be increased in cases of epilepsy to from 2 to 8 fluidrachms, (8 to 30 cc.). It may be given in emulsion with peppermint water and syrup, or pure, flavored with oil of peppermint. Marketed by Merck and Company.

Bromoform, U. S. P. IX, *Bromoformum.*—A liquid consisting of about 96 per cent by weight, of $CHBr_3$ (252.77) and about 4 per cent of dehydrated alcohol. Preserve it in glass-stoppered bottles, in a cool place, protected from light.

Bromoform may be made by the action of bromine on alcohol in the presence of alkalies or alkali hydroxides, but it is preferably made by the reaction of sodium hypobromite upon acetone, just as chloroform is made by the "acetone process"; sodium acetate and sodium hydroxide are by-products.

A heavy, transparent, colorless, mobile liquid. It has an ethereal odor, and a penetrating, sweet taste, resembling that of chloroform. Bromoform is slightly soluble in water; miscible with alcohol, chloroform, ether, benzene, petroleum benzin or fixed or volatile oils. Specific gravity—2.595 to 2.620 at 25° C.

Uses—Care should be taken in dispensing bromoform to see that it is colorless, free from acidity, and that it conforms strictly to the official tests. It is used as a remedy in whooping cough. Owing to its insolubility in water, it may be administered dissolved in alcohol in proper quantity and this solution mixed with glycerin and a flavored syrup. Dose, three minims (0.2 cc.).

Dibromin, N. N. R.—*Dibromobarbituric Acid*—A colorless powder; almost odorless, soluble in about 33 parts of water.

Uses—An antiseptic and germicide for irrigating infected wounds, nonirritating and non-toxic. Use 1 to 10,000 solutions (6 grains per gallon); gradually increase. Manufactured by Parke, Davis and Company.

Sabromin, N. N. R.—*Calbroben—Calcium Dibrombehenate* $Ca(C_{21}H_{41}Br_2.COO)_2$. Sabromin contains not less than 28.5 per cent of bromine.

Sabromin is converted in the stomach into dibrombehenic acid, and this is absorbed from the intestinal tract. The absorption and elimination are slower than that of the inorganic bromides; hence, sabromin is not adapted to conditions in which a rapid saturation of the system with bromine is required. It is indicated in conditions in which the bromides cannot be administered for continued periods without gastric disturbance or in which brominism is caused readily.

Sabromin is a yellowish-white powder; odorless and tasteless. It is insoluble in water and alcohol, but soluble in ether, chloroform, acetone, benzene, petroleum benzin and carbon tetrachloride.

Dose—The dose is 5 to 20 grains (0.3 to 1.2 Gm.)

Distributed by The Winthrop Chemical Company.

CALCII IODOBEHENAS. U. S. Calcium Iodobehenate

[Calc. Iodobehen.—Calioben, Calcium Monoiodobehenate]

Calcium Iodobehenate consists principally of calcium monoiodobehenate $[(C_{21}H_{42}ICOO)_2Ca]$ and contains, when dried to constant weight at 100° C., not less than 23.5 per cent of iodine [I].

Sajodin is one of the brand names for this product. This compound is the calcium salt of an iodine derivative of one of the higher fatty acids.

Description and Physical Properties—A white or yellowish powder, unctuous to the touch. It is odorless or has a slightly fat-like odor.

Calcium Iodobehenate is insoluble in water, very slightly soluble in alcohol and in ether, but freely soluble in warm chloroform.

Tests for Identity—When strongly heated, Calcium Iodobehenate is decomposed, with the evolution of violet vapors of iodine and of white vapors having an odor of burning fat.

Heat about 0.2 Gm. of Calcium Iodobehenate with 2 cc. of sulphuric acid on a water bath during five or ten minutes, cool, add 2 cc. of chloroform, and shake gently: the chloroform, upon separation, is colored violet.

Tests for Purity—Add 10 cc. of diluted hydrochloric acid to 1 Gm. of Calcium Iodobehenate: no effervescence occurs (*carbonate*). Add 40 cc. of distilled water, and boil gently: a layer of fatty acid which is soluble in ether and chloroform separates on the surface. Make the aqueous layer slightly alkaline with ammonia T.S., and add an excess of ammonium oxalate T.S. (about 5 cc.): a white precipitate of calcium oxalate is produced. Allow to stand for four hours, filter, evaporate the filtrate to dryness, and ignite: the residue does not exceed 0.003 Gm. (*magnesium or alkali salts*).

Dried to constant weight at 100° C., Calcium Iodobehenate loses not more than 2 per cent (*water*).

One Gm. of Calcium Iodobehenate dissolves in 10 cc. of warm chloroform with not more than an opalescence.

Triturate 1 Gm. of Calcium Iodobehenate with 10 cc. of distilled water: the mixture is neutral to litmus paper. Add 15 cc. more of distilled water, mix well during five minutes, and filter. Evaporate 10 cc. of the filtrate to dryness on a water bath, and dry to constant weight at 120° C.: the weight of the residue does not exceed 0.001 Gm. (*soluble salts*). Other 5 cc. portions of the filtrate, tested for halogens and sulphate as described under turbidimetric tests, show no greater turbidity than 0.1 cc. of fiftieth-normal hydrochloric acid or sulphuric acid, page 1520.

Add 40 cc. of tenth-normal hydrochloric acid to about 1 Gm. of Calcium Iodobehenate, previously dried to constant weight at 100° C., and accurately weighed, and boiled gently in a flask until thoroughly decomposed. Cool, and titrate the excess of acid with tenth-normal sodium hydroxide, using methyl orange T.S. as indicator: not less than 20 cc. and not more than 20.6 cc. of the tenth-normal acid is consumed.

Assay—Mix about 0.5 Gm. of Calcium Iodobehenate, previously dried to constant weight at 100° C. and accurately weighed, with about 3 Gm. of anhydrous potassium carbonate. Place the mixture in a platinum crucible, cover with about 1 Gm. more of anhydrous potassium carbonate, and heat moderately, gradually increasing the heat, but not exceeding a dull redness, until completely carbonized. Extract the residue with boiling distilled water, and wash it on the filter with boiling distilled water until the washings produce no opalescence with silver nitrate T.S. Heat the combined filtrate and washings, which measure about 150 cc., on a water bath, and add an aqueous solution of potassium permanganate (1 in 20) in small portions, until the hot liquid remains permanently pink. Add just enough alcohol to remove the pink tint, cool to room temperature, dilute to 200 cc., mix well and filter through a dry filter, rejecting the first 50 cc. of filtrate. To 100 cc. of the subsequent clear filtrate add about 1 Gm. of potassium iodide (free from iodate) and an excess of diluted sulphuric acid, and titrate the liberated iodine with tenth-normal sodium thiosulphate, adding starch T.S. near the end of the titration. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.002115 Gm. of iodine.

This assay is explained on page 1465.

Preserve in well-closed containers, protected from light.

Uses—It is used as a substitute for inorganic iodides, the claim being made that it is longer retained and therefore better utilized. The dose is eight grains (0.5 Gm.).

IODOFORMUM. U. S. Iodoform

[Iodof.]

Triiodomethane [$CHI_3 = 393.77$] usually obtained by the action of iodine upon alcohol or acetone, in the presence of an alkali or alkali carbonate.

Preparation—Iodoform may be made by Filhol's process, which consists in heating, in a water bath, one hundred parts of alcohol, two hundred parts

of sodium carbonate, and one thousand parts of distilled water, and gradually adding one hundred parts of iodine in small portions. As the solution becomes colorless iodoform subsides and can be removed by filtration. More iodoform may be obtained from the filtrate by warming, adding another portion of sodium carbonate and of alcohol and passing chlorine into the mixture to liberate iodine which has been combined with the alkali. Chlorine gas is passed through the mixture to cause the separation of the iodoform, which may be filtered out. The filtrate may be concentrated and decomposed by excess of nitric acid. The collected crystals of iodoform are now well washed with the smallest quantity of cold distilled water, spread out on pieces of bibulous paper, and dried in the open air.

The preparation of iodoform may be described by the following equations:

$$\underset{\text{ethyl alcohol}}{CH_3CH_2OH} + \underset{\text{iodine}}{I_2} = \underset{\text{acetaldehyde}}{CH_3CHO} + \underset{\text{hydriodic acid}}{2HI}$$

$$\underset{\text{acetaldehyde}}{CH_3CHO} + \underset{\text{iodine}}{3I_2} = \underset{\text{tri-iodo acetaldehyde}}{CI_3CHO} + \underset{\text{hydriodic acid}}{3HI}$$

$$\underset{\text{tri-iodo acetaldehyde}}{CI_3CHO} + \underset{\text{sodium carbonate}}{Na_2CO_3} + \underset{\text{water}}{H_2O} = \underset{\text{iodoform}}{2CHI_3} + \underset{\text{sodium formate}}{2NaCHO_2} + \underset{\text{carbon dioxide}}{CO_2}$$

The hydriodic acid formed in the first two steps is immediately changed into sodium iodide by the excess of alkali present.

$$\underset{\text{alcohol}}{C_2H_5OH} + \underset{\text{iodine}}{8I} + \underset{\text{acid potassium carbonate}}{2KHCO_3} = \underset{\text{potassium iodide}}{2KI} + \underset{\text{iodoform}}{2CHI_3} + \underset{\text{water}}{3H_2O} + \underset{\text{carbon dioxide}}{2CO_2}$$

It may also be made by adding a solution of chlorinated soda by drops to a solution of 50 Gm. of potassium iodide, 5 Gm. of sodium hydroxide, and 40 Gm. of acetone in 1000 cc. of water, and collecting the crystals of iodoform which separate.

It may be obtained in very fine powder by making a concentrated solution in alcohol, acetone, or one of its other solvents, and pouring this into water, collecting, washing, and drying the precipitate.

The specific gravity of iodoform, about which a controversy existed, was determined by J. Percy Remington to be 4.000; the specific gravity of 2.000 as given in the U. S. P., 1890, was undoubtedly due to the operator taking the specific gravity of the iodoform in water, and when this is done, it is practically impossible to free the crystals from admixed air; the result was reached by using a saturated solution of iodoform in pure kerosene as the liquid, and by calculation obtaining the equivalent in water.

Description and Physical Properties—A fine lemon-yellow powder, or lustrous crystals. It has a peculiar, very penetrating, persistent odor.

Iodoform is practically insoluble in water to which, however, it imparts its odor and taste. One Gm. of Iodoform is soluble in 60 cc. of alcohol, 80 cc. of glycerin, 10 cc. of chloroform, 7.5 cc. of ether, 2.8 cc. of carbon disulphide, and in 34 cc. of olive oil, at 25° C. One Gm. is soluble in about 16 cc. of boiling alcohol.

Iodoform is slightly volatile even at ordinary temperatures, and distils slowly with the vapor of water.

Tests for Identity and Purity—At about 115° C. it melts to a brown liquid, and at a higher temperature decomposes, emitting vapors of iodine.

Its solutions are neutral to litmus paper.

Ash: not more than 0.2 per cent.

On drying 1 Gm. of Iodoform over sulphuric acid for twenty-four hours, it loses not more than 1 per cent.

Shake about 2 Gm. of Iodoform with 5 cc. of distilled water for one minute, and filter: the filtrate is colorless and free from bitter taste (*soluble yellow coloring matter*), and does not affect the color of litmus paper (*acids or alkalies*).

Preserve in well-closed containers, in a cool place, protected from light.

U. S. P. Preparation—Unguentum Iodoformi.

N. F. Preparation—Glycerogelatinum Iodoformi.

Uses—Iodoform is used very largely as an external application to wounds and ulcers. It is also employed in suppositories for hemorrhoids and occasionally internally as an alterative. The dose is one to four grains (0.065 to 0.25 Gm.).

Unofficial Iodoform Preparations

Title	*Directions*
Collodium Iodoformi (N. F. IV)	Dissolve 5 Gm. of iodoform in 95 Gm. of flexible collodion, in a bottle, by agitation
Iodoformum Aromatisatum (N. F. IV)	Mix 96 Gm. of iodoform with 4 Gm. of coumarin
Petroxolinum Iodoformi (N. F. IV)	Dissolve 3 Gm. of iodoform in 20 Gm. of acetone, add 3 Gm. of eucalyptol, 10 Gm. of oleic acid, and 64 Gm. of liquid petroxolin, and mix thoroughly

THYMOLIS IODIDUM. U. S. Thymol Iodide

[Thymol. Iod.]

Thymol Iodide is a mixture of iodine derivatives of thymol, principally dithymol-diiodide $[(C_6H_2.CH_3.C_3H_7.OI)_2 = 550.13]$, containing, when dried to constant weight over sulphuric acid, not less than 43 per cent of iodine.

Preparation—It may be made by adding to 15 parts of thymol and 16 parts of sodium hydroxide in 300 parts of water, a solution of 60 parts of iodine and 80 parts of potassium iodide in water to make 300 parts. The resulting precipitate is washed and dried at 50° C. (122° F.).

Description and Physical Properties—A reddish-brown or reddish-yellow, bulky powder with a very slight, aromatic odor.

Thymol Iodide is insoluble in water and in glycerin; slightly soluble in alcohol; readily soluble in chloroform, ether, collodion, and in fixed or volatile oils, usually leaving a slight residue. It is insoluble in cold or in hot solutions of the fixed alkali hydroxides.

Tests for Identity—When heated with concentrated sulphuric acid, it is decomposed with the separation of iodine.

Tests for Purity—Heat about 0.5 Gm. of Thymol Iodide, accurately weighed, in a porcelain crucible until charred, cool, add five drops of sulphuric acid, and ignite to constant weight: not more than 1.5 per cent of residue remains.

Digest 0.1 Gm. of Thymol Iodide with 50 cc. of warm, distilled water for 10 minutes, filter, cool, add five drops of diluted nitric acid and 1 cc. of silver nitrate T.S.: the turbidity produced, if any, is not greater than that in a control test made with 1 cc. of a solution containing 0.002 Gm. of potassium iodide (*soluble iodides*).

Shake 0.5 Gm. of Thymol Iodide with 10 cc. of distilled water and filter the mixture: the filtrate is not alkaline to litmus paper (*alkalies*), nor is it colored blue upon the addition of a few drops of starch T.S. (*free iodine*).

Assay—Mix thoroughly about 0.25 Gm. of Thymol Iodide, previously dried to constant weight over sulphuric acid and accurately weighed, with about 3 Gm. of anhydrous potassium carbonate. Place the mixture in a platinum crucible, cover with about 1 Gm. of anhydrous potassium carbonate, and heat moderately, gradually increasing the heat, but not exceeding a dull redness, until the mass is completely carbonized. Extract the residue with boiling distilled water and wash it on a filter with boiling distilled water until the washings cease to produce an opalescence with silver nitrate T.S. Heat the combined washings, which measure about 150 cc., on a water bath, and add an aqueous solution of potassium permanganate (1 in 20) in small portions, until the hot liquid remains permanently pink. Add just enough alcohol to remove the pink tint, cool to room temperature, dilute to 200 cc., mix well, and filter through a dry filter, rejecting the first 50 cc. of filtrate. To 100 cc. of the subsequent clear filtrate, add about 1 Gm. of potassium iodide (free from iodate) and an excess of diluted sulphuric acid, and titrate the liberated iodine with tenth-normal sodium thiosulphate, adding starch T.S. near the end of the titration. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.002115 Gm. of iodine.

This assay is explained on page 1465.

Preserve in well-closed containers, protected from light.

Uses—Thymol iodide or *aristol* is used in antiseptic surgery as a substitute for iodoform as an external application to ulcerations and various skin affections. It is sometimes used as a dusting powder in nose and throat diseases.

Unofficial Complex Iodine Compounds

Iodine compounds with proteins and fats have been introduced with claims that they are less irritating to the digestive tract and that they are less inclined to produce the disagreeable symptoms of iodism.

The following preparations are recognized:

Iodalbin, N. N. R.—A compound of iodine and blood albumin, containing approximately 21.5 per cent of iodine.

When administered it passes unchanged into the intestines and is dissolved by the alkaline secretion and on absorption exerts a physiologic action similar to that of the soluble iodides. The dose is 5 to 10 grains (0.3 to 0.6 Gm.). Iodalbin is a reddish-colored powder, practically tasteless and possessing a peculiar, rather pleasant odor, suggestive of cane syrup or molasses. It is almost insoluble in water, acids, alcohol, and other ordinary solvents, but is readily soluble in strong alkaline solutions; more slowly soluble in dilute alkaline solutions.

Manufactured by Parke, Davis and Company.

Iodo-Casein—Casein Iodine, N. N. R.—A compound of iodine with milk casein, containing about 18 per cent of iodine in organic combination.

This drug undergoes practically no change in the stomach, but is said to be digested in the intestines and absorbed. Its advantage is its less rapid absorption and lack of saline taste. Dose, 5 to 20 grains (0.3 to 1.3 Gm.). Iodo-casein is a yellowish-brown powder, almost odorless and tasteless, insoluble in water, or acid solutions. It is partially dissolved and decomposed by alkalies.

Manufactured by the H. K. Mulford Company.

Iodized Fats and Fatty Acids, N. N. R.—Iodized fats and iodized fatty acids produce in general the same systemic effects as ordinary (inorganic) iodides; but their iodine is more slowly absorbed and excreted, and therefore more persistently retained in the tissues, especially in tissues rich in lipoids, such as the nervous structures.

The iodized fats and fatty acids generally pass the stomach unchanged, and are saponified and absorbed in the small intestine, like ordinary fats. They are then deposited for the most part in lipoid tissues, where they are gradually oxidized, yielding inorganic iodide, which is given off to the blood and excreted. The iodine content of the blood is thus maintained more uniformly than when inorganic iodides are administered. The official calcium iodobehenate (page 862) is representative of this class. Other preparations of the same type are as follows:

Iodipin 10 per cent, N. N. R.—*Iodized Sesame Oil 10 per cent*—An iodine addition product of sesame oil containing from 9.8 to 11.2 per cent of iodine in organic combination. It should be exposed to the light to prevent its darkening. Dose, from 1 to 2 drachms (4 to 8 Gm.). Iodipin 10 per cent is a yellow, oily liquid, having a purely oleaginous taste. It is insoluble in water.

Marketed by Merck and Company.

Iodipin 40 per cent is also available.

Iodostarine, N. N. R.—Diiodotariric acid—$C_{18}H_{32}I_2O_2$—An iodine addition product of tariric acid, $C_{18}H_{32}O_2$, derived from the fruit of a species of *Picramnia*. It contains 47.5 per cent of iodine.

The dose is the same as that of potassium iodide. Iodostarine is a white, crystalline solid, odorless and tasteless. It is insoluble in water; slightly soluble in cold alcohol; soluble in warm alcohol, ether, chloroform, benzene, and carbon disulphide. It is permanent in the air.

Manufactured by Hoffmann-LaRoche Chemical Works.

Lipoiodine, N. N. R.—Ethyl diiodobrassidate, $C_{21}H_{39}I_2COO(C_2H_5)$, the ethyl ester of diiodobrassidic acid, $CH_3.(CH_2)_7.CI:CI.(CH_2)_{11}.COOH$, containing 41 per cent of iodine. The dose is from 5 to 15 grains (0.3 to 0.9 Gm.). Lipoiodine crystallizes in white, odorless, and tasteless needles, melting at 37° C. It is insoluble in water, slightly soluble in alcohol and very soluble in fatty oils, ether, and benzene. It is decomposed by exposure to direct light.

Manufactured by the Ciba Company, Inc., New York.

Oridine, N. N. R.—The calcium salt of the iodized fatty acids of cottonseed oil. It contains from 23 to 25 per cent of iodine in organic combination. Oridine is a light brown powder, almost odorless and tasteless. It is almost insoluble in water, benzene, ether, and alcohol; slightly soluble in chloroform and carbon tetrachloride.

It is used for the prophylaxis of goiter in doses of 0.01 to 0.03 Gm. per day until 40 doses have been taken.

Manufactured by Eli Lilly and Company.

Riodine, N. N. R.—A 66 per cent solution in oil of an iodine addition product of castor oil. Riodine contains about 17 per cent of iodine. Riodine is an oil-like liquid, light amber in color, having a faint alkaline reaction. It is insoluble in water; soluble in alcohol, chloroform, and ether. Dose, from 6 to 18 grains (0.4 to 1.2 Gm.).

Distributed by George J. Wallau, Inc.

Ferro-Sajodin, N. N. R.—*Ferioben*—Ferro-sajodin is a basic, ferric iodobehenate, approximate formula $Fe(OH)(C_{21}H_{42}ICOO)_2$, which contains at least 5 per cent of iron and at least 24 per cent of iodine. Ferro-sajodin has the actions of iodides and iron. It is claimed to be more stable and palatable than ferrous iodide, not to injure the teeth or to disturb the gastro-intestinal tract, and that it is free from a constipating tendency. Ferro-sajodin is a reddish-brown, odorless and tasteless powder; unctuous to the touch; insoluble in water or alcohol; slightly soluble in chloroform, ether, and warm fatty oils.

It is indicated in the conditions in which iron and iodides are employed, such as anemia, rickets, syphilis, chronic bronchitis, and arteriosclerosis with anemia in doses from 8 to 15 grains (0.5 to 1 Gm.) daily. For children from 4 to 8 grains (0.25 to 0.5 Gm.) three times daily. Ferro-sajodin is sold in the form of tablets only. These should be masticated before swallowing or crushed when administered to children.

Distributed by The Winthrop Chemical Company, Inc.

Iodeikon, N. N. R.—*Tetraiodophthalein Sodium*—The sodium salt of a dibasic dye, tetraiodophenolphthalein. It contains not less than 53 per cent of iodine. A dark blue, odorless, hygroscopic powder. It is soluble in water and in alcohol.

Tetraiodophthalein sodium is used for the roentgenologic examination of the gall bladder.

It is injected intravenously, 45 grains (3 Gm.) in two doses, a half hour apart, in the morning before breakfast. The solution for injection is made in 24 cc. of distilled water and the solution is sterilized by heat. Tetraiodophthalein sodium is also administered orally in the form of capsules or pills coated with salol. The average dose by this method is 75 grains (5 Gm.), administered in five capsules or pills of 15 grains (1 Gm.) each, during the evening meal.

Manufactured by the Mallinckrodt Chemical Works, St. Louis.

Iothion, N. N. R.—Iopropane; Di-iodo-hydroxy-propane; 1,3-di-iodopropane-2-ol; $CH_2I.CH(OH).CH_2I$—Iothion contains from 77 to 80 per cent of iodine. Used for the systemic effect of iodides by external application. Iothion is absorbed from the intact skin. It is claimed to be practically nonirritating to the skin in the concentrations ordinarily used, and to produce no discoloration.

It is used in the form of *Iothion Oil* (10 per cent), also in solution in alcohol or glycerin, or in the form of ointments containing from 5 to 20 per cent of iothion. It is supplied without friction, and the parts are not bandaged. Iothion is a yellowish, oily liquid having a faint but not unpleasant odor. It is insoluble in water; soluble in alcohol, ether, chloroform, carbon disulphide, glycerin, and oils. It is volatile at body temperature. It is decomposed by alkalies and weakly alkaline solutions.

Distributed by The Winthrop Chemical Company.

Siomine, N. N. R.—Hexamethylenamine tetraiodide $(CH_2)_6N_4I_4$—It contains 78.5 per cent of iodine. It is decomposed in the intestine with formation of hexamethylenamine and iodide, the rate of absorption and excretion being essentially the same as that of inorganic iodides. The administration of siomine provokes the luetin reaction. Hexamethylenamine is present only to render the substance insoluble.

Siomine is a red powder, having a slight, but characteristic odor and taste. When heated to 138° C., it decomposes with violence.

Siomine is slightly soluble in acetone, alcohol, chloroform, carbon disulphide, and ether (with partial decomposition). It is almost insoluble in water, but dissolves with decomposition in aqueous solutions of alkali iodides, of sodium thiosulphate, and in diluted hydrochloric acid. The dose is the same as that of potassium iodide.

Manufactured by Howard-Holt Company.

Another extensively used product not recognized by the N. N. R., is sold under the name *Calcidin*. It is claimed to be a chemical combination of iodine with starch and calcium salts, and contains approximately 15 per cent of available iodine.

It yields iodine readily in the presence of the gastric juice and is employed in catarrhal croup in ⅓ to ½ grain doses, in hot water, repeated every five to ten minutes until relief is obtained or until from 2 to 3 grains are administered. It is also recommended in other conditions in which iodine is indicated. It is manufactured by The Abbott Laboratories.

BITUMEN SULPHONATUM. N. F. Sulphonated Bitumen [Bitum. Sulph.]

Sulphonated Bitumen contains not less than 2.5 per cent of ammonia, not more than 8 per cent of ammonium sulphate, and not less than 10 per cent of total sulphur.

Sulphonated Bitumen belongs to a class of preparations containing as their essential constituents salts or compounds of a mixture of acids containing sulphur and designated by the group name "sulphoichthyolic acid" which are obtained from certain bituminous shales. Sulphoichthyolic acid is characterized by a high sulphur content, the sulphur existing largely in the form of sulphonates, sulphones and sulphides. The ammonium compound of this so-called sulphoichthyolic acid—first introduced as ichthyol—has been used most extensively. Compounds with sodium and other metals, with albumin, with formaldehyde, etc., have also been introduced.

Description and Physical Properties—A viscous fluid obtained by the destructive distillation of certain bituminous schists, sulphonating the distillate and neutralizing the product with ammonia.

Sulphonated Bitumen is reddish-brown to brownish-black in color with a strong, characteristic, empyreumatic odor. It is soluble in water and in glycerin, and is miscible with fixed oils and fats. It is partly soluble in alcohol or ether, and entirely soluble in a mixture of equal volumes of these solvents.

An aqueous solution (1 in 10) may be faintly acid or faintly alkaline to litmus paper. The addition of hydrochloric acid to this solution precipitates a dark resinous mass which is soluble in ether.

Tests for Identity and Purity—Upon boiling an aqueous solution with sodium hydroxide T.S., ammonia is evolved.

Upon incineration, the ash of sulphonated bitumen does not exceed 0.5 per cent.

Upon drying on a water bath to constant weight, sulphonated bitumen loses not more than 50 per cent.

Assay for Ammonia—Accurately weigh about 5 Gm. of Sulphonated Bitumen, dissolve in 100 cc. of water, transfer to a distillation flask, add an excess of sodium hydroxide solution and distil slowly; collect the distillate (about 50 cc.) in 15 cc. of normal sulphuric acid. When the distillation is completed, titrate the excess of sulphuric acid with tenth-normal sodium hydroxide, using methyl orange as indicator. Each cc. of tenth-normal sulphuric acid corresponds to 0.001703 Gm. of NH_3.

This assay is explained on page 1457.

Assay for Ammonium Sulphate—Accurately weigh about 1 Gm. of Sulphonated Bitumen, transfer to a 100-cc. beaker and add 25 cc. of alcohol. Stir thoroughly, filter, and wash the filter with a mixture of equal parts of ether and alcohol until the washings are clear and colorless. Dry the residue on the filter at 105° C., cool, and wash the filter with 200 cc. of warm water slightly acidulated with hydrochloric acid. Determine the sulphate in the solution by precipitation with barium chloride T.S., and after washing, drying, igniting, and weighing, calculate the results to ammonium sulphate.

Assay for Total Sulphur—Dry about 1 Gm. of Sulphonated Bitumen, on a watch glass, to constant weight at 105° C. Pulverize the dried material and transfer about 0.5 Gm., accurately

weighed, to a nickel crucible. Add about 9 Gm. of sulphur-free sodium peroxide, and mix thoroughly. Place the crucible carefully in a beaker containing cold distilled water which should reach about half way to the top. Ignite the dry mixture in the crucible by thrusting a red hot iron wire through a hole in the cover of the crucible. After complete combustion has taken place, tip the crucible and allow the fused mass to dissolve in the distilled water. Add hydrochloric acid in slight excess, heat to boiling and determine the sulphate in the solution by precipitation with barium chloride T.S., and after washing, drying, igniting, and weighing, calculate the results to sulphur. The total sulphur should not be less than 10 per cent.

These assays are explained on page 1480.

Preparations—Collodium Bitumenis Sulphonati; Petroxolinum Bitumenis Sulphonati; Unguentum Bitumenis Sulphonati.

Uses—The current estimate of the effects of sulphoichthyolic acid preparations is based largely on the use of ichthyol. The use of sulphoichthyolate preparations is still largely empiric. They are weakly antiseptic and emollient. Taken internally, they produce some gastro-intestinal irritation, with diarrhea, etc. Dose, three grains (0.2 Gm.).

They were formerly used locally under the supposition that they secure the absorption of swellings and effusions in contusions, burns, etc., and especially in gynecologic practice, and in various skin diseases. They have been tried internally in a great variety of conditions, but there is no evidence that they are of any therapeutic value when used in this way.

A number of more or less related compounds of sulphur have been introduced as substitutes for the sulphoichthyolates under such titles as *ammonium ichthyolate* (manufactured by the Meadows Chemical Company), *hirathiol* (sold by the Takamine Laboratory, Inc.), *ichthynat* (manufactured by the Heyden Chemical Company), *isarol* (manufactured by the Ciba Company), and *ichthyol* (manufactured by Merck and Co.).

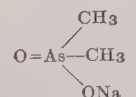
Arsenic and Arsenic Compounds

The N. N. R. (1925) presents the following interesting discussion of the complex arsenic compounds so largely used today in medicine:

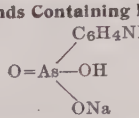
In some of the following compounds the arsenic is pentavalent; in others it is trivalent. A typical arsenic reaction results only from the trivalent arsenic, and in order to secure this action from those compounds containing pentavalent arsenic, their arsenic must be reduced to the trivalent form; this is done by the body, but the rate at which the reduction occurs varies greatly with the different compounds. In some cases, the desirable, as well as the undesirable, effects produced by these compounds are due to the arsenic which is slowly rendered active; in others the therapeutic effects may be due at least in part to the unaltered molecules. The diseases in which arsenic therapy has proved useful are particularly those caused by protozoa. Inorganic arsenic will kill protozoa, but it cannot be administered so as to reach the protozoa in fatal quantity. In the body the organic compounds are less toxic to mammals and more toxic to protozoan parasites. In this way they become available for combating trypanosomes, syphilis, spirillosis, and other protozoan infections.

Among the advantages claimed for, or known to be possessed by, these compounds the following may be mentioned: In those known to produce their effects through the liberation of arsenic, the arsenic is liberated slowly; some remain in the circulating blood for a much longer period than do inorganic arsenic compounds, and thus remain longer in contact with parasites which it is desired to kill; some are specifically etiotropic, that is, they have a much greater affinity for the parasites causing the disease than they have for the tissues of the host.

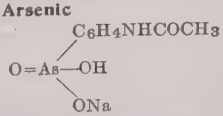
Compounds Containing Pentavalent Arsenic



sodium cacodylate



sodium arsanilate



sodium acetyl arsanilate

Arsanilic acid is derived from arsenic acid, $AsO.(OH)_3$ by replacing one hydroxyl by aniline (phenylamine) $C_6H_5NH_2$; related compounds are made by substituting derivatives of aniline.

The compounds containing pentavalent arsenic are comparatively non-toxic when introduced into the animal system until changes take place that liberate the arsenic. When they are slowly decomposed, they produce favorable effects. If the reduction takes place with greater rapidity, they may produce ordinary arsenic poisoning.

Sodium cacodylate is excreted partly unchanged and partly as cacodylic oxide, which gives a foul odor to the breath, perspiration, etc. Further changes yield products containing inorganic, trivalent arsenic, by which the therapeutic effects are produced.

Sodium arsanilate has been used chiefly against trypanosomes. This salt has no direct action on these parasites, but owes its effects to the products resulting from its reduction in the system. These products appear to be organic compounds containing the arsenic in the trivalent form. Artificial reduction products, which vary according to conditions, are much more active than the arsanilate.

Sodium arsanilate has also been recommended for the conditions which are influenced favorably by other forms of arsenic, but this salt seems to have no advantages over the official preparations of arsenic.

In poisonous doses or when excessive reduction occurs, sodium arsanilate may produce the ordinary toxic effects of arsenic. It acts with especial violence on the optic nerve, producing optic atrophy, frequently resulting in permanent blindness. This may occur unfortunately even with therapeutic doses.

Compounds Containing Trivalent Arsenic

According to Ehrlich's view, only trivalent arsenic is markedly toxic to spirochetes, trypanosomes, etc.; hence he introduced a number of such compounds. Of these only the arsphenamines, in which the toxicity is reduced or modified by the introduction into the molecules of certain groups, are listed below. These compounds have, according to Ehrlich, a special affinity to certain organisms, particularly spirochetes, while their toxicity for the higher animals is comparatively low. The exact fields of usefulness of these compounds and their limitations and also the best methods of administering them, are still under discussion.

The arsphenamines have a direct action on the protozoa and also on some bacteria (anthrax). This activity is enhanced by the presence of enzymes from the liver and especially from the blood.

The toxic actions of arsphenamine are ascribed to the arsenic component in some cases. In other cases the decomposition of the solution has been assigned as a cause. The presence of bacteria in the distilled water is believed to cause the febrile phenomena.

The ratio between etiotropic efficiency and toxicity is far more favorable in arsphenamine than in any of the other organic arsenic compounds thus far tested. Arsenic has been found in the parts infected with syphilis while absent from other localities, indicating that the efficient arsenical compounds combine with the spirochetes or their products in the tissues.

Arsphenamines are contraindicated or should be used with special caution in diseases of the eye of a nonsyphilitic character; in severe affections of the heart and blood vessels, the lungs and kidneys; and in advanced degenerative processes in the central nervous system. They should also be used with caution in infants.

In many cases of apparent toxic action of arsphenamine, the effect is due to improper technic of preparation and administration of the drug rather than to its inherent toxicity.

Arsphenamine and analogous preparations of arsenic used intravenously come under the National law covering serums, viruses, toxins and analogous products, and are subject to the same control.

ARSPHENAMINA. U. S. Arsphenamine

[**Arsphen.**—Diaminodihydroxyarsenobenzene Hydrochloride]

Arsphenamine [$HCl.NH_2.OH.C_6H_3As:AsC_6H_3.OH.NH_2HCl.2H_2O$] contains not less than 30 per cent of arsenic (As), and complies with the requirements of the United States Public Health Service.

Arsphenamine is prepared by reduction, generally with sodium hydrosulphite, of 3-nitro-4-hydroxy-phenyl-arsenic acid. The various modifications of the original method of manufacture deal with different means of obtaining this latter substance.

The manufacture of this product is under the control of the Public Health Service. Each lot manufactured must be approved by the Hygienic Laboratory before being marketed.

Description and Physical Properties—A light yellow powder. It is odorless or has a slight odor, and is hygroscopic. In the dry state or in solution it is oxidized by exposure to the air, becoming darker and more toxic.

Arsphenamine is soluble in water, alcohol, and glycerin, but only very slightly soluble in chloroform and in ether.

Tests for Identity—An aqueous solution of Arsphenamine (1 in 100) is acid to litmus paper (difference from *neoarsphenamine*).

Add sodium hydroxide T.S., drop by drop, to an aqueous solution of Arsphenamine (1 in 100). A precipitate is formed (difference from *neoarsphenamine*), which readily dissolves in an excess of the sodium hydroxide. Sodium carbonate T.S. or solution of sodium bicarbonate also produces a precipitate, but this is insoluble in an excess of the reagent. An aqueous solution of Arsphenamine (1 in 100) is precipitated by mercuric potassium iodide T.S. (difference from *neoarsphenamine*).

An aqueous solution of Arsphenamine (1 in 100) is unaffected by the addition of diluted hydrochloric acid, diluted nitric acid, or by acetic acid even after heating (difference from *neoarsphenamine*). With an excess of hydrochloric acid a precipitate is formed. Diluted sulphuric acid or solutions of alkali sulphates immediately produce a precipitate.

The addition of two drops of freshly prepared ferric chloride T.S. to 5 cc. of an aqueous solution of Arsphenamine (1 in 1000) produces a brownish, violet tinted color, rapidly changing to deep red.

Add 3 cc. of silver nitrate T.S. to 5 cc. of an aqueous solution of Arsphenamine (1 in 100). A red color is produced, but no precipitate is formed even after standing at ordinary room temperature for ten minutes (difference from *neoarsphenamine*). When a 6 cc. portion of silver nitrate T.S. is added to the same volume of solution, a precipitate is immediately formed which blackens on heating. On now adding 5 cc. of nitric acid, and again heating, the precipitate becomes white and dissolves in ammonia water.

The solution resulting from the following assay yields with hydrogen sulphide a yellow precipitate, soluble in ammonium carbonate T.S.

Assay—Place about 0.2 Gm. of Arsphenamine, accurately weighed, in a glass-stoppered, 200 to 300 cc., flask. Add 1 Gm. of finely powdered potassium permanganate and 5 cc. of diluted sulphuric acid, and allow to stand for ten minutes, rotating the contents of the flask during this time to insure thorough mixing. Add 10 cc. of concentrated sulphuric acid in portions of about 2 cc., rotating the flask after each addition. When the reaction has ceased, add sufficient hydrogen dioxide T.S. to dissolve completely the brown precipitate (about 5 to 7 cc.). Toward the end of the reaction the hydrogen dioxide is to be added, drop by drop, to avoid any great excess. Dilute with 25 cc. of distilled water, and boil gently over an asbestos wire gauze for from fifteen to twenty minutes, or until the excess of hydrogen dioxide is expelled. Dilute with 50 cc. of distilled water, and add tenth-normal potassium permanganate until the liquid is faintly pink, then discharge the pink color by the addition of a drop of tenth-normal oxalic acid. Cool the solution, add 2.5 Gm. of potassium iodide, stopper the flask tightly, and allow it to stand in a cool, dark place for one hour. Then titrate the liberated iodine with tenth-normal sodium thiosulphate without the use of starch

indicator. Make a blank test with the same quantities of the reagents, and correct the assay for the volume of tenth-normal sodium thiosulphate used in the blank. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.003748 Gm. of As.

This assay is explained on page 1466.

Preserve in sealed containers of colorless glass, from which the air has been excluded either by the production of a vacuum or by displacement with a non-oxidizing gas.

Uses—Arsphenamine is useful as a specific remedy for syphilis in all stages.

The drug is used in the spirillum affections, such as relapsing fever, frambesia, and in malaria; it is also said to be an available substitute for arsenic in the treatment of diseases of the skin and nerves, and in the anemias.

It has been employed successfully in various types of syphilitic disease of the eyes. Repeated injections should be given.

Dose—From 3 to 6 grains (0.2 to 0.4 Gm.), though 9 grains (0.6 Gm.) may be given, but the smaller doses are being more extensively used.

For children from 3 to 5 grains (0.2 to 0.3 Gm.). In infants doses of from $\frac{1}{3}$ to $1\frac{1}{2}$ grains (0.02 to 0.1 Gm.) may be used. The dose should be varied according to the strength and condition of the patient. The intravenous method is, on the whole, preferable and is especially to be recommended.

Arsphenamine is sold under various trade names such as *arsenobenzol* (Powers-Weightman-Rosengarten Company), *diarsenol* (Diarsenol Laboratories, Inc.), and *salvarsan*, or "606" (H. A. Metz Laboratories, Inc.). The technic for the preparation of the solution is given below.

An aqueous 0.5 per cent solution of arsphenamine, possessing the proper degree of alkalinity is prepared by E. R. Squibb and Sons. It is supplied in ampuls of 80 cc. and 120 cc. These ampuls should not be used after the date stamped on the label of each package or if the color has changed from a light lemon or light wine color to dark green or a blackish tint. The uses are the same as those of arsphenamine.

Solution arsphenamine-Squibb is prepared by dissolving arsphenamine in freshly distilled water, carefully alkalinizing with sodium hydroxide solution and sealing in ampuls under a partial vacuum, the concentration being adjusted so that 100 cc. of solution represents 0.5 Gm. of arsphenamine.

Solution arsphenamine-Squibb is a clear yellow liquid which varies from a light lemon or light wine color to a greenish-yellow.

The Preparation of Arsphenamine Solutions

The following details for the preparation of arsphenamine solutions for injection have been copied, by permission, from a report of a board of medical officers representing the Army, Navy, and Public Health Service:[1]

I. *Method of injection.*

Only the gravity method should be employed in administering arsphenamine.

II. *Materials required.*

A. Erlenmeyer flasks, 500 to 1000 cc. capacity.
B. Funnels, glass, 4-inch.
C. Cylinders, graduated, 500 to 1000 cc. capacity.
D. Gravity apparatus, consisting of—

1. Gravity graduated glass cylinders, 300 cc. capacity; long graduations at the 100 cc. marks; medium long graduations every 25 cc.; short graduations for each 5 cc.; the zero point to be at the top and the 300 mark to be at the bottom of the cylinder.

2. Rubber tubing, pure gum, heavy wall, inside diameter, five thirty-seconds inch (about 4 mm.), of lengths to limit height of the cylinder to 3 feet above the patient's arm.

Caution.—Before being used the first time the tubing should be filled with normal sodium hydroxide solution for not less than six hours. It then should be rinsed thoroughly in water, sterilized by boiling, and then be rinsed carefully with sterile water again just before using.

3. Needles with slip joint, 19 standard gauge, medium bevel, length of cannula $1\frac{1}{2}$ inches. While not necessary, the Fordyce type of needle is a great convenience. The correct gauge is highly important, as it influences the rate of flow. Proper care of the needles is important. They should be cleaned immediately after use and precautions taken to prevent rust. Just before sterilization the point should be freshened on a stone, if necessary. A dull needle tends to make a dissatisfied patient.

4. Glass tubing 6 mm. in diameter, for windows, which should be inserted in the rubber tubing so as to be a few inches from the lower end.

[1] U. S. Naval Medical Bulletin, Nov., 1922, page 847.

5. Adapters for attaching needles to end of tubing. These may be of metal or glass. If of glass, they will serve as extra windows as well as adapters.

6. Pinchcocks (Mohr's) for cutting off the flow to be applied a short distance above the needle.

E. Sterile gauze, cut in small squares for filtering solution.

F. Sterile freshly distilled water. This water should be distilled in a glass or block tin and should be sterilized immediately by autoclaving or boiling in Erlenmeyer flasks. These flasks should be stoppered with a gauze-wrapped cotton plug and capped with paper or tin foil. Preparation of the water should preferably be carried out on the day before use so that it will be fresh and cool at the time needed.

G. Sterile Salt Solution. This should be made with water prepared as above and chemically pure sodium chloride. Sterilization should be carried out as given above. The strength of the salt solution should be the usual 0.85 per cent. The use of salt solution in the place of distilled water for the dilution is considered a refinement which is not necessary in routine work, but it may have some advantages, since a solution of arsphenamine in distilled water is not isotonic.

H. Normal sodium hydroxide volumetric solution (U. S. P.). Enough of this can be prepared at one time to last for a month or longer, provided it is kept in a rubber-stoppered wax or paraffin lined bottle. There is danger of deterioration on account of absorption of CO_2 from the air and of reactions with the glass container. A wax-lined bottle can be prepared by placing wax or paraffin in a bottle, melting it with dry heat, and spreading the melted wax by rotation over the inside of the bottle as it is cooling. If precipitate is found in the alkali, it is probably an evidence of deterioration of the solution, which should be discarded.

I. Burette or Pipette. A graduated burette or pipette for accurately measuring the alkali.

All glassware mentioned above should be of chemical standard. All apparatus should be surgically clean, freshly sterilized, and cool at time of using. The apparatus should be sterilized by dry heat or autoclave with the exception of the tubing and the needles, which should be boiled.

III. *Inspection of drug.*

A. Note and record manufacturer, lot number, and particularly the dosage stated on the label.

B. Examine the ampuls critically and do not use any which are cracked or in which the powder is not freely mobile and is not of a pale yellow to a lemon yellow in color. Forward any suspected ampuls, with explanatory letter, directly to the Hygienic Laboratory, Washington, D. C., for examination.

C. The ampuls, having satisfactorily passed preliminary inspection, should be immersed in 95 per cent alcohol primarily to detect any minute cracks in the glass not visible on preliminary inspection, and also to cleanse the ampul. Lay ampuls on sterile towel to dry, or wipe off alcohol with sterile gauze.

IV. *Preparation of solution.*

A. The amount to be prepared at one time will depend on the number of patients, but unit quantities or more than 10 average doses should not be prepared.

B. Place in Erlenmeyer flasks about 10 cc. of freshly distilled sterile water for each decigram of arsphenamine to be used, *e.g.*, 100 cc. for 1 Gm. Open the ampul and sprinkle the powder gently over the surface of the water. The temperature of the water is of great importance. For all brands of arsphenamine, except for arsenobenzol, manufactured by the Dermatological Research Institute, the water should be at room temperature and, as a rule, the drug should go into solution with little or no agitation within a few minutes. A slight amount of shaking is permissible with any product, but always should be kept at a minimum.

Exception—The arsphenamine manufactured by the Dermatological Research Institute requires either hot water alone, or it can be dissolved in cold water, if powder first is moistened thoroughly with ethyl alcohol (about 1 cc. to 0.6 Gm.). This amount of alcohol is harmless.

When the arsphenamine has completely dissolved, forming a perfectly clear solution with an absence of any gelatinous particle when viewed by transmitted light, it is ready for alkalinization. If for any reason the arsphenamine fails to form a perfect solution it must be discarded.

C. *Correct alkalinization* is extremely important; failure to alkalinize properly causes more reactions than any other error connected with the use of arsphenamine.

1. The exact method consists in the addition, all at once, of 0.85 cc. normal sodium hydroxide solution for each 0.1 Gm. of arsphenamine used, *e.g.*, 8.5 cc. for 1 Gm. of drug. This is the correct amount necessary to form the disodium salt of arsphenamine, the form which is best tolerated by the patient.

2. Approximate method of alkalinization. An exception to the rate that only standardized normal alkali should be used may be made in case this is not obtainable. Under such circumstances, the exact concentration of alkali being unknown, the operator should keep in mind the following facts: Arsphenamine as it appears on the market is the dihydrochloride of the arsphenamine base which is soluble in water, but the solution is strongly acid and highly toxic. Upon the gradual addition of sodium hydroxide, a precipitate at once begins to form and then redissolves. This property of the drug, not understood by some physicians, has caused them to mistake the end point. This mistake is especially apt to occur when the operator thinks he is using a 15 per cent solution, when in reality the solution is only 4 or 5 per cent. The drug when injected in this still strongly acid state, the monohydrochloride, produces serious reactions and sometimes death.

When a little over one-fourth of the amount of alkali indicated under (1) has been added, the precipitate no longer redissolves. From this point on until there has been added almost three-fourths of the amount of alkali necessary to form the disodium salt, the precipitate remains and does not redissolve on shaking. But when three-fourths of the total amount necessary has been added the precipitate redissolves.

It is at this point, when just enough alkali has been added to dissolve the precipitate, that the solution very frequently has been injected. *This solution of the monosodium salt is the most frequent cause of reactions.* At this point 75 per cent of the correct amount of sodium hydroxide solution has been added and hence an additional one-third of the total amount of alkali used up to this point should now be added. This last addition is the remaining 25 per cent of the correct amount corresponding to a total of 0.85 cc. per 0.1 Gm. of standardized N/1 NaOH solution as mentioned under (1) above; *e.g.*, if 3.3 cc. of an unknown solution were required for completely clearing a solution containing 2 Gm. of arsphenamine, 1.1 cc. more should be added. With a thorough understanding of the above the operator may roughly standardize his alkali against the arsphenamine. No two brands of arsphenamine vary greatly in the amount of alkali required, while various alkali solutions vary in strength by several hundred per cent.

The pH of a proper solution is about 10, and it is impossible to buffer it to neutrality by common buffers without precipitation. Moreover, the alkaline solution is well tolerated if given slowly and well diluted.

3. "Haphazard method" of alkalinization, or drop method. This is mentioned only to condemn it. It is inconceivable that the operator will be unable to secure some sort of a graduated measuring device in order to measure the alkali instead of guessing at the amount. Numerous reactions from under-alkalinization have occurred with this method, particularly where several doses of the drug are prepared at one time. The alkali has been added with a dropper until clearing occurred, and then a few additional drops have been added regardless of whether the solution contained 1 or 10 doses. Less frequently over-alkalinization also has occurred. The injection of an over-alkalinized solution causes pain along the veins and thrombosis.

D. *Filtration and dilution to proper strength of the alkalinized solution*—With sterile forceps place four layers of sterile gauze in the funnel. Wash with sterile water. Pour alkaline solution through into a graduated cylinder and then rinse the filter with enough sterile distilled water to bring the total for each decigram of drug up to 25 cc.; *e.g.*, for 1 Gm. of arsphenamine 250 cc. of solution should be made. This washing the drug through the filter with the water insures full dosage. If a saline solution is desired, it is used at this point in place of the distilled water, at usual strength, 0.85 per cent.

E. *Time the solution should be allowed to stand*—*The properly alkalinized, filtered, and diluted* solution now should stand for at least thirty minutes before being injected, to allow complete stabilization of the reactions. The toxicity is considerably reduced by this delay. The solution may stand as long as three hours without undergoing any increase in toxicity, provided it is protected from the air, not shaken, and provided the temperature does not exceed 30° C. The solution is now ready for administration.

F. *Temperature*—30° C. is the correct temperature at which the drug should be introduced; in no case should it be warmed above this point.

G. *Dosage*—As a rule the initial dose should be small. The average dose used is about 0.4 Gm. for 150 pounds body weight, but no hard and fast rule can be laid down; each case should be considered individually by the clinician. When a radical cure is being sought and the patient tolerates the injection well, full doses should be given.

NEOARSPHENAMINA. U. S. Neoarsphenamine

[Neoarsphen.]

Neoarsphenamine is a product obtained by the action of sodium methanal sulphoxylate on arsphenamine, and consists partially of sodium 3-diamino-4-dihydroxyarsenobenzene methanal sulphoxylate [$NH_2.OH.C_6H_3As : AsC_6H_3.OH.NH(CH_2O)OSNa = 466.17$]. It contains not less than 19 per cent of As, and complies with the requirements of the United States Public Health Service. A sample from each lot of Neoarsphenamine, produced by a manufacturer, must be submitted to the Hygienic Laboratory and approved before it may be marketed.

Neoarsphenamine is distributed in sealed containers of colorless glass, from which the air has been excluded either by the production of a vacuum or by displacement with a non-oxidizing gas.

Neoarsphenamine is prepared by treating the arsphenamine base with sodium formaldehyde sulphoxylate.

Description and Physical Properties—A yellow powder. It is odorless or has a slight odor. In the dry state or in solution it is readily oxidized by exposure to the air, becoming darker and more toxic. Higher temperatures accelerate the oxidation.

It is very soluble in water, soluble in glycerin, slightly soluble in alcohol and almost insoluble in acetone, chloroform, and in ether.

Tests for Identity—An aqueous solution of Neoarsphenamine (1 in 100) is neutral or slightly alkaline to litmus paper (*difference from arsphenamine*).

An aqueous solution of Neoarsphenamine (1 in 100) is precipitated by diluted mineral acids (*difference from arsphenamine*), but yields no precipitate with solutions of alkali hydroxides or carbonates, and is not precipitated by mercuric potassium iodide T.S. (*difference from arsphenamine*).

The addition of two drops of freshly prepared ferric chloride T.S. to 5 cc. of an aqueous solution of Neoarsphenamine (1 in 1000) produces a purple or purplish-red color, changing to dark red.

Add 3 cc. of silver nitrate T.S. to 5 cc. of an aqueous solution of Neoarsphenamine (1 in 100): a brown precipitate is immediately formed, rapidly becoming black (*difference from arsphenamine*).

To 10 cc. of an aqueous solution of Neoarsphenamine (1 in 100) add 10 cc. of diluted hydrochloric acid, and heat: the odor of sulphur dioxide is perceptible.

The solution resulting from the assay for arsphenamine directed below yields with hydrogen sulphide a yellow precipitate soluble in ammonium carbonate T.S.

Add 5 cc. of distilled water to 0.5 Gm. of Neoarsphenamine in a test tube, and gently agitate the mixture: a complete solution results in five minutes.

Assay—Proceed as directed under *Arsphenamine*.

Preserve in the original sealed tubes in a cool place, preferably not above 10° C.

Caution—Solutions of Neoarsphenamine must be freshly prepared when required for use and the drug should be of normal color and freely soluble. If not normal reject it.

Uses—Neoarsphenamine is a modified soluble compound of arsphenamine; its actions and uses are those of arsphenamine. It is given in larger doses than arsphenamine because it contains less arsenic and is less toxic. The average dose for men is 12 grains (0.75 Gm.), with 9 grains (0.6 Gm.) and 14 grains (0.9 Gm.) as the usual minimum and maximum doses. For women 9 grains

(0.6 Gm.) is the average with 7 grains (0.45 Gm.) and 12 grains (0.75 Gm.) as minimum and maximum. Children may be given from 2½ grains (0.15 Gm.) to 5 grains (0.3 Gm.).

Neoarsphenamine may be administered by intravenous or intramuscular injection, the former being considered decidedly preferable; it must not be administered subcutaneously. For intravenous injections, 12.5 cc. of freshly distilled water should be used for each 0.1 Gm. of neoarsphenamine. For the intramuscular injections, 3 cc. of freshly distilled water should be used for each 0.15 Gm. of neoarsphenamine, this yielding an approximately isotonic solution.

Neoarsphenamine may be employed intravenously in concentrated solutions. For this purpose as high as 0.1 Gm. may be dissolved in 0.5 cc. of sterile freshly distilled water; the injection is made with a syringe instead of by gravity.

Neoarsphenamine is also sold under various trade names such as *neodiarsenol* (Diarsenol Laboratories, Inc.), *neosalvarsan* (H. A. Metz Laboratories, Inc.), and *novarsenobenzol* (Powers-Weightman-Rosengarten Company).

The following description of its preparation for administration is copied, with permission, from a report of a board of medical officers representing the Army, Navy, and Public Health Service.[1]

I. *Method of injection of neoarsphenamine.*

The use of the gravity method is strongly recommended, especially in clinics where a considerable number of doses are to be given. It was demonstrated in one clinic that the average time required to give 100 injections was reduced, without changing the personnel, when the gravity method was substituted for the syringe method and a high percentage of reactions due directly or indirectly to the syringe method also ceased to occur. With the gravity apparatus arranged to deliver a dose in about four minutes, one operator was able to run two tables much more easily than one table with the syringe method.

It is recognized, however, that there are circumstances in which the syringe method is indicated, as in the field where apparatus must be reduced to a minimum. Under these circumstances the use of neoarsphenamine by the syringe method is a valuable therapeutic measure. It fills a need, but technically is inferior to the gravity method and therapeutically either method is inferior to arsphenamine given by the gravity method.

II. *Apparatus required.*

A. When the gravity method is to be used:

1. Gravity apparatus (see *Arsphenamine*, page 868).
2. Erlenmeyer flasks, 50 to 300 cc.
3. Funnels, glass, 2-inch.
4. Sterile gauze.
5. Graduated glass cylinders, 100 to 500 cc.
6. Sterile distilled water (see Arsphenamine).
7. Saline 0.85 per cent prepared as under Arsphenamine, page 870.

B. When syringe method is to be used:

1. 20 to 50 cc. all-glass syringes.
2. Rubber tubing, short, with adapters connecting syringe and needle.
3. Needles, 25 standard gauge, medium bevel.

III. *Inspection of drug.*

An even more critical examination should be made than in case of arsphenamine, as neoarsphenamine occasionally decomposes in the ampul, even when no cracks are present. The powder should be freely mobile and canary yellow to orange red in color. When it approaches a red color, is distinctly lumpy or solidified, do not use, but forward samples to the Hygienic Laboratory for examination.

Immerse in alcohol the ampuls which have passed inspection to further eliminate the presence of cracks and to clean the ampul.

IV. *Preparation of solution.*

A. *Amount to be prepared at one time*—In marked contrast to the practice with arsphenamine, do not prepare any more solution at one time than can be administered within 20 minutes.

B. *Concentration*—Preferably 1 decigram should be dissolved in 12.5 cc. of water. This solution is then twice as concentrated as an arsphenamine solution. Concentrations as high as 1 decigram in 0.5 cc. of water can be used in the field or under other special circumstances. The highly concentrated solutions, however, should be given very slowly.

C. *Solution.*

1. Put in Erlenmeyer flask 12.5 cc. sterile distilled water for each decigram of neoarsphenamine. In the field the concentrated solution can be made in the ampul itself by using water supplied in another ampul.

Caution—The distilled water used must be at room temperature and not to exceed 30° C.

2. Open the ampul and sprinkle the powder gently over the surface of the water and by preference allow it to go into solution with no agitation whatever. Slight rotation of the flask is permissible. *Shaking the solution increases its toxicity and should be avoided.*

[1] U. S. Naval Medical Bulletin, Nov., 1922, page 854.

In case the solution does not form a perfectly clear and transparent solution it should under no circumstances be used. Whether it requires 1 minute or 10 minutes for the drug to form a perfect solution is unimportant, but it should not require more than 10 minutes. The important point is not the rate of solubility but the complete solubility of the drug.

3. As soon as the neoarsphenamine is in solution filter through washed gauze into tall, narrow cylinders and keep stoppered. It is preferable to use a size of cylinder which the solution will nearly fill. The smaller the air column over the solution the less danger of increased toxicity. The solution is now ready to inject and, in marked contrast to the arsphenamine solution, which should stand at least 30 minutes before its injection, the neoarsphenamine solution should be injected immediately, and in no case shall it be allowed to stand longer than 20 minutes.

4. *Dose*—The initial dose as a rule should be small. The average dose is about 0.6 Gm. for 150 pounds body weight, but no attempts to lay down a hard and fast rule in this regard are made. The patient must be individualized.

Unofficial Arsenic Compounds

Silver Arsphenamine, N. N. R.—*Argentum Arsphenamina*—Sodium Silver Arsphenamine.—The sodium salt of silver-diamino-dihydroxy-arseno-benzene (the exact molecular formula has not been established). It contains approximately 20 per cent of arsenic and approximately 15 per cent of silver.

Silver arsphenamine is prepared by treating the dihydrochloride of 3-diamino-4-dihydroxy-1-arsenobenzene (arsphenamine) with silver salts, converting the resulting compound to the disodium salt, and precipitating by means of alcohol, ether or acetone. The silver is not in an ionizable form.

Silver arsphenamine is a brownish-black powder, unstable in air; when properly dried it is free from lumps. It is readily soluble in water, yielding a dark brown solution (*distinction from arsphenamine, sodium arsphenamine and neoarsphenamine*), the solution has an alkaline reaction (*distinction from arsphenamine*).

For further tests see the N. N. R.

Uses—Silver arsphenamine has practically the same uses as those of arsphenamine (see page 869). Its claimed advantage over other arsphenamine preparations is said to be due to the introduction of the silver (non-ionizable form) as a component, thereby improving the chemo-therapeutic index, presumably because of the fact that silver and its compounds have a decided antisyphilitic influence.

Dose—From 0.1 Gm. to 0.3 Gm. for adults. The treatment should begin with an injection of 0.1 Gm., gradually increasing the dosage, at intervals of not less than four days, to 0.2 Gm. maximum in women and 0.3 Gm. in men. The larger doses are only indicated if the preparation is well tolerated by the patient. The dosages 0.2 to 0.25 Gm. may be given at regular intervals of four days and repeated until the desired therapeutic results have been achieved. Patients with disorders of the nervous system or those suffering from severe headaches should be given smaller initial doses, 0.05 and 0.075 Gm. When these amounts are well tolerated, larger doses may be employed, increasing very gradually.

In preparing the solution for injection, the ampul is first sterilized by immersion in alcohol for fifteen minutes; after opening the ampul, the contents are sprinkled on the surface of 5 cc. of cool (20–22° C.), sterile, distilled water, contained in a small sterile flask. The silver arsphenamine will go into solution rapidly; heating and shaking must be avoided. A quantity of cool sterile solution of sodium chloride, 0.4 per cent, is then added so that the final solution will approximate 20 cc. of liquid per decigram (0.1 Gm.) of the drug. *The solution must be administered promptly.*

Manufactured by the H. A. Metz Laboratories.

Sodium Arsphenamine, N. N. R.—*Sodiarsphenamina*—Sodium Arsenphenolamine. The sodium of 3-diamino-4-dihydroxy-1-arsenobenzene, $NaO.NH_2C_3H_3As : As.C_2H_3NH_2ONa$, with a stabilizing medium. The arsenic content of 3 parts sodium arsphenamine is equivalent to 2 parts of arsphenamine.

Sodium arsphenamine is a bright yellow powder, very unstable in air; when properly dried, it is free from lumps. It is readily soluble in water, yielding an orange-yellow solution; the solution has an alkaline reaction (*distinction from arsphenamine*).

For further tests see the N. N. R.

Uses—The same as those of arsphenamine; its advantage over arsphenamine is that it does not require addition of alkali before use.

Dose—From 0.45 to 0.9 Gm. for adults. As 3 parts sodium arsphenamine are equivalent to 2 parts arsphenamine, the amount of drug to be administered should be 50 per cent more than arsphenamine under the same conditions. In preparing the solution for injection, the sodium arsphenamine must be dissolved immediately after opening the ampul and everything except gentle shaking should be avoided in effecting solution. The quantity of sterile distilled water used for solution should be in the proportion of 20 cc. for each 0.1 Gm. of the drug. Heating must be avoided in the preparation of the solution; any difficultly soluble preparation should not be employed. *The solution must be administered promptly.*

Manufactured by the Diarsenol Laboratories, Inc.

Sulpharsphenamine, N. N. R.—*Sulpharsphenamina.*—The salt, disodium 3,3-diamino-4, 4'-dihydroxyarsenobenzene-*N*-dimethylenesulphonate, $NaOSO_2.CH_2.NH.OH.C_6H_3.As : As.C_6H_3OH.NH.CH_2.O_2SONa$, with inert salt. The product has an arsenic content of from 19 to 24 per cent. According to claims, it differs from neoarsphenamine in having two side chains instead of one and in that the sulphur has a valence of four (with an extra oxygen atom) and not two as in neoarsphenamine.

Sulpharsphenamine is an orange-yellow powder possessing an odor resembling that of sulphur dioxide and arsine. It is readily soluble in water yielding a yellow solution which is acid to litmus (*distinction from neoarsphenamine which is neutral and sodium arsphenamine which is alkaline*). On standing overnight, the solution darkens and a precipitate is formed.

For further tests see the N. N. R.

Uses—The same as those of neoarsphenamine over which it is claimed to have the advantage of a higher chemotherapeutic index, more prolonged or delayed action, lower toxicity, a somewhat greater stability of solution in the presence of air, and of permitting subcutaneous injection.

Dose—For intramuscular or subcutaneous use the drug is dissolved in sterile, freshly distilled water in the proportion of about 0.1 Gm. to 0.3 cc.; for intravenous use a greater dilution is desirable, about 0.1 Gm. to 2 to 3 cc.

Solarson, N. N. R.—A 1 per cent solution of ammonium heptenchlorarsonate ($CH_3(CH_2)_4CCl : CH.AsO.OH.ONH_4$), rendered isotonic by the addition of sodium chloride. Solarson contains from 0.255 to 0.275 Gm. of arsenic (As) in 100 cc.

Uses—It is claimed that solarson has an advantage over the cacodylates, in that its arsenic is better utilized, and over the arsenilates in that subcutaneous and intramuscular injections produce less pain and are less liable to produce toxic effects.

Solarson is used as a means of obtaining arsenic effects in the treatment of anemia, chlorosis, malaria, neuroses and dermatoses.

Dose: from 1 to 2 cc. subcutaneously or intramuscularly.

Manufactured by the Bayer Company, Inc.

Stovarsol, N. N. R.—Acetylaminohydroxyphenylarsonic Acid—$HO.CH_3CONH.C_6H_3.As : O : (OH)_2$—The acetyl derivative of 3-amino-4-hydroxyphenyl-1-arsonic acid—Stovarsol contains from 27.1 to 27.4 per cent of arsenic (As).

Stovarsol is a white, odorless powder, having a slightly acid taste. It is slightly soluble in water and alcohol; readily soluble in solutions of alkalies or alkaline carbonates. It is stable at ordinary temperatures.

Uses—Stovarsol has been reported to produce favorable effects in the treatment of amebic dysentery. It is claimed to yield satisfactory results both in the eradication of dysenterial cysts and encysted flagellates, and for general amebic dysentery. Stovarsol is not proposed for the treatment of syphilis, and its use is in amebic infections.

Dose—Orally, 0.25 Gm. for adults; two or three doses a day for a period of seven days has been reported to give satisfactory results.

Manufactured by Powers-Weightman-Rosengarten Company.

Tryparsamide, N. N. R.—Sodium N-phenylglycinamide-*p*-arsonate — $(NH_2COCH_2NH).C_6H_4.(AsO.OH.ONa)_2.H_2O$—Tryparsamide contains 24.6 per cent of arsenic in organic combination.

A colorless, odorless, crystalline powder (*distinction from arsphenamine compounds*). It is freely soluble in water, forming a solution neutral to litmus. It is insoluble or only slightly soluble in alcohol, ether, chloroform, and benzene.

Uses—Tryparsamide is primarily a trypanocidal agent and is proposed for use in the treatment of certain forms of trypanosomiasis (African sleeping sickness and *mal de caderas*). In the case of human trypanosomiasis due to T. gambiense it is relatively easy to sterilize the peripheral blood by a single dose of the drug, but relapses are likely to occur unless the treatment is continued for some time.

Dose—From 0.5 to 3.0 Gm. for adults, depending on the purpose for which the drug is used. In general, the dose should not exceed 0.04 to 0.05 Gm. per kilogram of body weight, and such doses should not be repeated at intervals of less than one week. Tryparsamide may be administered subcutaneously, intramuscularly or intravenously, though the intravenous administration is generally employed. The drug is dissolved in sterile water or physiological solution of sodium chloride. Tryparsamide should never be administered by mouth.

Manufactured by Powers-Weightman-Rosengarten Company.

Unofficial Antimony Compounds

Antimony Thioglycollamide, N. N. R.—The triamide of antimony thioglycollic acid $Sb(S.CH_2CO.NH_2)_3$. It contains not less than 30 per cent of antimony.

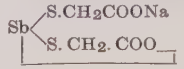
A white, crystalline, odorless powder. It is soluble in about 200 parts of water; somewhat soluble in alcohol; insoluble in ether.

Uses—Suggested for the treatment of human trypanosomiasis and in trypanosomic diseases of the larger animals. In the doses employed they were less toxic and less irritating than tartar emetic and the results obtained were decidedly more favorable.

Dose—The usual intramuscular or intravenous dose employed by Randall is 0.08 Gm., dissolved in 20 cc. of sterile water every second day until from 15 to 25 injections had been given. He recommends that at least 12 injections be given after the first healing has taken place to insure permanent cure. Its solutions are incompatible with solutions of the fixed alkalies.

Manufactured by Hynson, Westcott and Dunning.

Antimony Sodium Thioglycollate, N. N. R.—The compound formed by dissolving antimony trioxide in a solution of a mixture of sodium thioglycollate and thioglycollic acid.



It contains not less than 37 per cent of antimony.

A white or faintly pinkish powder; odorless or having a faint odor of mercaptan; very soluble in water; insoluble in alcohol.

Uses—The same as antimony thioglycollamide. It is more soluble than antimony thioglycollamide, and in higher dosages it appears to be less toxic.

Dose—From 1 to 2 grains (0.05 to 0.1 Gm.) dissolved in 10 to 20 cc. of sterile water every third or fourth day until from 15 to 25 injections have been given. Its solutions are incompatible with solutions of the fixed alkalis.

Manufactured by Hynson, Westcott and Dunning.

ORGANIC-SILVER COMPOUNDS

ARGENTO-PROTEINUM FORTE. U. S. Strong Silver-Protein

[**Arg.-Prot. Fort.**—STRONG PROTARGIN]

A compound of silver and protein, containing not less than 7.5 and not more than 8.5 per cent of silver (Ag).

In colloidal silver preparations, the silver does not exist, at least to any great extent, as free ions; therefore, it does not precipitate chlorides or proteins, and is noncorrosive, and, relatively or quite, nonastringent and nonirritant. Nevertheless, a considerable degree of antiseptic action is retained. This is not proportional to the total silver content, and varies for the different compounds; suggesting that the antiseptic action is due to the liberation of very low concentrations of silver ions, which vary for the different compounds.

Description and Physical Properties—A brown, odorless powder, usually somewhat hygroscopic.

Strong Silver-Protein is freely soluble in water, but almost insoluble in alcohol, chloroform, and ether.

Tests for Identity—Heat about 0.2 Gm. of Strong Silver-Protein in a porcelain crucible until all carbonaceous matter is burned off, warm the residue with 1 cc. of nitric acid, dilute with 10 cc. of distilled water, and add hydrochloric acid: a white precipitate is produced which dissolves in ammonia T.S.

The addition of 2 cc. of a 1 per cent aqueous solution of sodium chloride to 10 cc. of an aqueous solution of Strong Silver-Protein (1 in 100) causes no turbidity.

Ferric chloride T.S. added to its aqueous solution (1 in 100) discharges the dark color, and a precipitate is gradually produced. With mercuric chloride T.S. a white precipitate is formed, and the supernatant liquid becomes colorless or nearly so.

When tested by the method described below, Strong Silver-Protein permits abundant gas formation when 0.6 cc. of its aqueous solution (1 in 200) is added to 20 cc. of the yeast-sugar mixture, and at most only one bubble of gas is formed when 1.5 cc. of the same strength solution is added to 20 cc. of the yeast-sugar mixture. If the yeast is more active, as determined by the control with silver nitrate described below, a proportionately larger volume of the Strong Silver-Protein solution is required, or if the yeast is less active, a proportionately smaller volume of the Strong Silver-Protein solution is required.

Triturate an aqueous solution of sucrose (1 in 10) with 4 per cent of its weight of compressed yeast. Place four 20 cc. portions of this mixture in test tubes. To one test tube add 0.6 cc. of an aqueous solution of Strong Silver-Protein (1 in 200), mix well, immediately fill a small test tube with this mixture and invert it into the larger test tube, being careful that no air bubbles rise into the small test tube. To the second test tube add 1.5 cc. of an aqueous solution of Strong Silver-Protein of the same concentration; to the third tube add 0.6 cc. of an aqueous solution of silver nitrate (1 in 2000), and to the fourth tube add 1 cc. of the same silver nitrate solution. Fill smaller test tubes with each solution and proceed as directed for the first tube. Place all four of the test tubes in a bath at 38° C. and maintain this temperature for one hour. At the end of this period, the first and third of the smaller tubes should show abundant gas formation, the second smaller tube should show not more than a bubble of gas, and the fourth tube should show not more than about 1 cc. of gas. If the third tube shows no gas, repeat the tests reducing the concentration of all of the silver solutions to one-half, and if there should still be no gas formation in the third tube, again repeat the tests, reducing the concentration of all of the silver solutions by one-third. If the fourth tube in the first series of tests contains more than about 1 cc. of gas, repeat the tests, but increase the concentration of all of the silver solutions by one-third, and if this also produces more than 1 cc. of gas in the fourth tube, again repeat the tests, increasing the concentration of all of the silver solutions by one-half (*distinction from Mild Silver-Protein*).

Assay—Ignite about 2 Gm. of Strong Silver-Protein, accurately weighed in a porcelain crucible until all of the carbon is burned off. Transfer as much as possible of the residue to a beaker, add to the crucible 5 cc. of nitric acid, warm to dissolve any adhering silver, and transfer the solution to the beaker with the aid of a little distilled water. Cover the beaker, and heat on a water bath until all of the metallic silver is dissolved, adding a little more nitric acid, if necessary. Filter into a flask, wash the insoluble residue thoroughly with distilled water, cool, and dilute with distilled water, if necessary, to about 50 to 75 cc. Add 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01079 Gm. of silver.

This assay is explained on page 1462.

Preserve in well-closed containers, protected from light.

Caution—Solutions of Strong Silver-Protein should be freshly prepared and dispensed in amber-colored bottles.

Uses—The colloidal silver compounds are used mainly on mucous membranes, for antiseptic and germicidal effects. The strong silver-protein, or *protargin strong*, group is most effective in this respect, but is slightly irritant and stimulant. The *protargin mild* group acts also largely as a mucilaginous demulcent and protective; and as a detergent, by dislodging pus. Collargol acts locally like the mild silver-protein group, but is used mainly to produce systemic reactions.

The commercial preparations are for the most part produced by dissolving reduced silver or silver oxide, or some protein-silver precipitate, in an excess of a denatured protein, and drying *in vacuo*. This results in substances that dissolve very freely, although somewhat slowly, in water, yielding brown " colloid solutions " which contain so little of free silver ions that they do not readily precipitate chlorides or proteins. They consist of probably indefinite mixtures of metallic silver, silver oxide, and various silver-protein compounds, all in colloidal form. The proportions of these and the properties of the mixture vary according to the conditions under which they are produced. Although there are probably all kinds of gradations, most of the products on the market fall into a small number of fairly definite therapeutic groups:

(A) Strong Silver-Protein or Protargol Type.
(B) Mild Silver-Protein or Argyrol Type.
(C) Collargol Type.
(D) Electric Type.

The Strong Silver-Protein compounds contain the lowest percentage of silver (from 7 to 8.5 per cent), but have the strongest germicidal action, and are distinctly irritant. They are, therefore, therapeutically intermediate between silver nitrate and protargin mild. The following products belong to this group: *proganol*, *protargentum-Squibb*, and *protargol*.

The Mild Silver-Protein compounds contain from 19 to 30 per cent of silver, but are quite nonirritant. The following products belong to this group: *argyn*, *argyrol*, *cargentos*, *silvol*, *solorgentum-Squibb*, and *vargol*.

Collargol type contains a much higher percentage (78) of silver, said to be in the form of metallic silver, reduced to the colloidal form by chemical means, and " stabilized " by " a small percentage of egg albumin with products of oxidation". However, the albumin is denatured, since it does not precipitate on boiling; and it presumably constitutes the greater part of the 22 per cent that is not silver. Collargol, therefore, seems to differ from the preceding class in degree rather than in principle, containing a larger proportion of silver in the form of colloidal-metal and oxide, and a smaller proportion in the form of proteinate. Its therapeutic field has been somewhat different, namely, for intravenous and intramuscular injection.

In the *electric type* of silver compounds metallic silver is brought into colloidal solution electrically, *i. e.*, by forming an arc between silver electrodes under water. These solutions are, however, very dilute, and are not sufficiently stable for concentration. They are also likely to contain silver oxide, and sometimes ionized silver.

Dose—The concentrations for mucous membranes range from 0.1 to 10 per cent for strong silver-protein, from 5 to 50 per cent for mild silver-protein, and from 0.02 to 1 per cent for collargol. These are applied every two to four hours, if possible. Solutions should be recently prepared, and should be protected against light. Ointments and suppositories are used with the same concentrations as the aqueous solutions. Stains on linen are removed by a 1 in 1000 solution of mercuric chloride. Solutions are best prepared by dusting the powder on the surface of cold water, and allowing it to dissolve without stirring or shaking. This requires about ten minutes.

ARGENTO-PROTEINUM MITE. U.S. Mild Silver-Protein

[**Arg.-Prot. Mit.**—MILD PROTARGIN]

Silver rendered colloidal by the presence of or combination with protein. It contains not less than 19 per cent and not more than 25 per cent of silver (Ag).

The preparation and characteristics of Mild Silver-Protein are discussed under Strong Silver-Protein (see page 875).

Description and Physical Properties—Dark brown or almost black, shining scales or granules. It is odorless, and is frequently hygroscopic.

Mild Silver-Protein is freely soluble in water, but almost insoluble in alcohol, chloroform, and ether.

Tests for Identity—Heat about 0.1 Gm. of Mild Silver-Protein in a porcelain crucible until all carbonaceous matter is burned off, warm the residue with 1 cc. of nitric acid, dilute with 10 cc. of distilled water, and add hydrochloric acid: a white precipitate is produced which dissolves in ammonia T.S.

The addition of 2 cc. of an aqueous solution of sodium chloride (1 in 100) to 10 cc. of an aqueous solution of Mild Silver-Protein (1 in 100) causes no turbidity.

Ferric chloride T.S. added to its aqueous solution (1 in 100) discharges the dark color and a precipitate is gradually produced. With mercuric chloride T.S. a white precipitate is formed and the supernatant liquid becomes colorless or nearly so.

When tested by the method described under *Argento-Proteinum Fortius*, 0.8 cc. of an aqueous solution of Mild Silver-Protein (1 in 20) permits abundant gas formation (distinction from *Strong Silver-Protein*).

Assay—Proceed as directed under *Argento-Proteinum Fortius*, using about 1 Gm. of Mild Silver-Protein.

Preserve in well-closed containers, protected from light.

Caution—Solutions of Mild Silver-Protein should be freshly prepared and dispensed in amber-colored bottles.

Uses—See Strong Silver-Protein, page 875.

Other Colloidal Silver Compounds

Collargol, N. N. R.—*Collargolum*—Colloidal Silver—Argentum Colloidale—Argentum Credé—Colloidal silver and silver oxide, formed by reduction and stabilized by derived egg-albumin, with which it is possibly partly combined. It contains silver equivalent to approximately 78 per cent metallic silver of which about 2 per cent is ionized. It forms, with water, a fairly stable colloidal suspension.

Small, hard, brittle, bluish-black scales. With 20 parts of distilled water, it forms a colloidal suspension, black in incident light, and reddish-brown in transmitted light, which remains stable for months. The addition of albumin to collargol prevents or delays its precipitation by acids and salts. A sufficient amount of albumin to prevent its precipitation under ordinary conditions is, therefore, added to collargol during its manufacture. Hence, collargol, even when added to spring or well-water containing salts, undergoes no change. Whereas, colloidal silver containing no albumin precipitates on being boiled. Collargol solutions brought once to the boiling point present no macroscopic changes, though they do decrease in stability.

Uses—The intravenous injection of collargol is followed, after from two to four hours, by a chill, fever and leukocytosis. This reaction has been used, with variable results, against general and localized infections, similar to nonspecific protein therapy. Indeed, it is possible that the protein stabilizer may play the principal or sole part in the reaction. The direct antiseptic action is rather feeble, and probably due to contamination with free silver ions.

Dose—It is employed in carefully filtered solutions (colloidal suspensions) varying in strength according to the intended use; from 10 to 20 cc. of a 2 per cent solution for intravenous injections (the possible reaction of certain persons to egg protein should be considered); and from 0.02 to 1 per cent solution for washes. Collargol solution should not be sterilized by boiling, but sterile solution mediums should be used. Locally, it is used in the form of a 15 per cent ointment, from 30 to 60 grains (2 to 4 Gm.) being very thoroughly rubbed into the skin; in the form of 5 per cent dusting powder, prepared with finest clay; of bougies containing 3 grains (0.2 Gm.), and vaginal suppositories and tampons each containing ¾ grain (0.05 Gm.); for parenchymatous injections in from 0.5 to 1 per cent glycerin solutions. Internally, a solution (colloidal suspension) of from 1 in 500 to 1 in 100 is given freely in teaspoonful doses added to the food, in infectious gastric and intestinal diseases. It is also given in tablets, containing 1 grain (0.06 Gm.).

Collargol ointment is prepared by incorporating 15 parts of collargol with 5 parts of water, 10 parts of white wax, and 70 parts of benzoinated lard, taking care that the soluble silver shall not be transformed into metallic silver of the ordinary kind. This, it is asserted, is liable to occur unless great care is observed in the manipulation.

The natural color of collargol ointment is reddish-brown. The ointment is good as long as it colors the skin black.

Manufactured by the Heyden Chemical Company of America, Inc.

Lunosol, N. N. R.—*Argenti Chloridum Colloidale Saccharatum-Hille*—A preparation of colloidal silver chloride containing silver chloride, 10 per cent, and sucrose, 90 per cent.

A white, slightly hygroscopic, granular powder, odorless, having a sweetish, metallic taste. It is completely soluble in one half of its weight of water, forming an opalescent solution (colloidal suspension) which is bluish white in reflected light and reddish in transmitted light.

Uses—Lunosol has antiseptic and germicidal properties. It causes neither irritation of the mucous membranes nor coagulation of albumin even in concentrated solutions; it does not stain the skin.

Lunosol is intended for the prophylaxis against and treatment of infections of the accessible mucous membranes, such as the genito-urinary tract and the eye, ear, nose and throat.

Dose—It is generally used in solutions (colloidal suspensions) of from 1 to 25 per cent. In the male urethra, from 3 to 25 per cent solutions are used; for irrigation of the vagina, a 1 per cent solution is used, and on tampons, a 10 per cent solution; for irrigation of the bladder, a 0.1 to 1 per cent solution, and for irrigation of the rectum, a 1 to 5 per cent solution is used; in ophthalmia neonatorum, 25 to 50 per cent solutions are applied; in pyelitis, 3 to 10 per cent solutions are injected into the kidney pelvis; for application to the nose, eye and ear, the average concentration is 10 per cent.

Manufactured by Hille Laboratories, Inc.

Neo-Silvol, N. N. R.—Colloidal silver iodide compound—A compound of silver iodide with a soluble gelatin base containing 18 to 22 per cent of silver iodide in colloidal form.

Pale yellow granules. In concentration up to 50 per cent neo-silvol forms with water almost colorless, milky or opalescent solutions (colloidal suspensions). Neo-silvol is insoluble in fixed oils, but slowly soluble in glycerin. Solutions of neo-silvol are not precipitated in the cold by strong acids or sodium chloride.

Uses—Neo-Silvol, even in concentrated solutions, causes neither irritation of mucous membrane nor coagulation of albumin. It does not stain the skin.

It is claimed that neo-silvol in laboratory tests for germicidal value has been found as effective as phenol in its action on bacteria.

Neo-silvol is intended for the prophylaxis against, and treatment of infections of accessible mucous membranes and is claimed to be indicated in infections of the genito-urinary tract and of the eye, ear, nose and throat.

Dose—In the treatment of acute inflammations of the mucous membranes solutions of neo-silvol as strong as 50 per cent may be used. In inflammatory infections of the ear, nose and throat, 5 to 40 per cent solutions are used; for irrigating sinuses 2 to 5 per cent; for inflammatory conditions of the eye and conjunctival infections in strength of 10 to 40 per cent; in acute anterior urethritis, as an abortive measure, 20 per cent; for posterior urethritis or in the routine treatment of anterior urethritis, 10 per cent; in the genito-urinary tract of the female, from 10 to 50 per cent.

Solutions of neo-silvol are prepared by adding the substance to the required amount of water and agitating the mixture until solution occurs.

Manufactured by Parke, Davis and Company.

Unofficial Organic Mercury Compounds

The early methods of administering mercury were by mouth and by inunction. The oral method continues to be popular, but often causes troublesome gastro-intestinal symptoms. The inunction method obviates the digestive disturbances; but the amount of the drug absorbed cannot be well controlled, and it is often practically impossible to introduce an amount sufficient for syphilis.

In more recent years, the attempt to improve mercurial therapy has been mainly along two lines: the perfection of intramuscular usage and the introduction of the organic compounds.

The original practice of injecting mercuric chloride has not gained a wide endorsement because of the pain inflicted and because the necessity of daily injections was difficult to meet. It has been found that the pain is considerably lessened by the use of mercury combined with the amino-acids and their derivatives such as the succinimide.

The employment of mercurial salts that are less soluble than the bichloride has enabled the physician to give injections at longer intervals and still ensure a daily absorption of the drug. These insoluble preparations, such as the salicylate and the benzoate, are injected into the muscle, but they are accompanied by no little pain.

The organic compounds of mercury, such as mercurol, are said to be less irritating to the gastro-intestinal tract than the inorganic salts. Further experience will be necessary to determine their real value.

Compounds of mercury are also used for preparation of antiseptic and germicidal solutions.

MERCURIC COMPOUNDS

Flumerin—(H. W. & D.), N. N. R.—Disodium-2-hydroxymercurifluorescein, $NaOOC.C_6H_4.C.C_6H_2.HgOH.ONa.C_6H_3O$. The disodium salt of 2-hydroxymercurifluorescein.

A red, odorless powder; somewhat hygroscopic. It is soluble in hot water (about 1 : 10); insoluble in alcohol, chloroform or ether. On incineration flumerin-H. W. & D. yields an ash containing sodium carbonate. Aqueous solutions of flumerin-H. W. & D. are deep orange-red in strong concentrations, but show a greenish-red fluorescence in very dilute solutions, the fluorescence being less intense than that of fluorescein in the same concentration. Aqueous solutions of flumerin-H. W. & D. are decomposed by acids, chlorides, bromides iodides and the salts of many alkaloids, and local anesthetics.

Uses—Flumerin-H. W. D., when injected intravenously, causes the disappearance of spirochetes from primary and secondary syphilitic lesions and will bring about resolution of the lesions and in about one-half the cases it will change a positive blood Wassermann reaction to negative, according to various reports.

Dose—From 0.002 to 0.005 Gm. per kilogram of body weight injected intravenously in 2 per cent aqueous solution. Flumerin-H. W. & D. is incompatible with acids, halides and the salts of many alkaloids. Therefore water and not physiologic solution of sodium chloride is used to prepare solutions. If solutions be made with sterile water they may be used during three days if kept in well-stoppered bottles in the dark.

Manufactured by Hynson, Westcott & Dunning.

Flumerin-H. W. & D. Tubes, 0.15 *Gm.*
Flumerin-H. W. & D. Tubes, 0.20 *Gm.*
Flumerin-H. W. & D. Tubes, 0.25 *Gm.*
Flumerin-H. W. & D. Tubes, 0.30 *Gm.*

Mercurialized Serum, N. N. R.—A solution of mercuric chloride in normal horse serum diluted with physiologic solution of sodium chloride. It is prepared by the method of C. M. Byrnes (*J. A. M. A.*, **63** : 2182 [Dec. 19] 1914).

Uses—Mercurialized serum is proposed for the treatment of syphilis, particularly of the cerebrospinal type. This is an attempt to produce a preparation which, while therapeutically active, is noncorrosive, has a low toxicity and slight local irritative action, does not coagulate serum albumin, and which consequently is adapted to intraspinal use and can be used intravenously without danger of phlebitis.

Dose—Intraspinally, 30 cc. of a solution, the dose containing the equivalent of $\frac{1}{20}$ grain (0.0013 Gm.) of mercuric chloride, after *first* withdrawing sufficient spinal fluid to reduce the pressure to 30 mm. (water). The dose may be increased, when tolerance is established, to 30 cc. of a stronger solution, the dose containing the equivalent of $\frac{1}{25}$ grain (0.0026 Gm.) of mercuric chloride. Intravenously, 2 cc. of solution, the dose containing the equivalent of $\frac{1}{12}$ grain (0.0055 Gm.) of mercuric chloride.

Mercuric Benzoate, N. N. R.—*Hydrargyri Benzoas*—Hydrargyrum Benzoicum.—$Hg(C_3H_5COO)_2 + H_2O$. The mereuric salt of benzoic acid.

A white, crystalline powder; slightly soluble in water, yielding a weakly acid solution; more soluble in an aqueous sodium chloride solution. It is insoluble in alcohol or ether. At 20° C., a 10 per cent solution of sodium benzoate dissolves 1 per cent of its weight of mercuric benzoate. With alcohol mercuric benzoate is decomposed into a basic salt having a yellow color.

Uses—The same as those of mercuric chloride.

Dose—Mercuric benzoate is used for intramuscular injections in syphilis and in treating gonorrhea. In urethral cases, the solution may be 1 : 2000 or 1 : 1000 with an equal quantity of sodium chloride. For intramuscular injection, mercuric benzoate is given in a 1 per cent solution by dissolving 0.3 Gm. of mercuric benzoate in 30 cc. of water, containing 1.5 Gm. of ammonium benzoate or given in 2 per cent solution with 2.5 per cent of sodium chloride, the average dose being about 24 or 12 minims, respectively ¼ grain (0.015 Gm.), every second day.

Prepared by Swan-Myers Company and the Intra Products Company, Denver.

Mercuric Cyanide, N. N. R.—*Hydrargyri Cyanidum*—Hydrargyrum Cyanatum—$Hg(CN)_2$—The mercuric salt of hydrocyanic acid.

In colorless or white, prismatic crystals, or white powder, odorless and having a bitter, metallic taste the salt is exceedingly poisonous). It is darkened on exposure to light; is soluble at 15° C. in 12.8 parts of water and in 15 parts of alcohol, in 3 parts of boiling water and in 6 parts of boiling alcohol, and is very sparingly soluble in ether.

Uses—Mercuric cyanide has been reported to be as actively antiseptic as mercuric chloride and to be less irritating; but this has been questioned. It is used locally and internally like mercuric chloride.

Dose—Internally, from $\frac{1}{12}$ to $\frac{1}{8}$ grain (0.004 to 0.008 Gm.); locally, solutions of from 1 : 4000 to 1 : 2000 may be used for applications to the eye or mucous membranes; from 25 to 35 minims of a 1 per cent solution may be used hypodermically without causing local irritation. Death has occurred from the use of a vaginal injection containing 0.9 Gm. (14 grains) of mercuric cyanide.

In diphtheria and croup, it is used in 0.01 per cent solution as a gargle or internally in doses of from 0.0077 to 0.0154 grain (0.0005 Gm. to 0.001 Gm.). In fibrinous rhinitis it is used on a tampon in 0.04 per cent solution.

Mercuric Oxycyanide, N. N. R.—*Hydrargyri Oxycyanidum*—Hydrargyrum Oxycyanatum—$Hg(CN)_2 HgO$—A basic mercuric salt of hydrocyanic acid, containing from 51.7 to 56.0 per cent of mercuric cyanide $[Hg(CN)_2]$ and from 44.3 to 48.0 per cent of mercuric oxide (HgO).

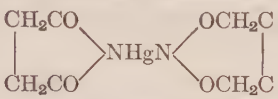
A white, or nearly white, microcrystalline powder, soluble in about 80 parts of water, yielding a solution alkaline to litmus.

Uses—Mercuric oxycyanide has been proposed as a substitute for mercuric chloride. Its antiseptic power is claimed to be greater and it is asserted to be less irritating than mercuric chloride because it does not act on albumin to the same extent. It has the advantage over mercuric chloride in that it does not corrode steel instruments.

Dose—Mercuric oxycyanide may be administered in the same doses as mercuric chloride. It may be applied locally in solutions of 1 : 5000 or somewhat stronger.

Prepared by the Gradwohl Laboratories, St. Louis.

Mercuric Succinimide, N. N. R.—*Hydrargyri Succinimidum*—$Hg[(CH_2.CO)_2N]_2$—The mercuric salt of succinic acidimide,



A white, crystalline powder; soluble in about 10 parts of cold water; soluble in about 5 parts of boiling water, and in 300 parts of alcohol. It is very stable in solution. The aqueous solution is not affected by albumin. Mercuric succinimide should be protected from light.

Uses—Mercuric succinimide has the action of other salts of mercury, but its solutions are said to be relatively non-irritating. The preparation is used like other compounds of mercury in the treatment of syphilis.

Dose—Mercuric succinimide is used mainly by hypodermic injection. The daily hypodermic dose is from ⅙ to ⅓ grain (0.01 to 0.02 Gm.) given in the form of a 2.5 per cent solution (from 8 to 16 minims (0.5 to 1 cc.) of such solution)—Mercuric succinimide may be given by the mouth in doses of from ⅙ to ¼ grain (0.01 to 0.15 Gm.).

Mercurochrome-220 Soluble, N. N. R.—$NaOOC.C_6H_4.C{:}C_6H_2Br{:}O.C_6HBr(ONa)(HgOH).3H_2O$.

—The disodium salt of 2 : 7-dibromo-4-hydroxymercurifluorescein, containing 23 to 24 per cent of mercury.

Mercurochrome-220 soluble occurs as iridescent, green scales or granules; odorless; permanent in the air. It is freely soluble in water; soluble in 65 parts of alcohol; insoluble in chloroform or ether.

Uses—Mercurochrome-220 soluble is a strong and rapidly acting germicide; it is active in urine, a 1 : 1000 solution killing *Bacillus coli* and *Staphylococcus aureus* in this medium in one minute. It penetrates the tissues readily. The drug is tolerated in a strength of 1 per cent by the bladder, renal pelvis and urethra; a 2.5 per cent solution applied to the anterior urethra causes only temporary discomfort. No systemic effects have been observed following its local application in the human. Mercurochrome-220 soluble has been used in cystitis and urethritis and in chancroidal ulcerations; also in affections of the eye and ear, such as ophthalmia neonatorum and otitis media. The drug has also been injected intravenously in the treatment of septicemias and of local infections (subcutaneous abscesses following severe injury, retroperitoneal abscess following bladder instrumentation, etc.). The drug seems to be particularly active against organisms of the colon group; although it has seemed to give good results in some cases of staphylococcus and streptococcus septicemia, it is often times without effect. The intravenous injection is usually but not invariably followed by a transient increase of temperature and vomiting and sometimes by a severe diarrhea.

Dose—A 1 per cent aqueous solution is used for bladder injections. In the treatment of acute anterior gonorrhea, a 2.5 per cent solution is used every three hours. In chancroidal ulcerations, the drug is applied as a moist dressing (1 per cent), or as a starch paste (5 per cent), or as an ointment (5 per cent). In ophthalmia neonatorum a 2.5 per cent solution is freely instilled in each eye several times a day. The dose by intravenous injection has usually been 0.005 Gm. per kilo of body weight. This dosage is administered in a one per cent solution, freshly prepared from recently distilled water and filtered before using. Solutions are self-sterilizing and should not be boiled. They should be made up from the drug itself, as the tablets are not suitable for this purpose.

Mercurochome-220 soluble is incompatible with acids, with the salts of most alkaloids and with most local anesthetics. The aqueous solution stains the skin red but the discoloration may be removed by a washing in a solution of sodium hypochlorite (solution of chlorinated soda).

Manufactured by Hynson, Westcott and Dunning.

Mercurol, N. N. R.—*Hydrargyri Nucleinas*—Mercury Nucleinate—An organic compound of mercury with nucleinic acid from yeast, containing 20 per cent of metallic mercury.

A brownish-white powder, soluble in water, especially in warm water, insoluble in alcohol. Its watery solution has a distinct metallic taste, a weak alkaline reaction, and is not precipitated by alkalies, nor by albuminous liquids.

The mercury in this preparation resists the action of hydrogen sulphide to a marked degree.

Uses—Mercurol does not coagulate albumin; it has marked bactericidal power and possesses the pharmacologic action of soluble mercury compounds.

It is said to be useful as a local antiseptic application and as an antisyphilitic remedy.

Dose—From ½ to 2 grains (0.03 to 0.12 Gm.).

Manufactured by Parke, Davis and Company.

Mercurosal, N. N. R.—Disodiumhydroxymercurisalicyloxyacetate—$(HOHg).NaOOC.C_6H_3.OCH_2COONa$—Mercurosal contains from 43.0 to 43.8 per cent of mercury in organic combination.

A white, amorphous powder. It is soluble in about 10 parts of water, insoluble in the usual organic solvents. Dilute aqueous solutions of mercurosal are quite stable when protected from air, but on prolonged standing may give rise to an insoluble compound. Mercurosal is decomposed by acids, strong reducing agents; salts of heavy metals, such as silver or lead, yield insoluble precipitates. From a 1 to 2 per cent aqueous solution of mercurosal, calcium chloride precipitates a calcium salt which dissolves on subsequent dilution with water. Mercurosal is faintly alkaline to phenolphthalein solution.

Uses—It is claimed that mercurosal is relatively free from irritant action, that it is eliminated without untoward effect on the kidney and that its toxicity is relatively lower than mercuric chloride and mercuric salicylate. Mercurosal is intended for the mercurial treatment of syphilis. It is administered either intramuscularly or intravenously.

Dose—The usual intramuscular dose is 0.05 Gm. dissolved in 2 cc. of sterile water, every fourth or fifth day for ten or twelve doses. The usual intravenous dose is 0.1 Gm. dissolved in 5 cc. of sterile water administered every second or third day for ten to twelve doses.

Manufactured by Parke, Davis and Company.

Mergal, N. N. R.—A mixture of 1 part of mercuric cholate and 2 parts of albumin tannate put up in capsules. Each capsule is said to contain approximately 2¼ grains (0.15 Gm.) of mergal, equivalent to ¾ grain (0.05 Gm.) of mercuric cholate and 1½ grains (0.1 Gm.) of albumin tannate. Mergal contains approximately 4.4 per cent of mercury.

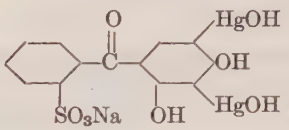
A yellowish-white, loose, somewhat light powder, insoluble in water and alcohol and almost insoluble in solution of sodium chloride.

Uses—Mergal is said to pass through the stomach without decomposition and to be decomposed into its constituents in the small intestine, where the mercury is quickly absorbed into the blood and excreted through the kidneys. It is said to be useful in all forms of syphilis and in the so-called parasyphilitic affections, such as tabes and general paralysis.

Dose—Onc capsule three times a day after meals, gradually increasing to two capsules, five or six times a day.

Manufactured by Riedel and Company, Brooklyn.

Meroxyl, N. N. R.—A mixture containing approximately 50 per cent of the sodium salt of 2,4-dihydroxy-3,5-dihydroxymercuribenzophenone-2′-sulphonic acid,



with foreign matter consisting of ammonium 2,4-dihydroxybenzophenone-2-sulphonate, sodium acetate and water.

A flesh colored or pink powder easily soluble in hot water up to 10 per cent. Solutions of 2.5 per cent or stronger gel or form a deposit on cooling. The color of the solution varies with concentration; a 0.5 per cent solution has a brownish-pink color with greenish fluorescence, the color becoming browner in more concentrated solutions. The solution produces no stain on skin or fabrics.

Uses—A local antiseptic and germicide recommended for superficial infections. It is used for wet dressings of wounds, and also for irrigation of wounds and of infected bladders.

Dose—For wet dressing of wounds and irrigation of infected wounds, a 0.1 per cent solution is used For prophylactic treatment of urinary infection, postoperative cystitis, acute gonorrhea, abscess and carbuncle, a 0.5 per cent solution is employed. Solutions of 2.5 per cent or greater strength gelatinize on standing.

Manufactured by Hynson, Westcott and Dunning.

Metaphen, N. N. R.—Bisacetoxymercuri-4-nitro-2-cresol. $(CH_3COOHg)_2$: $(C_6H.CH_3.OH.NO_2)$ — Metaphen contains from 58 to 60 per cent of mercury in organic combination.

A yellow, odorless and tasteless substance; insoluble in water, almost insoluble in methyl alcohol, acetone, ether and aqueous sodium carbonate and sodium bicarbonate solution; soluble in dilute aqueous sodium hydroxide solution and in ammonium hydroxide solution; soluble in boiling glacial acetic acid and in nitric acid at room temperature.

Uses—Metaphen is a germicide, more powerful than mercuric chloride and certain organic mercury compounds when tested on cultures of *Staphylococcus aureus* and *Bacillus typhosus*. It is stated to be relatively non-irritating when applied to mucous membranes or the skin and to be without deleterious action on metallic instruments or rubber. Metaphen is claimed to be relatively non-toxic.

Metaphen is proposed for use in the treatment of gonorrhea, infections of the eye, for skin sterilization, and for sterilization of instruments and rubber.

Dose—Solutions of metaphen in water are prepared with the aid of sodium hydroxide. For disinfection of instruments solutions of 1 :5000 to 1 : 1000; for application to the skin solutions of 1 : 5000 to 1 :1000; for ophthalmological use solutions of 1 : 10,000 to 1 : 5000 and for urethral irrigation solutions of 1 : 5000 to 1 : 10,000 are proposed.

Manufactured by The Abbott Laboratories.

Novasurol, N. N. R.—The double salt of sodium mercurichlorphenyl oxyacetate with diethylbarbituric acid (barbital)—$(NaOOCCH_2.O).Cl.C_6H_3.Hg[CO.NHCO.C(C_2H_5)_2.CONH]$—Novasurol contains 33.9 per cent of mercury.

A white, crystalline powder, odorless; soluble in cold water. The solution is slightly alkaline. Addition of strong acids to a solution of novasurol yields a precipitate consisting of diethyl barbituric acid, and the mercury derivative of chloro-phenyloxyacetic acid; on heating the solution the latter breaks up to mercuric chloride and chloro-phenyloxyacetic acid.

Uses—Novasurol was introduced originally as an antisyphilitic, but seems to be used chiefly as a diuretic. It has the advantage over mild mercurous chloride and other insoluble mercury compounds in that it is soluble and may be administered by intramuscular or intravenous injection.

As an antisyphilitic, novasurol has generally been injected intravenously mixed with one of the arsphenamines; this is considered by some to be the most satisfactory method of obtaining the combined action of arsenic and mercury. It is recommended, however, that this treatment be followed by the administration of mercury by one of the usual methods.

Dose—The dose as a diuretic ranges from 1 to 2 cc. of the 10 per cent solution injected intramuscularly or intravenously. It is recommended that 0.75 cc. be given first, in order to determine the patient's tolerance for mercury. If the drug is well borne, the dose can be increased to 1 cc. or up to 2 cc., according to the effect observed. The drug is given once or twice a week. Digitalis may be given as indicated.

The injections are said to be painless usually, or at least the pain and discomfort are slight and transient; induration at the site of injection is said to be of rare occurrence and of short duration.

The initial dose as an antisyphilitic is 0.75 cc. or 1 cc. of the 10 per cent solution injected intramuscularly once or twice weekly; later the dose may be increased to 2 cc. Recently it has been administered with arsphenamine; 1 cc. of the 10 per cent solution of the drug being mixed with a dose of the arsphenamine and injected intravenously: this is repeated about every five days until eight doses have been taken.

Manufactured by The Bayer Company, Inc.

Calomelol, N. N. R.—*Hydrargyri Chloridum Mite Colloidale*—Colloidal Calomel—A colloidal form of calomel, containing albuminoids.

A white-gray, odorless and tasteless powder, containing 80 per cent of mercurous chloride and 20 per cent of protein. With water, it forms an opalescent suspension insoluble in alcohol, ether and benzene. (In these suspensions, colloidal bodies are in such an extreme state of subdivision that they were formerly supposed to be in solution and are still so considered.) It is precipitated from its aqueous suspension by acids, the precipitate being redissolved by alkalies.

Uses—The action of calomelol is the same as that of calomel, but it is claimed that it is superior because of its power of forming colloidal suspension in water, acting more rapidly and efficiently, and that it is non-irritant. The indications for its use are the same as for calomel.

Dose—Internally, the same as calomel. Externally it is used as a dusting powder, mixed with an equal quantity of starch or of a mixture of starch and zinc oxide, or in the form of calomelol ointment. It should be protected from the light.

Manufactured by Heyden Chemical Company.

CHAPTER LXII

AMYLACEOUS AND MUCILAGINOUS PRINCIPLES AND THEIR PRODUCTS

STARCH has the same chemical composition as cellulose, $(C_6H_{10}O_5)n$, and is closely allied to it in some of its chemical properties. Starch is stored up in plant cells and is of future usefulness in the formation of their cell-walls, conversion into soluble carbohydrates, etc. It exists in the form of granules, the shape of which may be described as spherical, ellipsoidal, ovoid, lenticular polygonal, or irregular, and it is possible to identify the starches obtained from various plants, with the aid of the microscope, through the shape and size of the granules.

The granules consist of layers of different densities, arranged concentrically around a point termed the hilum, which is usually at one end of the granule. Corn starch is official in the U. S. P., and potato starch as a reagent in the assay of extract of malt.

AMYLUM. U.S. Starch

[**Amyl.**—CORN STARCH]

Starch consists of the granules separated from the grain of *Zea Mays* Linné (Fam. *Gramineæ*).

Starch contains but a trace of foreign organic matter and yields not more than 0.5 per cent of ash, and not more than 14 per cent of moisture.

Preparation—In making starch from corn, the germ must be separated mechanically and the cells then softened so as to permit the escape of the starch granules. This is generally done by permitting it to become sour and decomposed, stopping the fermentation before the starch is affected. Upon the small scale, starch may be made from wheat flour by making a stiff ball of dough and kneading it while a small stream of water trickles upon it. The starch is carried off with the water, while the *gluten* remains as a soft, elastic mass; the latter may be purified and used for various purposes to which gluten is applicable. The quality of commercial starch largely depends upon the purity of the water used in its manufacture. Starch may be made from potatoes by first grating them, and then washing the soft mass upon a sieve, which separates the cellular substances and permits the starch granules to be carried through. The starch must then be thoroughly washed by decantation, and the quality of this starch also depends largely upon the purity of the water that is used in washing it.

Description and Physical Properties—In irregular, angular white masses or in fine powder; consisting chiefly of polygonal, rounded or spheroidal starch grains from 0.003 to 0.035 mm. in diameter and usually with a lenticular or 3- to several-rayed central cleft; inodorous; taste characteristic, slight.

Starch is insoluble in cold water and in alcohol.

The individual grains of Starch are colored a deep blue by iodine T.S.

Tests for Identity—Boil 1 Gm. of Starch with 15 cc. of water: upon cooling, a translucent, whitish jelly forms.

Tests for Purity—Triturate about 0.5 Gm. of Starch with 5 cc. of distilled water: the mixture is neutral to litmus paper.

Add 10 cc. of distilled water to 1 Gm. of Starch, and acidify with 0.5 cc. of hydrochloric acid: the mixture should show no blue color within five minutes on the addition of three drops of potassium ferrocyanide T.S. (*iron*).

U. S. P. Preparation—Glyceritum Amyli. It is used as a diluent in powdered extracts.

N. F. Preparations—Pasta Resorcinolis Fortis; Pasta Resorcinolis Mitis; Pasta Zinci; Stilus Acidi Salicylici Dilubiles.

Starch is present in many drugs, and is an important constituent of many vegetable foods.

Starch, when moistened with diluted acids and heated, or through the action of diastase, or even when heated alone, is converted into *dextrin*, a substance resembling gum in appearance and properties. Dextrin is largely dissolved by water, hot or cold, and forms a viscous solution, from which it is precipitated by alcohol. Large quantities of dextrin are now made both in America and abroad, and used for various purposes in the arts, under the name of *artificial gum* or *British gum*. It is found in the market in the form of a white, brilliant powder, or in small masses or fragments resembling natural gum. It may be distinguished from gum arabic by the taste and the peculiar, harsh sensation when rubbed in the hand. It is official in the N. F. (see page 889).

Inulin, $(C_6H_{10}O_5)n$, is a substance closely allied to starch. It is found in some of the plants belonging to the family *Compositæ*, as Inula, Taraxacum, Pyrethrum, Lappa, etc. It has also been found, according to Kraus, in plants of the *Campanulaceæ*, *Goodeniaceæ*, *Lobeliaceæ*, and *Stylidaceæ*. It differs from starch in the following particulars: it is colored yellow by iodine, does not gelatinize with water, and is not found in plants in the form of granules having concentric layers like starch.

Uses—Starch is used in a number of official preparations chiefly because of its absorbent properties; also used as a filler or diluent in tablets and, in the latter, as a disintegrator (see page 1706). It is used externally as an absorbent, and is applied to the skin by dusting. It is also used to make pastes for applying in skin diseases.

Unofficial Amylaceous Substances and Derivatives

Acorn	From the genus *Quercus*. Acorns contain besides starch a peculiar saccharine substance, *quercite*
Bean	From *Faba vulgaris* and *Phaseolus vulgaris*
Barley	*Hordeum vulgare*. Contains 60 to 68 per cent of starch, glutin, gum, and sugar
Canna	From the rhizome of *Canna edulis*. Fam. Marantaceæ, Cannæ. Indigenous to Peru and Brazil. The starch granules are very large, and exhibit a glistening or satiny appearance. It forms a cloudy but very tenacious jelly with boiling water
Cassava, Tapioca, Manioc	From the root of *Manihot utilissima*. Fam. Euphorbiaceæ. Habitat, Tropical America. The starch granules are about half the size of the potato starch granules. *Pearl* or *flake tapioca* occurs in somewhat translucent pieces, inodorous, having an insipid taste
Curcuma, Turmeric	From the rhizome of *Curcuma longa*. Fam. Zingiberaceæ. Habitat, Southern Asia. The starch granules are rather larger than those of maranta
Maranta Arrowroot	From the rhizome of *Maranta arundinacea*. Fam. Marantaceæ. Indigenous to West Indies and tropical America. Prepared by removing the scales from the rhizome, mashing and grinding in a mill until reduced to a pulp, then suspending this in water and separating the fibrous portion, either by hand or sieve; lastly, washing thoroughly, and drying with a gentle heat. The yield is from 13 to 20 per cent of fecula. It forms an opaque jelly with concentrated hydrochloric acid
Oats	From *Avena sativa*. Fam. Gramineæ. Habitat, Asia, cult. The grain contains 64 to 66 per cent of starch, besides protein compounds, fat, salts, etc.
Pea	From *Pisum sativum*. It yields about 37 per cent of starch
Potato	(See U. S. P. Reagents, Chapter XCII).
Sweet Potato	From *Convolvulus Batatas*. The yield of starch is about 16 per cent
Rice	From *Oryza sativa*. Prepared by heating rice with weak soda-lye, which dissolves the nitrogenous impurities and leaves pure starch, then adding a solution of borax to facilitate the separation of the starch from the gluten. The yield is about 88 per cent
Rye	From *Secale cereale*. The yield of starch is about 64 per cent
Sago	From the pith of *Metroxylon Rumphii* and *M. læve*. Fam. Palmæ. Prepared by powdering the pith of the tree, washing with water to remove woody tissue and other impurities; lastly, drying carefully and granulating
Wheat	From *Triticum vulgare*. Fam. Gramineæ. Formerly official, now replaced by corn starch

MALTUM. U. S. Malt

Malt is the grain of one or more varieties of *Hordeum vulgare* Linné (Fam. *Gramineæ*), partially germinated artificially, and containing amylolytic enzymes.

Description and Physical Properties—Yellowish or amber-colored grains. Malt is crisp when broken, the interior surface being nearly white. It has an agreeable, characteristic odor and a sweet taste, due to the conversion of the starch of the seed into maltose through the action of the diastase. Malt floats on cold water.

For the subsequent tests prepare an infusion as follows: Mix 10 Gm. of Malt, in coarse powder, with 100 cc. of distilled water, and maintain the mixture at a temperature of from 50° to 55° C. for one hour, occasionally stirring. Place it upon a filter, and, when the liquid has passed through, wash the contents of the filter with distilled water, in small portions, until the combined infusion and washings measure 200 cc.

Tests for Purity—The weight of the solid soluble constituents of Malt, obtained by evaporating to dryness on a water bath an aliquot portion of the freshly prepared, aqueous infusion, and drying the residue for one hour at 100° C. is not less than 70 per cent of the Malt taken.

The acidity of Malt, determined by titrating an aliquot portion of the freshly prepared infusion with tenth-normal sodium hydroxide, using phenolphthalein T.S. as indicator, does not exceed 0.3 per cent calculated as lactic acid.

Preserve protected from heat and moisture.

U. S. P. Preparation—Extractum Malti.

Preparation—When barley is steeped for two or three days in water, it swells, becomes somewhat tender, and the water is colored reddish-brown. If the water is drained off, and the barley is spread about two feet thick upon a floor (a stone floor is generally used), it heats spontaneously, and germination begins, the radicle making its appearance first. The growth of the grain is partially stopped at this stage by spreading it more thinly, and turning it over for two days. It is then raked into heaps and allowed to stand a day, when it becomes hot, and is subsequently thoroughly dried in a kiln by a slow, regulated moderate heat. The resulting product is called *malt*, and it differs in quality according as it is more or less soaked, drained, germinated, dried, or baked. It is distinguished by its color, being pale, amber, brown, or black malt, according to the degrees of heat used in drying it. The object of converting grain into malt is to bring about the development of an enzyme called *diastase*. The effect of this enzyme during the process of *malting*, as the operation is called, is to change the *starch* naturally present in the grain into *maltose*, a peculiar kind of sugar, and dextrin. The diastase which is developed is capable of converting into maltose much more starch than is contained in the grain in which it is produced; hence, if good malt is added to a certain quantity of unmalted grain, the starch in the latter may be also converted into maltose. Malt seldom contains diastase in larger proportion than two parts in a thousand. Diastase is separated from malt by bruising the malt, adding about half its weight of water, expressing strongly, treating the viscid liquid thus obtained with sufficient alcohol to destroy its viscidity, then separating the coagulated albuminous and gummy matter, and adding a large excess of alcohol, which precipitates the diastase in an impure state. To render it pure, it must be redissolved in water, and reprecipitated by alcohol. Although malt has been manufactured in large quantities for centuries for brewing purposes and for converting starches into sugars for the purpose of manufacturing alcohol therefrom by fermentation, it is now also employed in medicine, in the form of extracts of malt, malt foods, etc. Its usefulness in this connection is due to the fact that the amount of diastase present in good malt has the power of *rendering soluble starchy substances which are taken into the stomach as food* and a good extract of malt is not only an easily digested food product, but also actively aids in the digestion of starchy foods. Some of the commercial malt extracts are practically valueless, as they consist of glucose colored with caramel and slightly flavored with extract of malt.

Malt is used as a nutrient, digestant flavoring, and emulsifying agent.

Unofficial Preparation

DIASTASUM. U. S. P. IX. Diastase

Although no longer official diastase is sometimes used or prescribed. The formerly official description and tests were as follows:

A mixture containing amylolytic enzymes obtained from an infusion of malt. It converts not less than 50 times its weight of potato starch into sugars.

Preparation—It is prepared by adding alcohol to an infusion of malt at a temperature not exceeding 60° C., collecting and purifying the precipitate.

Another form of diastase known by the proprietary name of *taka diastase* is the product of the growth of a fungus, *aspergillus oryzæ*, upon steamed rice. It is not identical with malt diastase either in composition or digestive properties. Malt diastase acts upon gelatinized starch at a temperature of 45° to 55° C. with the result that the starch is transformed first into *amylodextrin*, *erythrodextrin*, *achroödextrin* and finally into maltose.

Description—It occurs as a yellowish-white amorphous powder or in translucent scales. It converts starch into dextrin and maltose.

Odor and Taste—Odorless and tasteless.

Diastase gradually loses its amylolytic power on keeping; this power is destroyed by heating its solutions above 85° C. (185° F.) or by the addition of much acid and is diminished by the presence of acids or alkalies.

Solubility—Diastase is soluble in water, the solutions being more or less turbid; almost insoluble in alcohol.

Assay—Mix a quantity of potato starch, purified as directed under *Pancreatinum*, equivalent to 5 Gm. of dry starch, in a beaker with 10 cc. of cold distilled water. Add 140 cc. of boiling distilled water, and heat the mixture on a water bath with constant stirring for two minutes, or until a translucent, uniform paste is obtained. Cool the paste to 40° C. in a water bath previously adjusted to this temperature. Prepare a fresh solution of 0.1 Gm. of Diastase in 10 cc. of distilled water at 40° C. and add it to the paste. Mix them well and maintain the same temperature for exactly thirty minutes, stirring frequently; a thin, nearly clear liquid is produced. Add at once 0.1 cc. of this liquid to a previously made mixture of 0.2 cc. of tenth-normal iodine V.S. and 60 cc. of distilled water; no blue or reddish color is produced.

Preserve it in well-closed containers, protected from light, heat and moisture.

Uses—It is used as a digestant for starchy foods in doses of one to eight grains (0.06-0.5 Gm.). As it is not active in acid media, it should be given about a half hour after beginning a meal while the stomach is yet alkaline.

Gums and Mucilaginous Substances

The natural gums and mucilaginous principles of plants were formerly thought to be carbohydrates. They are probably of a glucosidal nature as upon hydrolysis they yield sugars and characteristic acids of high molecular weight.

Gums are amorphous and transparent or translucent. They are all insoluble in alcohol. Some dissolve completely in water, giving viscid solutions, others merely swell in water to form a paste or jelly, a few are almost insoluble. Soluble gums yield levorotatory solutions which are precipitated by basic lead acetate solution or normal lead acetate solution.

Upon hydrolysis gums yield *galactose* and *pentoses* as *arabinose* or *xylose*.

Upon oxidation with nitric acid gums yield *mucic*, ($C_6H_{10}O_8$), *saccharic*, ($C_6H_{10}O_8$), and *oxalic*, ($C_2H_2O_4$), *acids*. The true gums are usually found in combination with potassium, calcium, or magnesium.

In the classification of gums the following distinctive types are recognized: *arabin*, which is completely soluble in water; *bassorin* and *cerasin*, which are partially soluble or swell in contact with water; *mucilages* and *pectins*, which merely swell to form jellies. Many gums are complex mixtures of several of these types. When the unqualified word *gum* is used in the enumeration of plant constituents it has no definite meaning.

ACACIA. U. S. Acacia

[Acac.—Gum Arabic]

Acacia is the dried gummy exudation from the stems and branches of *Acacia Senegal* Willdenow, or of some other species of *Acacia* (Fam. *Leguminosæ*).

Acacia yields not more than 1 per cent of water-insoluble residue, and not more than 15 per cent of moisture.

Description and Physical Properties—In roundish tears of various sizes, or broken into angular fragments, with a glass-like, sometimes iridescent fracture, opaque from numerous fissures, but transparent and nearly colorless in thin pieces; nearly inodorous; taste insipid, mucilaginous; insoluble in alcohol, but soluble in about twice its weight in cold water, forming a thick, mucilaginous liquid. The *powder* should be white and free from foreign particles.

For further description and tests see the U. S. P. X.

U. S. P. Preparations—Mucilago Acaciæ; Emulsum Olei Morrhuæ; Emulsum Olei Terebinthinæ; Pilulæ Phosphori; Pulvis Cretæ Compositus.

N. F. Preparations—Emulsum Olei Morrhuæ cum Hypophosphitibus; Emulsum Olei Ricini; Emulsum Petrolati; Mistura Copaibæ; Mistura Copaibæ et Opii; Pilulæ Ferri Iodidi; Trochisci Eucalypti Gummi.

This valuable gum consists mainly of arabic acid, or arabin, combined with lime, potassium, or magnesium, and hence it may be called calcium, potassium, or magnesium arabate. It is bleached by exposure to the sun.

One hundred parts of diluted alcohol containing 22 per cent of alcohol by volume dissolve fifty-seven parts of gum; diluted alcohol containing 40 per cent of alcohol takes up ten parts, while 50 per cent alcohol dissolves only four parts. A knowledge of these solubility figures will enable the pharmacist to determine the possibility of precipitation in extemporaneous mixtures when both acacic and alcoholic liquids are present.

Uses—In pharmacy, acacia is extensively used for the suspension of insoluble substances in water, and for the formation of pills and troches. Two kinds of powdered acacia are used, one a coarse powder called *granulated*, the other *finely dusted*. The granulated dissolves more readily in water, because it has lost during desiccation only a part of its moisture, while in preparing the "finely dusted" powder, the high heat necessarily used to dry it thoroughly drives off nearly all of the water. Its easy solubility and its absence of tendency to form "lumps" cause the coarse powder to be preferred for solutions, emulsions, etc. Acacia is used as a binding agent in emulsions, pills, troches, etc. (See official preparations and the Chapter on Colloids.)

It is used for its demulcent action in inflammations of the throat or stomach.

TRAGACANTHA. U. S. Tragacanth

[Trag.—Gum Tragacanth]

Tragacanth is the dried gummy exudation from *Astragalus gummifer* Labillardière, or other Asiatic species of *Astragalus* (Fam. *Leguminosæ*).

Description and Physical Properties—In narrow or broad bands, more or less curved or contorted, marked by parallel lines or ridges, white or faintly yellowish, translucent, horn-like, tough. Rendered more easily pulverizable by a heat of 50° C.; inodorous; taste insipid, mucilaginous. (For further description and tests see the U. S. P. X.)

Powdered Tragacanth—White, angular fragments of mucilage with circular or irregular lamellæ; starch grains from 0.003 to 0.025 mm. in diameter, spherical to elliptical, with occasional 2- to 4-compound grains, many of the grains being swollen and more or less altered. The powder shows few or no fragments of lignified vegetable tissue (*Indian gum*).

U. S. P. Preparations—Mucilago Tragacanthæ; Pilulæ Ferri Carbonatis; Trochisci Acidi Tannici; Trochisci Ammonii Chloridi.

N. F. Preparations—Emulsum Olei Morrhuæ cum Malto; Glyceritum Tragacanthæ; Stili Acidi Salicylici Dilubiles; Syrupus Trifolii Compositus; Trochisci Eucalypti Gummi; Trochisci Ulmi.

This gum consists of bassorin, and a soluble gum (not arabin). Introduced into water, it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this paste forms a uniform mixture; but in the course of one or two days the greater part separates, and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. A common adulteration is *Indian Gum*, and the Pharmacopœia has introduced several tests to detect its presence.

Uses—Tragacanth, in the form of a glycerite, affords an excellent pill excipient; the powder itself is often used to stiffen a pill mass and render it adhesive. It is also largely employed as an emulsifying agent and a small amount of potassium bitartrate added to the powdered tragacanth, greatly increases its emulsifying properties. It is sometimes used as a demulcent in sore throat.

AGAR. U.S. Agar

[**Agar-agar**—Chinese or Japanese Gelatin (Isinglass)]

Agar is the dried mucilaginous substance extracted from *Gelidium corneum* (Hudson) Lamouroux and other species of *Gelidium* and closely related algæ (Class *Rhodophyceæ*).

Agar contains not more than 1 per cent of foreign organic matter, and yields not more than 1 per cent of acid-insoluble ash, and not more than 16 per cent of moisture.

Description and Physical Properties—Usually in bundles from 3 to 6 dm. in length, consisting of thin, translucent, membranous, agglutinated pieces 4 to 10 mm. in width; externally yellowish-white or brownish-white, tough when damp, brittle when dry, with a slight odor and a mucilaginous taste. It is also obtainable commercially in the form of powder and also in threads.

For additional description and tests, see the U. S. P. X.

Uses—It is used in culture media for bacteriological work (see Diagnostical Reagents, Chapter XCIII); also administered internally, in doses of two to three drachms (8 to 12 Gm.), to give moisture and bulk to the intestinal contents in chronic constipation.

It is also popularly employed as an emulsifying agent for liquid petrolatum, frequently accompanied with phenolphthalein in the form of *petrolatum-agar emulsions.*

Unofficial Agar Preparation

Phenolphthalein-Agar—Agar impregnated with phenolphthalein, 100 Gm. containing 3 Gm. of phenolphthalein.

Actions and Uses—Phenolphthalein-agar is claimed to have the properties of agar augmented by the action of phenolphthalein.

Dose—Fifteen grains (1 Gm.), twice daily, after breakfast and supper, increased or diminished according to requirements.

Manufactured by the Reinschild Chemical Company.

ULMUS. U.S. Elm

[Elm Bark, Slippery Elm, Slippery Elm Bark, Red Elm, Indian Elm, Sweet Elm, American Elm]

Elm is the dried inner bark of *Ulmus fulva* Michaux (Fam. *Ulmaceæ*).

Description and Physical Properties—In flat pieces, varying in length and width, about 3 mm. thick, tough, pale brownish-white, the inner surface finely ridged; fracture fibrous and mealy; the transverse section delicately checkered; odor slight, peculiar; taste mucilaginous, insipid.

For further description and tests, see the U. S. P. X.

N. F. Preparation—Trochisci Ulmi.

This bark contains a mucilage which is capable of being precipitated from its aqueous solution by alcohol and lead acetate. It is much used as a demulcent.

ALTHÆA. U.S. Althea

[Marsh Mallow Root, Marshmallow]

Althea is the dried root of *Althæa officinalis* Linné (Fam. *Malvaceæ*), deprived of the brown, corky layer and small roots.

Description and Physical Properties—In cylindrical or somewhat conical pieces, from 10 to 15 cm. long, 10 to 15 mm. in diameter, deeply wrinkled; deprived of the brown, corky layer and small roots; externally white, marked with a number of circular spots, and of a somewhat hairy

appearance from the loosened bast-fibers; internally whitish and fleshy. It breaks with a short, granular, and mealy fracture, has a faint, aromatic odor, and a sweetish, mucilaginous taste.

For further description and tests, see the U. S. P. X.

U. S. P. Preparations—Massa Hydrargyri; Pilulæ Ferri Carbonatis.

N. F. Preparations—Species Pectorales; Syrupus Althææ.

This root, which is generally imported from Europe, contains a large quantity of mucilage associated with *asparagin*, sugar, and starch. It is used as a demulcent and as a filler for pill masses (see the official preparations above). The leaves are official in the N. F.

LINUM. U.S. Linseed

[Flaxseed]

Linseed is the dried ripe seed of *Linum usitatissimum* Linné (Fam. *Linaceæ*).

Linseed contains not more than 2 per cent of other seeds or foreign organic matter, and yields not less than 30 per cent of non-volatile, ether-soluble extractive, at least 98 per cent of which is saponifiable.

Description and Physical Properties—About 4 or 5 mm. long, oblong-ovate, flattened, obliquely pointed at one end, brown, glossy, covered with a transparent, mucilaginous epithelium, which swells considerably in water; the embryo whitish or pale greenish, with two large, oily, plano-convex cotyledons, and a thin perisperm; inodorous; taste mucilaginous, oily and bitter.

For further description and tests, see the U. S. P. X.

Linseed Meal—Yellow with numerous brown fragments; the fragments of both seed-coat and kernel mostly very coarse and with the same cellular tissues as those of the powder.

N. F. Preparation—Species Emollientes.

Linseed contains 15 per cent of mucilage in the epithelium, and from 20 to 35 per cent of fixed oil in the nucleus, besides resin, sugar, wax, etc. The mucilage is soluble in water, but more readily in hot water, forming a thick, viscid liquid. Alcohol and lead subacetate precipitate it from its aqueous solution. The mucilage is an important constituent; the seed is used in its unground state for making a demulcent infusion. Ground flaxseed is very useful to the pharmacist for making lutes, and medicinally, it is valuable for making poultices. Whole linseed is occasionally used for its laxative effect. The fixed oil is very valuable in the arts because of its drying properties. (See Oleum Lini.)

ALTHÆA FOLIA. N.F. Althea Leaves

[Alth. Fol.—Marsh Mallow Leaves]

Althea Leaves consist of the dried leaves of *Althæa officinalis* Linné (Fam. *Malvaceæ*).

Althea Leaves contain not more than 5 per cent of stems and fruits or other foreign organic matter.

Description—Crumpled or matted; gray-green or yellowish gray-green; densely and finely tomentose throughout; petioles 1 to 6 cm. long; blades 3 to 15 cm. long and 3 to 10 cm. wide, thin, cordate or rhomboidal-ovate in outline, rounded, or nearly truncate at the base, acute at the apex; margin doubly serrate-dentate, the principal teeth from 1 to 3 pairs, the lowest almost large enough to be regarded as lobes, the secondary very irregular, triangulate, acute, broader than long, the sinuses acute; 2 to 6 principal veins originating with the midrib in the petiole, prominent underneath, terete; branches of midrib arising at a wide angle; nearly straight, each terminating in a marginal tooth. Odor slight, scarcely characteristic; taste mucilaginous.

For further description see the N. F. V.

N. F. Preparation—Species Emollientes.

Uses—Used as a demulcent, emollient and protective in doses of about thirty grains (2 Gm.).

AVENA SATIVA. N.F. Oat

[Aven. Sat.]

Oat is the grain of *Avena sativa* Linné (Fam. *Gramineæ*).

Oat contains not more than 5 per cent of other seeds or of foreign organic matter.

Descriptions and Tests—See N. F. V.

Uses—In the form of meal, known as *oatmeal*, it affords a nutritious, bland food, which from its somewhat laxative tendency, is often preferable to other amylaceous preparations.

To prepare *oatmeal gruel*, boil an ounce of the meal with three pints of water and strain. Sugar and lemon may be added.

Preparations—Elixir Hydrastis Compositum, Fluidextractum Avenæ Sativæ.

Dose—60 grains (4 Gm.).

CHONDRUS. N. F. Chondrus
(U. S. P. IX)

[Chondr.—Irish Moss, Carrageen]

Chondrus is the dried bleached plant of *Chondrus crispus* (Linné) Stackhouse or of *Gigartina mamillosa* (Goodenough et Woodward) J. Agardh (Fam. *Gigartinaceæ*).

Chondrus contains not more than 2 per cent of foreign organic matter.

Description—Entire plants matted together, consisting of a slender stalk from which arises a series of dichotomously branching, more or less flattened segments, emarginate or deeply cleft at the tips; from 5 to 15 cm. in length and 1 to 10 mm. in width; yellowish-white; translucent, frequently coated with a calcareous deposit which effervesces with hydrochloric acid; sometimes with fruit bodies or sporangia embedded near the apex of the segments (in *C. crispus*) or with sporangia borne on short tuberculated projections or stalks, more or less scattered over the upper portion of the segments (in *G. mamillosa*); somewhat cartilaginous. Odor slight, seaweed-like; taste mucilaginous, saline.

For further description see the N. F. V.

N. F. Preparation—Mucilago Chondri.

This alga grows in the Atlantic Ocean. It contains 70 per cent of a mucilaginous principle, which has been termed *carrageenin*. This differs from ordinary *gums* by not precipitating with alcohol, from *starch* by not becoming blue upon the addition of iodine, and from *pectin* by not being precipitated by lead subacetate.

Uses—Chondrus is used principally as an emulsifying agent for liquid petrolatum (see page 889) and for cod liver oil, the mucilage being used, and to form a "sick diet" jelly, one part being sufficient to form a jelly with sixty parts of water. It should be previously soaked in a small quantity of water, to dissolve adherent salts, and this water thrown away.

Chondrus Gelatin of the N. F. IV was prepared by washing 100 Gm. of chondrus, with cold water, then placing it in a suitable vessel, adding 5000 cc. of hot water, and heating on a water bath for fifteen minutes, frequently stirring. The decoction must then be strained while hot, through a strong muslin strainer, the strained, mucilaginous liquid returned to the water bath, evaporated to a semi-fluid consistence, then transferred to shallow, flat-bottomedt rays, and evaporated at a temperature not exceeding 90° C. so that the product may be detached in scales. It is used as a demulcent and nutritive.

DEXTRINUM ALBUM. N. F. White Dextrin
[Dext. Alb.]

A mixture of soluble carbohydrates, amylodextrin, achroödextrin, erythrodextrin and maltodextrin, together with a variable amount of unconverted starch, obtained by the incomplete hydrolysis of starch by the action of an acid.

Description and Physical Properties—White Dextrin occurs as a white, glistening, non-hygroscopic, amorphous powder, producing a peculiar and characteristically harsh sensation when rubbed in the hand; odorless and having a sweetish taste.

Only partly soluble in cold water, but completely soluble in three parts of water on boiling.

Tests for Identity—An aqueous solution prepared in the cold and filtered is colored wine-red by iodine T.S.; an aqueous solution prepared with boiling water is colored blue by iodine T.S.

Alkaline cupric tartrate solution is not changed by a solution of White Dextrin in the cold, but is reduced on boiling.

Tests for Purity—Separate portions of a freshly prepared, filtered solution in cold water do not become turbid on the addition of calcium chloride T.S., or of calcium hydroxide T.S. (*oxalic acid*).

Not more than 5 per cent of White Dextrin is soluble in boiling alcohol (*dextrose*). Dry White Dextrin at 110° C.: it loses not more than 10 per cent in weight (*moisture*).

Separate portions of a filtered aqueous solution of White Dextrin (1 in 20) are not immediately precipitated by lead acetate T.S., or by basic lead acetate T.S., but upon the addition of a few drops of ammonia water to the mixtures, precipitation occurs (difference from *natural gums*).

A solution of White Dextrin does not darken on the addition of hydrogen sulphide T.S. even when supersaturated with ammonia water (*metals*).

White Dextrin yields not more than 0.5 per cent of ash.

N. F. Preparations—Pasta Dextrinata; Stili Acidi Salicylici.

Uses—Used as the basis for dermatological pastes and commercially, on a large scale, for the making of *library paste* also for making the adhesive coating for gummed labels, envelope flaps, postage stamps, etc.

This product is known as *artificial gum* or *British gum*.

FUCUS. N. F. Fucus
[Bladderwrack]

Fucus is the dried thallus of *Fucus vesiculosus* Linné, *Fucus serratus* Linné, *Fucus Nodosus* Linné, or *Fucus siliqnosus* Linné Fam. *Fucaceæ*).

Fucus contains not more than 3 per cent of foreign organic matter and yields not more than 4 per cent of acid-insoluble ash.

Description—Sometimes a meter in length, but usually in shorter pieces, from 0.5 to 4 cm. in width, dichotomously branched, brownish-black, or slightly reddish, usually with a slight, whitish incrustation; flat, smooth, entire-margined, having a stout midrib throughout, along which are irregularly disposed pairs of air-vesicles which vary in diameter from 5 to 15 mm.; apex of thallus occasionally swollen, ovate or elliptical, about 5 mm. in diameter and bearing numerous receptacles. Odor strongly seaweed-like; taste saline and nauseous.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Fuci.

Uses—It is popularly employed as an "antifat" remedy but is probably of little value. Dose, ten grains (0.6 Gm.).

GALEGA. N. F. Galega
[Galeg.—European Goat's Rue]

Galega is the dried flowering herb of *Galega officinalis* Linné (Fam. *Leguminosæ*).

Galega contains no stems over 4 mm. in diameter and not more than 3 per cent of foreign organic matter.

Description—Stem smooth, erect, branched, when entire from 15 to 45 cm. long, commonly cut and broken; leaves oddly-pinnate with from 6 to 8 pairs of leaflets; stipules lanceolate, sagittate on one side; leaflets bright green, smooth or slightly hairy, short petioled, lanceolate or ovate-lanceolate, obtuse, slightly mucronate, from 2 to 5 cm. long and from 2 to 6 mm. in width; flowers small, white to violet, in axillary racemes. Odor indistinct; taste mucilaginous, slightly bitter and astringent; it colors the saliva yellowish-green.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Galegæ.

Uses—It is used as a diaphoretic and galactagogue in doses of sixty grains (4 Gm.).

MALVÆ FOLIA. N. F. Mallow Leaves
[Malv. Fol.]

Mallow Leaves consist of the dried leaves of *Malva sylvestris* Linné and of *Malva rotundifolia* Linné (Fam. *Malvaceæ*).

Mallow Leaves contain not more than 10 per cent of other parts of plants yielding the drug and not more than 5 per cent of foreign organic matter.

Description and Physical Properties.

Unground Mallow Leaves—Leaves of *Malva sylvestris*, petiolate with petioles up to 10 cm. in length, orbicular or reniform, slightly truncate or cordate at the base, from 10 to 11 cm. in length, and from 15 to 20 cm. in width, with 3 to 7 shallow, angular or rounded lobes, venation palmate, margins crenate-dentate, pubescent, on both sides. Leaves of *Malva rotundifolia*, with petioles up to 20 cm. in length, orbicular, up to 8 cm. in width, base deeply cordate, 5 to 7 shallow rounded lobes, venation palmate, margins with rounded blunt teeth, pubescence more scant than in *M. sylvestris*. Intermixed with the leaves are frequently found dark purple flowers and glabrous reticulated carpels (*M. sylvestris*) or pale bluish flowers and pubescent rounded carpels (*M. rotundifolia*). Inodorous; on chewing it becomes very mucilaginous, taste bland.

N. F. Preparation—Species Emollientes.

Uses—It is used as an emollient and demulcent.

SASSAFRAS MEDULLA. N. F. Sassafras Pith
[Sassaf. Med.]

Sassafras Pith is the dried pith of *Sassafras variifolium* (Salisbury), O. Kuntz (Fam. *Lauraceæ*).

Sassafras Pith contains not more than 1 per cent of foreign organic matter and yields not more than 0.5 per cent of acid-insoluble ash.

Description and Physical Properties—In sub-cylindrical, often curved or coiled pieces, from 2 to 10 cm. in length and from 2 to 5 mm. in diameter; very light in weight, externally whitish, occasionally with small fragments of adhering wood; fracture short. Odor slight, sassafras-like; taste mucilaginous.

Tests for Purity and Identity—Macerate 0.5 Gm. of Sassafras Pith with 25 cc. of cold distilled water for several hours and filter it through purified cotton: a mucilaginous solution is obtained which does not give a precipitate upon the addition of an equal volume of alcohol; if an excess of alcohol is added precipitation takes place.

For further description see the N. F. V.

N. F. Preparation—Mucilago Sassafras Medullæ.

Uses—The pith contains a delicate mucilage which is not precipitated from its aqueous solution by alcohol. The mucilage is principally employed as an eye wash.

VERBASCI FLORES. N.F. Mullein Flowers

[Verbasc. Flor.]

Mullein Flowers consist of the dried corollas, with adhering stamens, of *Verbascum phlomoides* Linné, or of *Verbascum thapsiforme* Schraeder (Fam. *Scrophulariaceæ*).

Mullein Flowers contain not more than 2 per cent of foreign organic matter. Flowers which have become brown should not be used.

Description and Physical Properties—Corolla light yellow, the outer surface grayish with a fine, soft, wooly indumentum, the inner surface sparsely hairy and finely veined; tube of the corolla 1 or 2 mm. in length and almost equally broad, the limb from 14 to 30 mm. in width, between wheel-shaped and saucer-shaped, obscurely two-lipped, the unequal lobes rounded, obovate. Stamens five, borne on the base of the corolla, shorter than the corolla, two of them longer than the other three, the filaments thick and fleshy, more or less pilose, especially the three shorter ones, usually orange-colored. Stamen-hairs, cylindrical, uni-cellular, non-branching, surface minutely reticulate, apex rounded, frequently enlarged. Pollen grains smooth, triangular and more or less rounded, from 0.025 to 0.035 mm. in diameter. Odor peculiar, agreeable; taste mucilaginous, not agreeable.

Tests for Purity and Identity—The flowers impart a yellow color to boiling water, and a rather permanent green color with dilute sulphuric acid, the latter color becoming brown upon the addition of alkalies.

N. F. Preparation—Species pectorales.

Uses—As a demulcent and expectorant. Dose, two drachms (8 Gm.).

VERBASCI FOLIA. N.F. Mullein Leaves

[Verbasc. Fol.]

Mullein Leaves are the dried leaves of *Verbascum Thapsus* Linné (Fam. *Scrophulariaceæ*).

Mullein Leaves contain not more than 2 per cent of foreign organic matter and yields not more than 4 per cent of acid-insoluble ash.

Description and Physical Properties.

Unground Mullein Leaves—Obovate with narrowed base, or varying to oblong or oblong-lanceolate, without a true petiole, obtuse or tending toward acuteness at the summit, from 1 to 6 dm. in length and from 3 to 15 cm. in width; very thick, rather tough when damp, brittle when dry, light yellowish-gray or greenish-gray, densely long-tomentose, with numerous, multicellular, branching, non-glandular hairs. Nearly odorless; taste mucilaginous and slightly bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Verbasci Foliorum.

Uses—As a demulcent and expectorant. Dose, one drachm (4 Gm.).

Unofficial Mucilaginous Substances

Bael-fruit	The dried, half ripe fruit of *Ægle Marmelos*. Fam. Aurantiaceæ. Habitat, Himalaya Mountains. Used principally in dysentery. Dose of fluidextract, 1 to 2 fluidrachms
Baobab	From *Adansonia digitata*. Fam. Sterculiaceæ. Habitat, Tropical Africa. Used as a tonic
Benne Leaves	From *Sesamum Indicum*. Fam. Pedaliaceæ. Habitat, India. Used as a stimulant
Blue-weed	From *Echium vulgare*. Habitat, Europe. Used chiefly as an emollient and protective
Borage	From *Borago officinalis*. Fam. Boraginaceæ. Habitat, Southern Europe. Used chiefly as an emollient and protective
Cashew-nut	From *Anacardium occidentale*. Fam. Terebinthaceæ. Habitat, Tropical America. Used externally and as a vermifuge
Comfrey-root	The root of *Symphytum officinale*. Fam. Boraginaceæ. Habitat, Europe. Used as a demulcent and astringent
Cydonium, Quince Seed	The seed of *Cydonia vulgaris*. Fam. Rosaceæ. Used for *Mucilago Cydonii*, 2 per cent quince seed, 98 per cent water
Evening Primrose	From *Ænothera biennis*. Fam. Onagraceæ. Habitat, North America

Unofficial Mucilaginous Substances—*Continued*

Fenugreek	The seeds of *Trigonella Fœnum-græcum*. Fam. Leguminosæ. Habitat, Western Asia. Used as an emollient, and in condition powders
Hog Gum	From *Rhus metopium*. Habitat, South America. Used as a demulcent
Hound's Tongue	From *Cynoglossum officinale*. Habitat, Europe and United States. Used as an emollient and protective
Jujube Berries	The fruit of *Zizyphus vulgaris*. Fam. Rhamnaceæ. Habitat, Asia Minor. Used as a laxative
Laminaria	From *Laminaria Cloustonia*. Fam. Algæ. Habitat, North Atlantic Ocean
Lungwort	From *Pulmonaria officinalis*. Habitat, Europe
Maidenhair	The fronds of *Adiantum Capillus-Veneris*. Fam. Filices. Used as a demulcent and stimulant
Mezquite Gum	From *Algarobia glandulosa*. Habitat, Texas
Okra	From *Hibiscus esculentus*. Habitat, Africa
Psyllium Fleawort Flea seed	The seed of *Plantago Psyllium*. A small, reddish-brown, shining, inodorous, and nearly tasteless seed. It becomes mucilaginous when chewed: It is recommended for administration in chronic constipation, as it absorbs moisture, becomes mucilaginous, gives bulk to the intestinal content, and aids in maintaining the regularity of the bowel movements. It is usually taken with a cereal, several tablespoonfuls or more being added.
Salep	From the tubers of *Orchis mascula*. Is very mucilaginous, only four grains being sufficient to make one fluidounce of water gelatinous
Virginia Lungwort	From *Pulmonaria Virginica*. Habitat, United States
Willow Herb	From *Epilobium angustifolium*. Fam. Onagraceæ. Used as a tonic and demulcent

CHAPTER LXIII

SUGARS AND SACCHARINE SUBSTANCES

The general classification of carbohydrates includes sugars, starches, gums and celluloses, all of which are of great importance in the life of the plant. Sugars are distinguished by sweetness of taste and solubility in water. The classification of sugars is based upon their chemical constitution and behavior toward hydrolytic agents such as mineral acids or enzymes.

There are a number of naturally occurring sugars containing five and six carbon atoms that cannot be split up any further by hydrolysis—these are called *monosaccharides* (or *monoses*), example, *dextrose* ($C_6H_{12}O_6$). Other sugars are known to split up under the influence of hydrolysis into two molecules of monosaccharides. Such sugars are known as *disaccharides*, example sucrose ($C_{12}H_{22}O_{11}$), which splits up according to the following equation:

$$\underset{\text{sucrose}}{C_{12}H_{22}O_{11}} + \underset{\text{water}}{H_2O} = \underset{\text{dextrose}}{C_6H_{12}O_6} + \underset{\text{levulose}}{C_6H_{12}O_6}$$

Still other sugars upon hydrolysis yield three, four, or more *monosaccharides*. These are termed respectively *trisaccharides*, *tetrasaccharides*, etc.

Starch and cellulose bear a close chemical relationship to the sugars and by hydrolytic change can be converted into sugars. They are therefore termed *polysaccharides*.

The following synopsis gives an idea of the foregoing relationships:

I. Sugars
- Monosaccharides
  - Trioses ($C_3H_6O_3$), glycerose
  - Tetroses ($C_4H_8O_4$), erythrose
  - Pentoses ($C_5H_{10}O_5$), arabinose, xylose, rhamnose; ($C_6H_{12}O_5$), fucose, quinovose
  - Hexoses ($C_6H_{12}O_6$), dextrose, levulose, sorbose, galactose, mannose
- Disaccharides
  - $C_{12}H_{22}O_{11}$, sucrose, mactose, maltose, isomaltose, trehalose, cellobiose, gentiobiose, melibiose
  - $C_{11}H_{20}O_{10}$, glucoxylose, primeverose, vicianose
- Trisaccharides ($C_{18}H_{32}O_{16}$), raffinose, gentianose, melezitose
- Tetrasaccharides ($C_{24}H_{42}O_{21}$), stachyose
- Artificial sugars belonging to the former groups and also to higher groups have been synthesized.

II. Non-sugars or Polysaccharides
- ($C_6H_{10}O_5$)n, starches, dextrin, inulin, glycogen, galactosane, mannosane
- Gums (a) natural gums and pentosanes
  (b) mucilages and pectic compounds
- Celluloses ($C_6H_{10}O_5$)n.

It will be seen that isomerism is a common phenomenon in the carbohydrates and especially in the sugars. Sugars are characterized by their optical activity, and the polariscope is an instrument used in their quantitative determination. Sugars are sometimes classified as *reducing sugars* or *non-reducing sugars*. The reagent used is Fehling's Solution or one of the similar alkaline copper solutions. The reduction is evidenced by a visible change in which the blue cupric solution loses its color, and cuprous oxide is formed as a red precipitate. This is used as a quantitative as well as a qualitative test (see Chapter on Urinalysis, page 1440).

Phenylhydrazine (see Reagents, page 1538) is used as a reagent for identifying and differentiating sugars, a series of compounds known as *ozazones* being produced.

GLUCOSUM. U.S. Glucose

[**Glucos.**—Syrupy Glucose, Liquid Glucose, Corn Syrup, Grape Sugar (when solid)]

A product obtained by the incomplete hydrolysis of starch. It consists chiefly of dextrose (d-glucose) [$C_6H_{12}O_6$ = 180.13], maltose, dextrins, and water.

Preparation—Glucose is obtained commercially by the action of very weak sulphuric acid or hydrochloric acid on starch.

The process for the manufacture of glucose is as follows: The starch, usually from corn, is mixed with five times its weight of water containing less than one per cent of hydrochloric acid, the mixture is heated to about 45° C., and then transferred to a suitable lead-lined vessel into which steam is passed under pressure until the temperature reaches 120° C. The temperature is maintained at this point for about an hour, or until tests show the complete disappearance of starch. The mass is then heated to volatilize most of the hydrochloric acid, sodium carbonate or calcium carbonate is added to neutralize the remaining traces of acid, the liquid is filtered, then decolorized in charcoal or bone-black filters, as is done in sugar refining, and finally concentrated in vacuum to the desired consistence.

If the crystallizable "*grape sugar*" (called *bread sugar* or *cerelose*) is desired, the conversion temperature is higher and the time of conversion longer. The term glucose as customarily used in chemical or pharmaceutical literature usually refers to dextrose ($C_6H_{12}O_6$), the crystallizable product. Syrupy glucose contains about thirty to forty per cent of dextrose mixed with about an equal proportion of dextrin, together with small amounts of other carbohydrates. Dextrose can be obtained as a hydroxide in small and laminated crystals from aqueous solution, and in anhydrous form in hard crystalline masses either from alcoholic solution or from very concentrated aqueous solution. It is less sweet than cane sugar. It is also less soluble in water, and much more soluble in alcohol. It has the specific gravity 1.54 to 1.57 when anhydrous. Strong mineral acids hardly act on dextrose, but destroy cane sugar with facility. On the other hand, grape sugar is destroyed by alkalies, with which cane sugar forms definite compounds. Dissolved in water and subjected to prolonged ebullition, dextrose undergoes very little alteration. Its solution rotates the plane of polarization of polarized light to the right, and is capable of undergoing the vinous fermentation directly, without passing through any intermediate state. It is characterized, also, in boiling solution, by reducing alkaline cupric tartrate (see Alkaline Cupric Tartrate Volumetric Solution), producing a reddish precipitate.

The name grape sugar is sometimes applied to the solid commercial form of dextrose because the principal sugar of the grape is dextrose, although the fruit has never been used as a source of the commercial supply. The term *starch sugar* and *corn sugar* have also been applied to it, and the corresponding terms *starch syrup* and *corn syrup* to the syrupy form, commonly called glucose. The official description of syrupy glucose is as follows:

Description and Physical Properties—A colorless or yellowish, thick, syrupy liquid. It is odorless, or nearly so, and has a sweet taste.

Glucose is very soluble in water, but is sparingly soluble in alcohol.

Tests for Identity—Add a few drops of an aqueous solution of Glucose (1 in 20) to 5 cc. of hot alkaline cupric tartrate T.S.: a copious red precipitate of cuprous oxide is produced (*distinction from sucrose*).

Tests for Purity—Introduce about 0.5 Gm. of Glucose into a wide-mouthed, tared weighing-bottle, weigh accurately, add 2 cc. of distilled water, evaporate at about 70° C., and dry the residue to constant weight at 90° C.: the loss in weight of the Glucose does not exceed 21 per cent (*water*).

Ash: not more than 0.5 per cent.

A solution of 5 Gm. of Glucose in 15 cc. of distilled water, mixed with 5 drops of phenolphthalein T.S., requires not more than 0.6 cc. of tenth-normal sodium hydroxide to produce a pink color (*free acid*).

Dissolve about 2 Gm. of Glucose in 50 cc. of distilled water, boil the solution for one minute, and cool: the addition of one drop of tenth-normal iodine to this solution produces no blue color (*starch*). On now adding a few drops of starch T.S. to the solution, a blue color is produced (*limit of sulphur dioxide*).

An aqueous solution of Glucose meets the requirements of the test for *heavy metals*, page 1519. If the solution of Glucose is not colorless, comparison must be made with 10 cc. of the same solution, to which a volume of distilled water, equal to that of the hydrogen sulphide T.S., has been added.

Dissolve 1.5 Gm. of Glucose in 5 cc. of distilled water, add 5 cc. of diluted sulphuric acid and 1 cc. of bromine T.S. and heat for five minutes on a water bath. Then add 0.5 Gm. of potassium iodide and five drops of stannous chloride T.S., cool, and test the solution for *arsenic*, page 1512. The stain, if any, is not greater than that produced in a test made with the same quantities of the reagents and 2 cc. of the standard arsenic test solution.

U. S. P. Preparations—Extractum Belladonnæ (Pilular); Extractum Hyoscyami; Extractum Stramonii (Pilular).

N. F. Preparation—Extractum Conii.

Uses—It is used officially as a diluent in pilular extracts (see official preparations above) and commercially it has replaced glycerin in many pharmaceutical preparations. It is sometimes given per rectum as a food in cases where feeding by stomach is impossible. It should not be used in the place of dextrose for intravenous injection (see below).

DEXTROSUM. U.S. Dextrose

[**Dextros.**—D-Glucose]

A sugar [$C_6H_{12}O_6.H_2O$ = 180.13] usually obtained by the hydrolysis of starch. The method employed for the preparation of dextrose is described under glucose (page 894).

Description and Physical Properties—A white, crystalline powder, or white granules. It is odorless, and has a sweet taste.

One Gm. of Dextrose is soluble in 1 cc. of water, and in 59 cc. of alcohol, at 25° C. It is more soluble in boiling water and in boiling alcohol.

Tests for Identity—An aqueous solution of Dextrose (1 in 20) is neutral to litmus paper and is dextrorotatory.

The specific rotation $[\alpha]_D$ of Dextrose determined at 25° C. in an aqueous solution containing in each 100 cc. 10 Gm. of Dextrose, previously dried to constant weight at 100° C. and using a 200 mm. tube, is not less than +52.5° and not more than +53.0°. The solution must be allowed to stand twenty-four hours before observing the rotation, page 1524.

Add a few drops of its aqueous solution (1 in 20) to 5 cc. of hot alkaline cupric tartrate T.S.: a copious red precipitate of cuprous oxide is formed (*difference from sucrose*).

Tests for Purity—Dextrose loses not more than 10 per cent when dried to constant weight at 105° C.

Ash: not more than 0.1 per cent.

One Gm. of finely powdered Dextrose dissolves completely on boiling with 15 cc. of alcohol under a reflux condenser (*dextrin, lactose*).

Add 1 drop of iodine T.S. to a solution of 1 Gm. of Dextrose in 10 cc. of distilled water: the liquid is colored yellow (*soluble starch, sulphite*).

Its aqueous solution (1 in 20) meets the requirements of the test for *heavy metals*, page 1519.

Dissolve 1.5 Gm. of Dextrose in 5 cc. of distilled water, add 5 cc. of diluted sulphuric acid and 1 cc. of bromine T.S., and heat for five minutes on a water bath. Add 0.5 Gm. of potassium iodide, follow with five drops of stannous chloride T.S., cool, and test for *arsenic*, page 1512. The stain produced, if any, is not greater than that produced in a test made with the same quantities of reagents and 2 cc. of the standard arsenic solution, page 1512.

Two Gm. portions of Dextrose show no more *chloride* than 0.5 cc. of fiftieth-normal hydrochloric acid, and no more *sulphate* than 0.5 cc. of fiftieth-normal sulphuric acid, page 1520.

Preserve in well-closed containers.

Uses—Dextrose is a readily absorbed food. It may be administered in the form of enemas. It is also useful for parenteral alimentation, by hypodermic and intravenous injection. Such injections also supply fluid, sustain the blood volume temporarily, and produce diuresis. They have been proposed for use in infectious diseases, and may have some value as food and as a means of introducing fluid, although they do not directly influence the course of the

infection. It may be added to the acacia solutions which are used in hemorrhage and shock. Dextrose is used in the determination of sugar tolerance.

Dose—Six ounces (180 Gm.) daily. Intravenously, from 250 to 300 cc. of a 10 to 15 per cent solution in water or, physiological solution of sodium chloride, sterilized by boiling or in an autoclave. As an enema, from a 5 to 12 per cent solution is used.

SUCROSUM. U. S. Sucrose

[**Sucros.**—Saccharum U. S. P. IX, Sugar, Cane Sugar, Beet Sugar]

A sugar [$C_{12}H_{22}O_{11}$ = 342.24] obtained from *Saccharum officinarum* Linné (Fam. *Gramineæ*) and other sources.

Preparation—Sucrose or sugar is prepared commercially from the sugar cane, beet root, and sorghum. Formerly, sugar cane was the only source; but at present the root of *Beta vulgaris* is largely used in Europe, and to an increasing degree in this country, for making sucrose. From the rapid growth of this industry there is a prospect of its supplanting all others. Sucrose was formerly prepared as follows: The sugar cane was crushed, and the juice, amounting to about 80 per cent, expressed; this was then heated, a little lime and calcium bisulphite added, strained, and the liquid quickly evaporated, cooled, and stirred. The thick liquid was transferred to casks perforated at the bottom, and the crystals drained. Sugar made in this way was called "open pan" sugar. It is now almost completely displaced by "vacuum pan" sugar.

In the production of *raw sugars* by the vacuum pan process, the juice, after "defecation" with lime and removal of excess of lime by carbonic acid gas, is run into vacuum pans for concentration and the saccharine juice is evaporated in this until it begins to crystallize. After the crystallization is complete, the warm mixture of crystals and syrup is run into centrifugals, in which the crystals of raw sugar are drained and dried. The syrup resulting as a by-product from raw sugar is known as molasses. Raw beet sugar is made by a similar process, but is more troublesome to purify than that made from sugar cane.

The refined sugar from either raw cane or beet sugar is prepared by dissolving the raw sugar in water, clarifying, filtering, and finally decolorizing the solution by passing it through bone black filters. The water-white solution is finally evaporated under reduced pressure to the crystallizing point and then forced to crystallize in small granules which are collected and drained in a centrifuge.

The best sugar for pharmaceutical uses is known technically as "granulated". A sugar of very high purity, obtained by crystallizing the first runnings from the charcoal filters, is now largely used in preparing pharmaceutical syrups. It is sold under various trade names as *Druggists' Standard*, *Special Standard Granulated*, and *Confectioner's Granulated* and produces a syrup which is practically free from yellow tint (see Syrups, page 261). *Loaf-sugar* or *lump sugar* is generally pure, but if kept in a damp atmosphere, it is liable to absorb moisture, and if kept in a very dry air, will lose weight. For making troches, *lozenge sugar* or *"XXXX sugar"* a very pure, finely powdered sugar, is now generally available. *"Pulverized sugar"*, as it is called, is unfitted for such a purpose.

When sugar is crystallized in regular, large, monoclinic prisms, it is called *rock-candy*, and has the specific gravity 1.606. The official test excludes sugar which contains ultramarine; this was formerly added by refiners to save the expense of using bone-black. A sugar blued by ultramarine is readily detected, for the syrup is slightly yellow, and a sediment is deposited.

Sugar in dilute aqueous solution is converted into alcohol, carbon dioxide, and eventually acetic acid, if exposed to warm, dust laden air.

Sucrose may be distinguished from grape sugar by Trommer's test, which consists in the use of copper sulphate and caustic potash. If a solution of cane sugar is mixed with a solution of copper sulphate, and potassium hydroxide added in excess, a deep blue liquid is obtained, which on being heated deposits, after a time, a little red powder. A solution of grape sugar, similarly treated, yields, by heat, a copious greenish precipitate, which rapidly changes to scarlet, and eventually to dark red. When heated to 185° C., cane sugar melts into a viscid, colorless liquid, which on being suddenly cooled forms a transparent amorphous mass, called *barley sugar*. At a higher temperature, between 204.4° and 215.5° C., it loses two molecules of water, and is converted into a very thick, black liquid, called *caramel*, which is used largely for coloring aqueous or hydro-alcoholic liquids and is now official in the N. F. (see page 844). At a still higher heat it yields combustible gases, carbonic acid, empyreumatic oil, and acetic acid, and there remains about one-fourth of its weight of charcoal, which burns without residue.

The valuation of sugars and syrups is made through the use of the polariscope (see the U. S. P. test).

There are no tests by which cane sugar and beet sugar can be distinguished from each other in the refined product.

Description and Physical Properties—White, hard, dry crystals or blocks, or a white, crystalline powder. It is odorless, has a sweet taste, and is stable in the air.

One Gm. of Sucrose is soluble in 0.5 cc. of water and in 170 cc. of alcohol, at 25° C. One Gm. is soluble in slightly more than 0.2 cc. of boiling water. It is insoluble in chloroform and in ether.

Tests for Identity and Purity—The specific rotation $[\alpha]_D$ of Sucrose determined at 20° C. in an aqueous solution containing in each 100 cc. 26 Gm. of Sucrose, previously dried to constant weight at 105° C. and using a 200 mm. tube, is not less than +65.9°, page 1524.

An aqueous solution of Sucrose (1 in 20) is neutral to litmus paper.

Ash: not more than 0.05 per cent.

An aqueous solution of Sucrose (1 in 1) is colorless or at most only faintly yellow when viewed horizontally against a white background through a vertical cylinder of colorless glass having an inside diameter of about 25 mm. When kept in large, well-closed, and completely filled bottles, the solution deposits no sediment on prolonged standing (*insoluble salts, ultramarine or Prussian blue*).

Its aqueous solution (1 in 10) is not affected by the addition of an equal volume of hydrogen sulphide T.S. (*heavy metals*). Ten cc. portions of the solution (1 in 10), remain clear for at least one minute after the addition of 1 cc. of silver nitrate T.S. (*chloride*) or of ammonium oxalate T.S. (*calcium*).

A 5 Gm. portion of Sucrose shows no more *sulphate* than corresponds to 0.3 cc. of fiftieth-normal sulphuric acid, page 1520.

Dissolve 20 Gm. of Sucrose in enough distilled water to make 100 cc. and filter the solution if necessary. To 50 cc. of the clear liquid, contained in a 250 cc. beaker, add 50 cc. of alkaline cupric tartrate solution, heat the mixture at such a rate that approximately four minutes are required to bring it to the boiling point, and boil for exactly two minutes. Add 100 cc. of cold, recently boiled distilled water, and collect and weigh the precipitated cuprous oxide in the following manner:

Prepare a Gooch crucible with an asbestos layer. Thoroughly wash the asbestos with distilled water, followed successively by 10 cc. of alcohol and 10 cc. of ether, dry at 100° C. for thirty minutes, and weigh the prepared crucible. Filter the precipitated cuprous oxide through the crucible thus prepared, thoroughly wash the residue on the filter with hot distilled water, then with 10 cc. of alcohol, and finally with 10 cc. of ether, and dry it at 100° C. The weight of the cuprous oxide does not exceed 0.155 Gm. corresponding to not more than 0.5 per cent of invert sugar.

U. S. P. Preparations—Used in preparing syrups and also in Ferri Carbonatis Saccharatus; Massa Ferri Carbonatis; Pilulæ Ferri Carbonatis; Pulvis Cretæ Compositus; Pulvis Glycyrrhizæ Compositus; Syrupus; Trochisci Acidi Tannici; Trochisci Ammonii Chloridi.

N. F. Preparations—Confectio Rosæ; Confectio Sennæ; Dentifricium; Elixirs; Ferri Oxidum Saccharatum; Infusum Rosæ Compositum; Lac Fermentatum; Misturæ; Oleosacchara; Pilulæ Ferri Iodidi; Pulvis Cretæ Aromaticus; Stili Acidi Salicylici Dilubiles; Tabellæ; Tinctura Vanillæ; Troches.

Uses—Sucrose is used principally in pharmacy for making syrups, troches, masses, confections, etc., as already noted.

Aromatic sugars may be prepared by pouring an alcoholic tincture of the spice drugs—cinnamon, cloves, etc.,—over granulated sucrose, and drying the product by exposing it to the air.

LACTOSUM. U.S. Lactose

[Lactos.—Saccharum Lactis U.S.P. IX., Milk Sugar, Sugar of Milk]

A sugar [$C_{12}H_{22}O_{11}.H_2O = 360.25$] obtained from cow's milk.

Preparation—Sugar of milk is prepared by the addition of diluted hydrochloric acid to skim milk to precipitate the casein. After the removal of the casein by filtration, the remaining albuminous matter is coagulated by heating; this is filtered out and the liquid set aside to crystallize. Animal charcoal is used to decolorize the solution in a manner similar to that used in purifying sucrose.

Description and Physical Properties—White, hard, crystalline masses, or a white powder, producing a gritty sensation on the tongue. It is odorless, and has a faintly sweet taste. It is stable in the air, but readily absorbs odors.

One Gm. of Lactose is soluble in 4.9 cc. of water at 25° C., also in 2.6 cc. of boiling water. It is very slightly soluble in alcohol; insoluble in chloroform and in ether.

Tests for Identity—The specific rotation $[\alpha]_D$ of Lactose determined at 25° C. in an aqueous solution containing in each 100 cc. 10 Gm. of Lactose, previously dried to constant weight at 80° C., and using a 200 mm. tube, is not less than +52.2° and not more than +52.5°, page 1524. The solution must be allowed to stand overnight before observing the rotation.

Add an equal volume of sodium hydroxide T.S. to 5 cc. of a hot, saturated, aqueous solution of Lactose, and gently warm the mixture; the liquid turns yellow and finally brownish-red. On the subsequent addition of a few drops of cupric sulphate T.S., a precipitate of cuprous oxide forms.

Tests for Purity—An aqueous solution of Lactose (1 in 20) is neutral to litmus paper.

Ash: not more than 0.1 per cent.

A solution of 3 Gm. of Lactose in 10 cc. of boiling distilled water is clear, colorless, and odorless.

Add 20 cc. of 70 per cent (by volume) alcohol to 2 Gm. of finely powdered Lactose, shake the mixture frequently during half an hour at 15° C., and filter: a 10 cc. portion of the filtrate remains clear after mixing with an equal volume of dehydrated alcohol (*dextrin*), and this liquid upon evaporation on a water bath leaves not more than 0.03 Gm. of residue (*sucrose or glucose*).

An aqueous solution of Lactose (1 in 20) meets the requirements of the test for *heavy metals*, page 1519.

Boil 1 Gm. of powdered Lactose with 50 cc. of distilled water, cool, and add a drop of iodine T.S.: no blue color is produced (*starch*).

Preserve in tightly-closed containers.

U. S. P. Preparations—Ferri Carbonas Saccharatus; Pulvis Ipecacuanhæ et Opii; Triturations.

N. F. Preparation—Pepsinum Saccharatum.

Uses—Lactose, more commonly known as sugar of milk, is a useful diluent, and is largely used in medicine and pharmacy. The hardness of the crystals has been used as an assistance in securing thorough admixture of the ingredients in compound powders, by necessitating prolonged trituration, but today the powder is almost always used.

MEL. U.S. Honey

[Replacing Mel Depuratum U.S.P. IX, Clarified Honey]

A saccharine substance, gathered mostly from the nectaries of flowers, and deposited in the honeycomb by the bee, *Apis mellifera* Linné (Fam. *Apidæ*). It must be free from foreign substances such as parts of insects, leaves, etc.

The nectaries of flowers contain a sweet substance, which is extracted by the bees and stored up in the hive in what are known as the honeycombs, which are composed of beeswax (see yellow wax, page 1191). Large quantities of honey are obtained from California, the Southern States, and the West Indies. Before the passage of the Food and Drugs Act, large amounts of artificial honey were manufactured from glucose by flavoring and coloring, but the rigid enforcement of this law has practically eliminated the spurious article from the market.

Description and Physical Properties—A thick, syrupy liquid of a light yellowish or yellowish-brown color. It is translucent when fresh, but frequently becomes opaque and granular from crystallization of dextrose. It has a characteristic odor and a sweet, faintly acrid taste.

Tests for Identity and Purity—Honey is lævorotatory at 20° C. and is slightly acid to litmus paper.

Diluted with twice its weight of water, Honey is only moderately turbid, is not stringy, and has a specific gravity of not less than 1.099 at 25° C.

Incinerate about 2 Gm. of Honey, accurately weighed, at a low temperature in a platinum crucible, in small portions at a time: not more than 0.3 per cent of ash remains.

A solution of 10 Gm. of Honey in 50 cc. of distilled water requires not more than 0.5 cc. of normal sodium hydroxide for neutralization, phenolphthalein T.S. being used as indicator.

Ten cc. portions of a filtered aqueous solution of Honey (1 in 10) show no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid and no more *sulphate* than corresponds to 0.2 cc. of fiftieth-normal sulphuric acid, page 1520.

Boil about 2 Gm. of Honey with 20 cc. of water, cool, and add two drops of iodine T.S.: no blue, green, or reddish color is produced (*starch or dextrins*).

The color of an aqueous solution of Honey (1 in 2) is not immediately changed when mixed with an equal volume of ammonia T.S. (*foreign coloring matter*), and a 5 cc. portion does not at once acquire a red or rose color on the addition of a few drops of hydrochloric acid (*azo dyes*).

Triturate about 1 Gm. of Honey with 20 cc. of ether in a mortar, filter into a porcelain dish or crucible, allow the ether to evaporate, and add to the residue one drop of resorcinol T.S. At most only a pink color is produced, which disappears in half a minute, but not an orange, cherry or brown-red color (*artificial honey or added invert sugar*).

For many years the Pharmacopœia included a process for clarifying honey which consisted of mixing the crude honey with paper pulp, heating to 70° C., removing the scum from the surface, adding water to restore the volume, straining, and finally mixing with 5 per cent of glycerin. The Food and Drugs Act requirements have ensured the production of ample quantities of pure, high-grade honey, mostly separated from the comb by centrifuging so that the heating process is no longer required.

History—Honey is one of the oldest of food and medicinal products and has been in use as a vehicle for disguising medicines since before the days of Tut-ank-Amen. Many curious theories were held as to its origin. It was credited with many medicinal virtues of its own during the sixteenth and seventeenth centuries when it was recommended as a cure for almost everything from baldness to worms.

U. S. P. Preparations—Hydrargyrum cum Creta; Massa Ferri Carbonatis; Mel Rosæ.

N. F. Preparations—Confectio Rosæ; Elixir Manacæ Compositum; Gargarisma Guaiaci Compositum; Mel Sodii Boratis; Oxymel Scillæ; also as an excipient in pills.

MANNA. U. S. Manna

Manna is the dried exudation of *Fraxinus Ornus* Linné (Fam. *Oleaceæ*).

Manna yields not less than 75 per cent of anhydrous alcohol-soluble extractive, when extracted with boiling 90 per cent alcohol, by volume.

Description and Physical Properties—In irregular, more or less elongated, flattened, 3-sided pieces; externally yellowish-white; friable; internally nearly white, porous and crystalline in appearance; odor slight, but characteristic; taste sweet, slightly bitter, and faintly acrid. Also in irregular masses, consisting in part of brittle or soft fragments from yellowish-white to yellowish-gray in color. The quantity of these yellowish-white fragments must not be less than 40 per cent of the whole.

Assay—Proceed as directed under alcohol-soluble extractive, page 1523 using boiling 90 per cent alcohol, by volume, and filter rapidly through purified cotton while hot, washing the cotton with boiling alcohol.

N. F. Preparations—Infusum Sennæ Compositum; Syrupus Mannæ.

This substance, which is found in commerce of varying quality, is, when pure, soluble in three parts of cold water and in its own weight of boiling water. It separates in crystalline masses from a boiling, saturated, aqueous solution. It is partially soluble in alcohol. The assay is based upon the solubility of mannite in 90 per cent alcohol.

Mannite, the principal constituent, is white, inodorous, crystallizable in semi-transparent needles, of a sweetish taste, soluble in five parts of cold water, scarcely soluble in cold alcohol, but readily dissolved by that liquid when hot, and deposited when it cools. Its composition is $C_6H_{14}O_6$, and it is considered

as belonging to the class of *hexatomic alcohols*. Mannite is found in many plants, and may be converted by oxidation into mannose, a fermentable sugar.

Uses—Manna is used as a laxative, and often added to senna leaves to make a cathartic infusion. The dose is from one-half to two ounces (15.5 to 62 Gm.).

GLYCYRRHIZA. U.S. Glycyrrhiza

[**Glycyrrh.**—Licorice, Liquorice Root, Sweetwood, Italian Juice Root, Liquorice Root, Spanish Juice Root]

Glycyrrhiza is the dried rhizome and roots of *Glycyrrhiza glabra* Linné var. *typica* Regel et Herder, known in commerce as Spanish Licorice, or of *Glycyrrhiza glabra* Linné var. *glandulifera* Regel et Herder, known in commerce as Russian Licorice, or of other varieties of *Glycyrrhiza glabra* Linné yielding a yellow and sweet wood (Fam. *Leguminosæ*).

Glycyrrhiza yields not more than 2.5 per cent of acid-insoluble ash.

Description and Physical Properties—*Unground Spanish Licorice*—Nearly cylindrical, the upper portion more or less knotty; usually in pieces from 14 to 20 cm. or more in length and from 5 to 20 mm. in thickness; externally yellowish-brown or dark brown, longitudinally wrinkled, the thinner rhizomes often having prominent alternate buds, the thicker rhizomes having distinct corky patches; fracture coarsely fibrous; internally yellow, radiate; odor distinctive; taste sweetish and slightly acrid.

Unground Russian Licorice—Nearly cylindrical, somewhat tapering, sometimes split longitudinally, from 15 to 30 cm. in length and from 1 to 5 cm. in diameter; when deprived of the outer corky layer, it is externally pale yellow; fracture coarsely fibrous; internally pale yellow; wood radially cleft; odor distinct; taste sweetish.

For further description see the U. S. P. X.

U. S. P. Preparations—Extractum Glycyrrhizæ; Extractum Glycyrrhizæ Purum; Fluidextractum Cascaræ Sagradæ Aromaticum (from Extract); Fluidextractum Glycyrrhizæ; Massa Hydrargyri; Mistura Glycyrrhizæ Composita (from Fluidextract); Pulvis Glycyrrhizæ Compositus; Syrupus Sarsaparillæ Compositus (from Fluidextract); Trochisci Ammonii Chloridi.

N. F. Preparations—Elixir Glycyrrhizæ Aquosum (from Fluidextract); Elixir Taraxaci Compositum (from Fluidextract); Fluidglyceratum Cascaræ Sagradæ Aromaticum; Fluidglyceratum Glycyrrhizæ; Fluidextractum Trifolium Compositum; Fluidextractum Sarsaparillæ Compositum; Pilulæ Ferri Iodidi; Species Pectorales; Syrupus Glycyrrhizæ (from Fluidglycerate); Tinctura Aloes; Tinctura Aloes et Myrrhæ; Tinctura Rhei Dulcis.

This well-known root contains the sweet principle *glycyrrhizin*, or *glycyrrhizic acid*, $C_{44}H_{63}O_{18}N$. This was found by Roussin to exist in the root in combination with ammonia. The amount present in glycyrrhiza varies greatly and no official standard or assay has been adopted.

The following assay method has been suggested by Percy A. Houseman and is modeled after the method of Parry:

Assay—Dissolve 2 Gm. of Glycyrrhiza in 10 cc. of hot water, in a centrifuge tube. After cooling add 20 cc. of 80 per cent alcohol, and then gradually 50 cc. of 95 per cent alcohol. After standing two hours centrifuge the contents of the tube, stir the residue twice with 80 per cent alcohol, and again in centrifuge. Pour off the liquid, and evaporate to dryness on a water bath in a vacuum. Transfer the evaporated residue, with 30 cc. of water, to a small Erlenmeyer flask, cool at 15° C., and precipitate the glycyrrhizin with 3 cc. of dilute sulphuric acid (10 cc. of acid to 300 cc. of water). After standing for two hours, cool the contents of the beaker for half an hour on ice, and pour the clear liquid through a small filter. Wash the glycyrrhizic acid with ice water four times by decantation and transfer the precipitated acid remaining in the flask and on the filter to a tared dish, by dissolving it in diluted alcohol to which has been added two drops of 5 per cent ammonia water to neutralize traces of sulphuric acid. Evaporate to constant weight and weigh.

There is present in Glycyrrhiza an oleoresinous substance to which its slight acridity is due. If alcohol or an alkali is used as a menstruum for the root and the preparation not treated to deprive it of acridity, it will have a disagreeable after-taste. For this reason the U. S. P. has adopted boiling water for its extraction in both the extract and the fluidextract.

Uses—Glycyrrhiza is valuable in pharmacy chiefly on account of the sweet principle. It is one of the most efficient substances known for masking the taste of bitter substances, like quinine. Acids precipitate the glycyrrhizin and should not be added to mixtures in which glycyrrhiza is intended to mask the disagreeable taste. It is used in a number of official preparations (see page 900).

Average dose—30 grains (2 Gm.).

Unofficial Glycyrrhiza Preparation

GLYCYRRHIZINUM AMMONIATUM. U. S. P. IX **Ammoniated Glycyrrhizin**

A sweet principle, combined with ammonia, obtained from glycyrrhiza.

Ammoniated Glycyrrhizin was official for many years, but although a valuable flavor it was rarely prescribed, the extract or fluidextract being preferred. It is made by percolating 500 Gm. of ground glycyrrhiza, with a mixture of 175 cc. of water and 25 cc. of ammonia water, and then with water, to obtain 500 cc. of percolate. Sulphuric acid is then added slowly to the percolate until completely precipitated. This precipitate of glycyrrhizin is then washed with cold water, again dissolved in ammonia water, diluted with an equal volume of water, and the solution spread upon plates of glass, so that when dry, the product may be obtained in scales.

Physical Description—Dark brown or brownish-red scales, without odor, and having a very sweet taste. It is freely soluble in water and soluble in alcohol.

Uses—This compound is useful in elixirs, syrups, etc., whenever the flavor of glycyrrhiza is desired. It is especially valuable when mixed with bitter or disagreeable powders to mask their taste.

TRITICUM. N. F. **Triticum**

(U. S. P. IX)

[**Tritic.**—Couch Grass, Dog Grass]

Triticum consists of the dried rhizome and roots of *Agropyron repens* (Linné) Beauvois (Fam. *Graminæ*).

Triticum contains not more than 2 per cent of foreign organic matter and yields not more than 3 per cent of acid-insoluble ash.

Description—Rhizome; usually in pieces from 4 to 12 mm. in length and from 1 to 2.5 mm. in diameter; externally light yellow or yellowish-brown, longitudinally furrowed, smooth, lustrous, nodes with circular leaf-scars, a few root-scars and occasional slender roots; fracture tough, fibrous internally lemon-yellow and with a large, hollow pith. Roots filiform, irregularly branching, attaining a length of about 5 cm. and not more than .05 mm. in thickness, light-brown or yellowish-brown, frequently covered with long root hairs. Odor slight, aromatic; taste sweetish.

For further description see the N. F. V.

U. S. P. Preparation—Fluidextractum Tritici.

N. F. Preparations—Elixir Sabal et Santali Compositum; Fluidextractum Tritici.

Triticum is usually found in the market cut into small sections. It contains triticin, a principle resembling inulin, also glucose, levulose, etc.

Uses—It is used in inflammatory conditions of the urinary organs in the dose of two and one-half drachms (10 Gm.), usually administered in the form of an infusion.

CHAPTER LXIV

ALCOHOLS AND THEIR DERIVATIVES INCLUDING A DISCUSSION OF YEAST, FERMENTATION, AND ENZYMES

The influence of minute amounts of chemical substances in accelerating the speed of reactions has long been known in inorganic chemistry, such compounds being called catalysts. The use of manganese dioxide in hastening the liberation of oxygen from potassium chlorate is an example, as is also the use of platinum black in the contact process for making sulphuric acid.

Catalysis has been defined by Ostwald as "the acceleration of a chemical change by the presence of some foreign substance".

In animal and plant physiology similar catalytic changes are known, and the catalytic substances are called *enzymes.*

Many enzymes have been identified and studied. The phenomena commonly called fermentation and putrefaction are examples of changes produced by enzymes.

Formerly these two terms were used loosely and unscientifically. A clarification of the nomenclature has been accomplished by classifying such catalytic changes as affect carbohydrates as *fermentation,* while the changes produced in proteins are called *putrefaction.* The enzymes as a class, however, are frequently referred to as ferments. Formerly ferments were classified as *organized* and *unorganized* and the latter were called "*cryptolytes*" but no such distinction is made any longer.

The classification of enzymes is very comprehensive and includes the following groups:

Hydrolytic enzymes

a. Fat-splitting enzymes (esterases), as *lipase.*
b. Carbohydrate-splitting enzymes (carbohydrases), as *invertase, maltase, lactase, amylase* (*diastase*), *inulase, pectinase,* and *cytase.*
c. Glucoside-splitting enzymes, as *emulsin, myrosin,* and *phytase.*
d. Protein-splitting enzymes (proteases) as *pepsin, trypsin, erepsin, bromelin,* and *papain.*
e. Urea-splitting enzymes, as *urease.*

Fermenting enzymes

a. Producing alcoholic fermentation, as *zymase.*
b. Producing lactic fermentation, as *lactic acid-forming* bacteria.
c. Producing butyric fermentation, as *butyric acid-forming* bacteria.

Coagulating enzymes

a. Milk-curdling enzymes, as *rennin.*
b. Blood-coagulating enzymes, as *thrombin.*
c. Pectin-coagulating enzymes, as *pectase.*

Oxidizing enzymes

a. Converting alcohol to acetic acid, as *mycoderma aceti.*
b. Liberating oxygen from peroxides as *catalase* or *peroxidase.*

Enzymes are sometimes described in general terms as *amylolytic, proteolytic,* etc. The correctness of such terms has been questioned and as substitutes the terms *amyloclastic, proteoclastic,* etc., have been suggested.

It will be readily appreciated that many important physiological processes in plants as well as in animals are dependent upon enzyme action. The industrial applications of enzyme action are very numerous, as in the production of such important substances as alcohol, acetic acid, etc.

The chemical constitution of enzymes is unknown, as none has yet been isolated in a pure state.

Enzymes as a rule are very sensitive to heat and light. All enzymes are destroyed at 100° C. and many are affected at as low a temperature as 60° C. Most enzymes are colloidal in character.

The action of many enzymes is retarded or destroyed by the presence of antiseptics. The production of alcohol by the action of zymase upon sugar may be represented by chemical reactions which are apparently very simple, but which in reality are very complex.

Sucrose is not directly fermentable. It must first be changed to monosaccharides by invertase, by the following reaction:

$$\underset{\text{sucrose}}{C_{12}H_{22}O_{11}} + \underset{\text{water}}{H_2O} = \underset{\text{dextrose}}{C_6H_{12}O_6} + \underset{\text{levulose}}{C_6H_{12}O_6}$$

The monosaccharides, dextrose and levulose, are then acted upon by zymase according to the following reaction:

$$\underset{\text{dextrose}}{C_6H_{12}O_6} = \underset{\text{alcohol}}{2C_2H_5OH} + \underset{\text{carbon dioxide}}{2CO_2}$$

Both invertase and zymase occur in yeast.

The intermediate changes that occur in the latter reaction are very complex, and the following substances are reported as being produced at different stages of the process: *glyceric aldehyde*, *dihydroxyacetone*, *methyl glyoxal*, *pyruvic acid*, *acetic aldehyde*, and *glycerol* (glycerin).

If starchy substances are used as the starting point for alcoholic fermentation, the starches must first be gelatinized and then hydrolyzed to sugars by the action of an amylase, such as malt diastase, as in the following reaction:

$$\underset{\text{starch}}{C_6H_{10}O_5} + \underset{\text{water}}{H_2O} = \underset{\text{dextrose}}{C_6H_{12}O_6}$$

Here again the condensed reaction does not begin to show the actual changes that take place, for among the intermediate products formed are *dextrins* (*amylodextrin*, *erythrodextrin*, and *achroödextrin*) and maltose.

If a liquid in which alcoholic fermentation has occurred is not properly preserved or if the alcoholic content is very low, subsequent fermentation of a different character ensues in which the alcohol is converted into acetic acid through the influence of the microscopic organism known as *mycoderma aceti*.

This reaction is also expressed in a simple form as:

$$\underset{\text{alcohol}}{C_2H_5OH} + \underset{\text{oxygen}}{O_2} = \underset{\text{acetic acid}}{CH_3COOH} + \underset{\text{water}}{H_2O}$$

Here also intermediate reactions take place—*aldehyde* being one of the products formed.

The most important derivative of sugar through the action of a ferment is alcohol. This is usually obtained from whisky or from fermented molasses, by distillation.

The distilled product of vinous liquors forms the different ardent spirits of commerce. When obtained from wine, it is called *brandy* from the German *branntwein* (*burned wine*); from fermented molasses, *rum*; from malted barley,

rye, corn, wheat or other grains, *whisky*, from the Gaelic *usquebaugh*; from malted barley and rye-meal, with hops, and rectified from juniper berries, *gin*; and from fermented rice, *arrack*. These spirits are of different strengths—that is, they contain different proportions of alcohol—and have various peculiarities by which they are distinguished, chiefly the odor and taste. The manufacture and dispensing of these alcoholic liquors is only permitted under the regulations of the Internal Revenue Department and the National Prohibition or Volstead Act (see page 1261).

The compounds derived from sugars will be considered under the following sub-heads: 1. Ethyl hydroxide and oxide and their preparations. 2. Preparation of the esters of the ethyl, methyl, and amyl series. 3. Aldehyde, its derivatives and preparations.

Yeast is official in the N. F. for the making of fermented milk (see page 1182). It is described as follows:

CEREVISIÆ FERMENTUM COMPRESSUM. N. F. **Compressed Yeast**
[Cerev. Ferm. Compr.]

Compressed yeast consists of the moist, living cells of *Saccharomyces cerevisiæ* Meyen or of other species of *Saccharomyces*, (Fam. *Saccharomycetaceæ*) combined with a starchy or absorbent base.

Yeast contains at least two enzymes. Invertase changes sucrose to monosaccharides and zymase converts monosaccharides to alcohol. Yeast also contains an abundance of vitamin C.

Official Description—White or yellowish-white, soft and easily broken masses, having a characteristic, slightly sour odor, and not more than a faintly acid reaction to litmus.

When examined under the microscope, numerous oidium and mycoderma cells and starch grains are visible.

Compressed yeast must not be used unless fresh, and free from mildew and musty or foul odors.

N. F. Preparation—Lac Fermentatum.

Uses—Yeast has a laxative action. It is also supposed to increase the resistive powers of the body against infections and is used in acne, boils, etc.

Ethyl Hydroxide and Oxide and Their Preparations

ALCOHOL DEHYDRATUM. U. S. **Dehydrated Alcohol**
[Alcohol Dehyd.—Alcohol Absolutum, Dehydrated Ethanol]

Dehydrated Alcohol contains not less than 99 per cent by weight of C_2H_5OH (88.12).

Preparation—The natural sources of alcohol are starch and sugar as they exist in various plants, and alcohol, if pure, is the same from whatever source it is derived. It is generally made by distilling a crude grain spirit as in making whisky, and redistilling and rectifying the distillate in a special apparatus. The yield of alcohol, sp. gr. 0.835, obtained from good whisky is about 58 per cent by volume. The principal impurity is *fusel oil*, or amylic alcohol. Alcohol may be deprived of odor by treating it with potassium permanganate and redistilling. *Absolute alcohol* is the name formerly given to the strongest alcohol which can be distilled, and the name implies absolute freedom from water. This is an impossible achievement and the most appropriate name for this product is not absolute alcohol, but dehydrated alcohol. Owing to the very strong affinity existing between alcohol and water, the strongest alcohol that can be made by simple distillation contains about fifteen per cent of water, by volume. At 78° C. alcohol forms a constant boiling mixture with water which distils at the above concentration. An alcohol of greater strength may be obtained by the use of a column and still (see page 144), but in order to free it from the last 5 to 8 per cent of water it is necessary to use some substance

having a still stronger affinity for water. This is found in recently burned lime, and the method employed is to percolate the strongest and purest alcohol attainable through the lime, out of contact with air, and then to redistil the percolate *in vacuo*. In this way alcohol may be obtained having a specific gravity as low as 0.79355 at 15.56° C. (60° F.). (Squibb.) The official description for dehydrated alcohol of not less than 99 per cent strength is as follows:

Description and Physical Properties—A transparent, colorless, mobile, and volatile liquid, having a characteristic odor, and a burning taste. It is very hygroscopic.

Tests for Identity and Purity—Specific gravity: not above 0.798 at 15.56° C. (the U. S. Government standard temperature for Alcohol).

Shake 10 cc. of Dehydrated Alcohol in a stoppered tube with about 0.5 Gm. of powdered anhydrous cupric sulphate: the latter does not become blue (*water*).

In other respects dehydrated Alcohol has the properties of and complies with the tests for purity under *Alcohol*.

Preserve in well-closed containers, in a cool place, remote from fire.

N. F. Preparation—Liquor Phosphori.

ALCOHOL. U. S. Alcohol
[Ethanol]

Alcohol contains not less than 92.3 per cent by weight, corresponding to 94.9 per cent by volume, at 15.56° C., of C_2H_5OH (88.12).

Alcohol burns with a pale flame without residue, the products being carbon dioxide and water.

Alcohol is official in three forms: dehydrated alcohol, sp. gr. 0.798 at 15.56° C., 0.790 at 25° C.; alcohol, sp. gr. 0.816 at 15.56° C., 0.810 at 25° C.; diluted alcohol, sp. gr. 0.935 to 0.937 at 15.56° C., 0.930 to 0.932 at 25° C. The temperature at which the specific gravity of alcohol is taken for official preparations is exceptional, the old temperature 15.56° C. (60° F.) being retained because the United States Internal Revenue Department uses this temperature for its standards.

Deodorized alcohol was the official title in 1890 for the quality of alcohol now official. The description of alcohol, U. S. P., is as follows:

Description and Physical Properties—A transparent, colorless, mobile, and volatile liquid. It has a slight, characteristic odor, and a burning taste. It is inflammable.

Alcohol is miscible with water without any trace of cloudiness; also miscible with ether and with chloroform.

Tests for Identity and Purity—Specific gravity: not above 0.816 at 15.56° C. (the U. S. Government standard temperature for Alcohol).

Alcohol is readily volatilized even at low temperatures and boils at about 78° C.

Alcohol diluted with an equal volume of distilled water does not affect the color of blue or red litmus paper previously moistened with water.

Evaporate 40 cc. of Alcohol in a platinum or porcelain dish on a water bath, and dry at 100° C.: the residue does not exceed 0.001 Gm.

Mix 10 cc. of Alcohol with 5 cc. of distilled water and 1 cc. of glycerin, and allow the mixture to evaporate spontaneously from clean, odorless blotting paper: no foreign odor is perceptible when the last traces of the Alcohol leave the paper (*fusel oil constituents*).

Allow 25 cc. of Alcohol to evaporate spontaneously in a porcelain dish carefully protected from dust, until the surface of the dish is barely moist: no red or brown color is produced upon the addition of a few drops of sulphuric acid (*amyl alcohol or non-volatile, carbonizable organic impurities, etc.*).

On mixing 10 cc. of Alcohol in a test tube with 5 cc. of potassium hydroxide T.S., the liquid does not at once assume a yellow color (*aldehyde or oak tannin*).

Shake 20 cc. of Alcohol in a clean, glass-stoppered bottle with 1 cc. of silver nitrate T.S. and allow the mixture to stand in diffused daylight for 6 hours: the mixture does not become more than faintly opalescent, or acquire more than a faint brownish tint (*organic impurities, aldehyde, etc.*).

Dilute Alcohol with water to contain about 5 per cent by volume of ethyl alcohol. To 5 cc. of this dilute alcohol contained in a test tube of 20 cc. capacity, add 0.5 cc. of phosphoric acid and 2 cc. of a 3 per cent aqueous solution of potassium permanganate, and allow the mixture to stand for ten minutes. Add 1 cc. of an aqueous 10 per cent solution of oxalic acid, and allow to stand until the liquid is a transparent brown. Now add 5 cc. of a diluted and cooled sulphuric acid, prepared by mixing 3 volumes of distilled water and 1 volume of sulphuric acid, add 5 cc. of freshly prepared fuchsin-sulphurous acid T.S., mix well, and allow to stand for ten minutes. At the

end of this time the solution, when observed against a white background, may have a reddish or pale green tint, but not a distinct blue or violet color (*methanol*).

A mixture of 5 cc. of Alcohol, 2 cc. of sodium hydroxide T.S. and five drops of a freshly prepared aqueous solution of sodium nitroprusside (1 in 50), rendered slightly acid with acetic acid, shows no violet tint within one minute (*acetone*).

Alcohol, diluted with an equal volume of water, does not respond to the tests for *alkaloids*, *diethylphthalate*, *formaldehyde*, *isopropyl alcohol*, and *phenols* described under *Spiritus Frumenti*.

Preserve in well-closed containers, in a cool place, remote from fire.

U. S. P. Preparations—Acidum Sulphuricum Aromaticum; Alcohol Dilutum; Collodium; Elixirs; in the preparation of Spirits, Tinctures, Extracts, Fluidextracts, Liniments, Resins, etc.

N. F. Preparations—Used as in the U. S. P. for many pharmaceutical operations, also in Lavatio Ori; Acetum Aromaticum, Liquor Antisepticus; Liquor Antisepticus Alkalinus.

History—The term alcohol is of Arabic origin, the word *Al-Kohl* being applied to the black antimony sulphide employed by the harem beauties to darken their eyebrows and eyelashes. The word in its original significance meant finely divided and is still used in this way in the term *alcoholized iron* which simply means finely divided iron.

Distillation was first practiced shortly after the beginning of the Christian Era in Alexandria, but no definite record occurs of strong alcoholic liquids prepared by distillation until Arnold of Villanova who wrote in the latter part of the thirteenth century and who called such a product *aqua vini* or *aqua vitæ* and extolled its virtues as "it strengthens the body and prolongs life". It is said that when Henry II invaded Ireland in the twelfth century the inhabitants were making and drinking a strongly alcoholic liquid which they called *uisge-beatha* (from the first half of which we get the name whisky) which is Gaelic for "water of life".

Uses—Alcohol is used in pharmacy principally for its solvent powers (see page 239). It is also used as the starting point in the manufacture of many important compounds, like ether, chloroform, iodoform, etc. A specially fine brand of alcohol can now be obtained which is rectified particularly for perfumers' use; it is known as *cologne* spirits. It is said to be made by diluting the cologne spirit with sufficient water to bring it to about the strength of diluted alcohol, passing this through bone black, and then redistilling and concentrating it again to the proper strength in a rectifying column and still. All alcohol for perfumery must be denatured (see page 1227). Alcohol is also largely used as a fuel, chiefly in the form of denatured alcohol (see page 94).

ALCOHOL DILUTUM. U.S. Diluted Alcohol

[Alcohol Dil.—Diluted Ethanol]

Diluted Alcohol contains not less than 41 per cent and not more than 42 per cent by weight, corresponding to not less than 48.4 per cent and not more than 49.5 per cent by volume, at 15.56° C., of C_2H_5OH.

	Metric	Alternative
Alcohol	**500 cc.**	1 pint
Distilled Water	**500 cc.**	1 pint

Measure the alcohol and water at the same temperature, and mix them. If the two liquids are measured at the temperature of 25° C., the mixture when cooled to the same temperature will measure about 970 cc.

Diluted Alcohol may also be prepared in the following manner:

	Metric	Alternative
Alcohol	**408 Gm.**	40 oz. av. 350 gr.
Distilled Water	**500 Gm.**	50 oz. av.

When equal volumes of alcohol and water are mixed together, a rise in temperature and a contraction of about 3 per cent in volume take place. In

small operations the contraction is generally disregarded, in larger operations it is very apparent. If 50 gallons of official alcohol are mixed with 50 gallons of water, the product will not be 100 gallons of diluted alcohol, but only 96¼ gallons, a contraction of 3¾ gallons. United States *Proof Spirit* differs from diluted alcohol and is stronger; it contains 50 per cent, by volume, of absolute alcohol at 15.56° C. (60° F.). This corresponds to 42.5 per cent by weight, and has a specific gravity of 0.9341 at the same temperature.[1] If spirits have a specific gravity lighter than that of "proof spirit" (0.9341) they are said to be "*above proof*" if heavier, "*below proof*".

Tests for Identity and Purity—Diluted Alcohol has a specific gravity of from 0.935 to 0.937 to 15.56° C. (the U. S. Government standard temperature for alcohol).

It complies with the purity tests under *Alcohol*, allowance being made for the difference in strength and the presence of water, the boiling point being omitted.

Preserve in well-closed containers, in a cool place, remote from fire.

Uses—Diluted alcohol is used as a menstruum in making tinctures, fluidextracts, extracts, etc. Its properties have been already fully described in connection with the various preparations. Its value consists not only in antiseptic properties, but also in its possessing the solvent powers of both water and alcohol.

Denatured Alcohol—An act of Congress of June 7, 1906, authorized the withdrawal of alcohol from bond, without the payment of the internal revenue tax, for certain clearly defined uses in the industries and arts, provided such alcohol had been mixed, under the prescribed conditions, with denaturing substances which rendered it unfit for beverage purposes.

Subsequent acts of Congress, especially since the passage of the Volstead Act, have increased the number of methods for denaturing and the uses to which the product may be applied, so that ether and chloroform are now made from suitably denatured alcohol and one of the authorized denaturing processes consists of the U. S. P. formulas for tincture of iodine and liniment of soft soap. The actual denaturing may be conducted only under Government supervision in specially licensed establishments.

Special formulas for denatured alcohol applicable to specific manufacturing operations are permitted under government supervision.

Ethyl alcohol may be sold by retail dealers holding permits to use and sell intoxicating liquors, and who have paid the tax, if the quantities do not exceed one pint, and if medicated by one of the following formulas and labeled "Poison". Its use must also be understood to be other than for internal administration.

1. Formaldehyde, 2 parts; glycerin, 2 parts; alcohol, 96 parts. 2. Carbolic acid, 1 drachm; tannic acid, 1 drachm; alcohol, 1 pint; water, 1 pint. 3. Alum, ½ ounce; formaldehyde, 2 drachms; camphor, 1 ounce; alcohol and water, each 1 pint. 4. Liquor cresolis comp. (U. S. P.), 10 cc.; alcohol, 1000 cc.

Information may be obtained from the office of the Bureau of Internal Revenue, at Washington, D. C., concerning other specially denatured alcohols

---

[1] The U. S. P. VIII gave the following rules for making an alcohol of any required lower percentage from an alcohol of any given higher percentage: I. By Volume—Designate the volume percentage of the stronger alcohol by *V*, and that of the weaker alcohol by *v*.

Rule—Mix *v* volumes of the stronger alcohol with distilled water to make *V* volumes of product. Allow the mixture to stand until full contraction has taken place, and until it has cooled, then make up the deficiency in the *V* volumes by adding more distilled water.

Example—An alcohol of 30 per cent by volume is to be made from an alcohol of 94.9 per cent by volume —Take 30 volumes of the 94.9 per cent alcohol, and add enough distilled water to produce 94.9 volumes.

II. By Weight—Designate the weight-percentage of the stronger alcohol by *W*, and that of the weaker alcohol by *w*.

Rule—Mix *w* parts by weight of the stronger alcohol with distilled water to make *W* parts by weight product.

Example—An alcohol of 50 per cent by weight is to be made from an alcohol of 92.3 per cent by weight —Take 50 parts by weight of the 92.3 per cent alcohol, and add enough distilled water to produce 923 parts by weight.

for use in the industries. Many such are permitted but authorization to use them is only granted through a special permit and under carefully regulated conditions. (See page 1261.)

The U. S. P. IX has provided alcohol tables which are useful to the pharmacist in determining the alcoholic per cent of unknown liquids. Since the Food and Drugs Act requires a statement of the alcoholic per cent of pharmaceuticals it is often necessary to determine this factor. By using the distillation method for alcoholic determination (see below) and then referring the specific gravity of the liquid to the tables on the following pages, the actual per cent of alcohol present in the liquid may readily be determined.

Alcohol Determination. U. S.

Place 25 cc. of the preparation, measured at any definite temperature between 15° and 30° C., in a distilling flask of about 200 cc. capacity, provided with a high side tube connected with a suitable condenser; add 50 cc. of distilled water, distil into a 50 cc. graduated flask, at such a rate that about 48 cc. of distillate will be received in a half hour; if volatile products other than alcohol are known to be absent, bring to the original temperature and dilute to 50 cc. with water of the same temperature.

Determine the specific gravity of the distillate at any definite temperature between 15° and 30° C. by means of a pycnometer, and find the per cent of absolute alcohol by volume by reference to the alcoholometric table (page 909), and multiply by the dilution factor to find the per cent of alcohol in the original preparation.

If the preparation is thought to contain less than 25 per cent of alcohol, 50 cc. should be used for analysis; if it is believed to contain over 50 per cent of alcohol, 10 cc. should be taken. In either case the volume of the distillate should be made up to 50 cc. as directed above.

If the preparation contains iodine, treat it with zinc dust before distilling. (Sodium thiosulphate may be used instead of zinc dust, in which case several drops of sodium hydroxide T.S. should be added to prevent sulphur compounds from distilling over.) If volatile acids are present, neutralize with sodium hydroxide T.S.; if volatile bases are present, neutralize with diluted sulphuric acid; if both volatile acids and volatile bases are present, neutralize with diluted sulphuric acid and distil about 50 cc., neutralize this distillate with sodium hydroxide T.S., add 25 cc. of distilled water, and distil once more in the manner directed above and dilute to 50 cc.

If camphor, chloroform, ether, volatile oils, or other volatile products are known or believed to be present, transfer the first distillate to a separatory funnel and saturate it with sodium chloride, add 15 cc. of petroleum benzin and shake the mixture for one or two minutes.

If glycerin is present, dilute the liquid with sufficient distilled water to insure not more than 50 per cent of glycerin remaining in the liquid left in the flask after distilling. After the liquids have completely separated, draw off the lower alcoholic salt solution into a second separator, and repeat the extraction with 15 cc. of petroleum benzin; draw off the lower alcoholic salt solution into a distilling flask of about 200 cc. capacity, wash the combined petroleum benzin solutions with about 25 cc. of saturated sodium chloride solution, and add the washings to the distilling flask. Distil into a 50 cc. graduated flask at such a rate that about 45 to 48 cc. of distillate are received within a half hour. Bring to the original temperature, dilute with water of the same temperature to 50 cc. and determine the specific gravity and alcoholic per cent as directed above.

* Barometer 760 mm. Air one-half saturated with moisture.

‖ If temperature of observation is above 15.56° C., look for percentage correction in the following table.

† Correction subtractive if barometer is above, additive if below, 760 mm. If barometer readings are in inches reduce to millimeters by multiplying by 25.4

‡ Corresponding with a difference in specific gravity of 0.0001.

§ The figures on this line across the page are for fractional percentages below 1.

Note: The figures of these alcoholometric tables are based on tables issued by the U. S. Bureau of Standards.

SPIRITUS FRUMENTI. U. S. Whisky

[Sp. Frum.—WHISKEY]

Whisky is an alcoholic liquid obtained by the distillation of the fermented mash of wholly or partly malted cereal grains, and containing not less than 47 per cent and not more than 53 per cent by volume of C_2H_5OH (88.12), at 15.56° C. It must have been stored in charred wood containers for a period of not less than four years.

Preparation—Because of the immense production of grain in this country, the cheapest sources of starch (corn, wheat, and rye) are used in making alcoholic liquids. The operations by which whisky is obtained from grain are technically termed—1. *Mashing*, by which the starch is converted into sugar. 2. *Fermentation*, or the production of the alcohol. 3. *Distillation*, or the separation of the crude spirit.

The crushed grain, mixed with malt, is added to water at 15.56° C. and allowed to stand to permit the conversion of the starch into maltose and dextrose through the action of the diastase. The liquid is now termed the *wort*. This is caused to ferment by the addition of yeast, and alcohol is gradually formed, carbon dioxide escaping. The liquor is then distilled, the distillate being termed *low wines*. This is again distilled, and *raw whisky* is the product. This, upon keeping, especially in a warm room, improves in quality through the formation of esters, which are supposed to communicate an agreeable flavor to the liquid.

Owing to the fact that for many years various blends, mixtures, and dilutions were sold under the generic name whisky, the question of " What is whisky?" has frequently been discussed from the legal standpoint with a view to its commercial interpretation.

The Pharmacopœia has settled the question so far as the medicinal article is concerned by requiring the product to have been aged in charred wood for a period of at least four years. This restricted definition excludes imitation whiskies and diluted whiskies.

In the aging of whisky certain chemical and physical changes occur during which the liquid changes from a colorless alcoholic distillate, having a spirituous odor common to all fresh alcoholic distillates, to a colored liquid having a distinctive odor and certain organoleptic qualities which are associated with genuine whisky and unlike any other alcoholic liquid.

Imitation whiskies consist of diluted alcohol, colored and flavored to resemble the genuine, aged-in-the-wood article. No imitation whisky has ever been produced which cannot be detected by the application of the U. S. P. tests and their intelligent interpretation. The acidity and ester value are of particular importance in this connection as is the test for caramel coloring, which is present in imitation whisky to give it a fictitious appearance of age. The character and amount of the residue upon evaporation are also of importance. A number of the tests in the U. S. P. text are designed to detect and exclude the specially denatured alcohols which recently have found their way into the manufacture of these spurious concoctions which bootleggers usually supply under the name of whisky. Methanol, nicotine, quinine, diethylphthalate, isopropyl alcohol, heavy metals, and other special denaturants have been frequently reported by the analysts examining commercial and official whisky samples.

A more difficult type of deception to detect is that of diluted whisky, in which a certain proportion of genuine whisky is taken and is subsequently

reduced by adding diluted alcohol of whisky proof. If a very old whisky, which possesses a high acidity and high ester value, is taken to start with and the dilution or extension is not very great, this type of fraud is almost impossible to detect with certainty, as the factors would still fall within the limits of the U. S. P. standards and would probably be interpreted as indicating a less mature article, but still of U. S. P. quality. Fortunately, for the analyst, the temptation to make extra profit by dilution is so great that usually it is necessary to add caramel or an aniline dye to imitate age, and this enables the fraud to be detected, for a properly matured whisky needs no caramel or dye to improve its color.

Whisky may be purchased and sold legally only under the regulations of the Volstead Act, as administered by the Internal Revenue Department of the United States Government. The pharmacist has been selected by Congress as one of the most important distributing agents for alcoholic liquors for medicinal use, and his obligation and duty in this professional service must be rendered with a full sense of the grave responsibility involved.

The official description and tests are as follows:

Description and Physical Properties—A light to deep amber-colored liquid, having a characteristic odor and taste, and an acid reaction.

Specific gravity: from 0.935 to 0.923 at 25° C.

Tests for Identity and Purity—The residue obtained by evaporating 20 cc. of Whisky in a dish on a water bath is not completely soluble in 5 cc. of distilled water. Filter the solution and add to the filtrate a drop of diluted ferric chloride T.S. (1 in 10): a greenish-black coloration is produced (*indicating storage in wood barrels*).

A 25 cc. portion of Whisky, diluted with 50 cc. of distilled water, requires for neutralization not less than 1.5 cc. and not more than 5 cc. of tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator.

Mix 100 cc. of Whisky with 15 cc. of distilled water and slowly distil 100 cc., using an efficient condenser. Neutralize 50 cc. of the distillate with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, then add exactly 20 cc. more of the tenth-normal sodium hydroxide and boil for one hour under a reflux condenser. Cool and titrate the excess of alkali with tenth-normal sulphuric acid. Run a blank test, using distilled water in place of the distillate and make any necessary correction. The volume of tenth-normal sodium hydroxide consumed is not less than 1.7 cc. and not more than 7 cc. (*esters*).

To 5 cc. of the distillate add 2 cc. of sodium hydroxide T.S. and 5 drops of a freshly prepared aqueous solution of sodium nitroprusside (1 in 50), then add a slight excess of acetic acid: no violet tint is produced in one minute (*acetone*).

A mixture of 0.5 cc. of the distillate with 5 cc. of distilled water meets the requirements of the test for *methanol* under *Alcohol*.

Acidulate 10 cc. of Whisky with 5 drops of diluted hydrochloric acid and evaporate to 5 cc. Dilute with distilled water to 10 cc. and filter if necessary. The addition of iodine T.S. or mercuric potassium iodide T.S. yields no precipitate (*alkaloids*).

Dilute 10 cc. of Whisky with 2 cc. of distilled water, transfer to a test tube, and shake gently for two minutes with 15 cc. of a mixture of 100 cc. of amyl alcohol, 3 cc. of phosphoric acid, and 3 cc. of distilled water, and allow the layers to separate completely: the lower aqueous layer is colorless or very nearly so (*caramel*).

Mix 5 cc. of Whisky with 5 cc. of distilled water and shake the mixture with 10 cc. of purified petroleum benzin. Transfer the separated benzin to a dish of from 70 to 80 cc. capacity, add 1 cc. of sodium hydroxide solution (1 in 10), and evaporate to dryness on a water bath. Add to the dry residue 2 cc. of sulphuric acid, rotating the acid in the dish so that the residue will be completely moistened. Heat for two minutes on a water bath, and pour the solution into a dry test tube containing from 0.03 to 0.05 Gm. of resorcinol. Heat the mixture for three minutes at 160° to 170° C., shaking at intervals to dissolve all of the resorcinol. Then pour the solution into a mixture of 70 cc. of distilled water and 30 cc. of sodium hydroxide solution (1 in 10), adding more sodium hydroxide, if necessary, to make the mixture alkaline. The liquid shows no yellowish-green fluorescence after standing twenty-four hours (*diethylphthalate*).

Mix 2 cc. of an aqueous solution of phloroglucinol (1 in 100) with 5 cc. of sodium hydroxide T.S. and add 2 cc. of Whisky: no red color is produced (*formaldehyde*).

Mix 20 cc. of Whisky with 20 cc. of distilled water and shake the mixture with 10 cc. of ether. Allow the mixture to stand until separation takes place, separate the ether layer, and allow it to evaporate spontaneously on a watch glass: the residue has no disagreeable or irritating odor.

Evaporate 20 cc. of Whisky in a dish on a water bath and dry the residue to constant weight at 100° C.: the weight of the residue does not exceed 0.10 Gm. This residue is not sticky, it has a slightly astringent taste but is not distinctly sweet or bitter (*glycerin, sugar, etc*).

Evaporate 10 cc. of Whisky to 5 cc. and dilute with 10 cc. of distilled water, acidulate with 5 drops of hydrochloric acid, and add 10 cc. of hydrogen sulphide T.S.: no precipitate is formed before or after rendering alkaline with ammonia T.S. (*heavy metals*).

Place 2 cc. of mercuric sulphate T.S. in a test tube, add 5 drops of Whisky and heat the mixture just to boiling over a small Bunsen burner and remove it from the flame: no yellow precipitate is formed (*isopropyl alcohol*).

The addition of an excess of bromine T.S. to 5 cc. of Whisky, diluted with an equal volume of distilled water, produces no precipitate (*phenols*).

Uses—Crude or "raw" whisky is the chief source of alcohol which is largely used in the industries and arts. When purified and mellowed by age, whisky is used as a stimulant.

SPIRITUS VINI VITIS. U.S. Brandy

[Sp. Vin. Vit.—Spiritus Vini Gallici]

Brandy is an alcoholic liquid obtained by the distillation of the fermented juice of sound, ripe grapes and containing not less than 48 per cent and not more than 54 per cent by volume of C_2H_5OH, at 15.56° C.

It must have been stored in wood containers for a period of not less than four years.

Preparation—Brandy varies in quality according to the source from which it is obtained. The best brandy is obtained from French wines, and the kind called Cognac is most esteemed. Very large quantities of brandy are now made in California but the taste is peculiar and easily distinguished from that of Cognac. The Pharmacopœia recognizes all spirits when obtained from the juice of grapes, if sufficiently strong and pure to meet the tests given below.

Brandy owes its aroma to œnanthic and acetic ethers and other volatile products. Œnanthic ether is known chemically as ethyl pelargonate, $C_{11}H_{22}O_2$, but in commerce it is called *oil of cognac*. It is a fragrant, ethereal oil, of a greenish color.

Brandy resembles whisky in some respects and is totally unlike it in others. The aging is performed in wood containers, but not necessarily in charred wood. Hence brandy is much lighter in color than whisky as a rule, and is permitted to be colored with caramel and even to contain small amounts of sugar. The flavors of whisky and of brandy are distinctly different. The former, being a grain distillate, owes its predominant flavor and odor to *amylic compounds*. Brandy, being a wine distillate, owes its characteristic aroma and flavor to certain esters never found in whisky, of which *ethyl pelargonate* is an example.

The detection of spurious or of diluted brandy is much more difficult than in the case of whisky, unless foreign substances included in the list of special denaturants are found to be present.

Description and Physical Properties—A pale amber-colored liquid, having a characteristic odor and taste, and an acid reaction.

Specific gravity: from 0.933 to 0.921 at 25° C.

Tests for Identity and Purity—Evaporate 20 cc. of Brandy in a dish on a water bath, treat the residue with 5 cc. of distilled water, filter, and add to the filtrate a drop of diluted ferric chloride T.S. (1 in 10): a greenish-black coloration is produced (*indicating storage in wood barrels*).

Evaporate 20 cc. of Brandy in a dish on a water bath and dry the residue to constant weight at 100° C.: the weight of the residue does not exceed 0.30 Gm.

A 25 cc. portion of Brandy, diluted with 50 cc. of distilled water, requires for neutralization not more than 3.8 cc. of tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator (*free acid*).

Dilute 20 cc. of Brandy with 5 cc. of distilled water and slowly distil 20 cc., using an efficient condenser: the distillate meets the requirements of the tests for *acetone* and *methanol* under *Spiritus Frumenti*.

Brandy meets the requirements of the tests for purity under *Spiritus Frumenti*, beginning with the test for *alkaloids* but omitting the tests for *caramel* and for *glycerin, sugar, etc.*

Uses—Brandy is employed as a stimulant, and is often administered with milk, yolk of eggs, etc.

ÆTHER. U.S. **Ether**, STRONGER ETHER, PHARM. 1880, "SULPHURIC ETHER"

Ether contains from 96 per cent to 98 per cent of $(C_2H_5)_2O$, the remainder consisting of alcohol and water.

Caution—Ether to be used for anesthesia must be preserved only in small, well-closed containers, and is not to be used for this purpose, if the original container has been opened longer than twenty-four hours.

Preparation—Ether is made by acting on alcohol with sulphuric acid between the temperatures of 130° and 137.7° C., which is known as the etherifying temperature. The sulphuric acid is not consumed in the process, but is regenerated, so that the making of ether is practically continuous. This will be understood when the reactions are explained. Ether is the oxide of the monad radicle ethyl, C_2H_5. Alcohol, as has been already stated, is the hydroxide, C_2H_5OH.

The following equation illustrates the production of ether:

$$\underset{\text{alcohol}}{C_2H_5OH} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{H_2SO_4} = \underset{\substack{\text{ethylsulphuric}\\\text{acid}}}{C_2H_5HSO_4} + \underset{\text{water}}{H_2O}$$

then

$$\underset{\substack{\text{ethylsulphuric}\\\text{acid}}}{C_2H_5HSO_4} + \underset{\text{alcohol}}{C_2H_5OH} = \underset{\text{ether}}{(C_2H_5)_2O} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{H_2SO_4}$$

Formerly it was believed that the sulphuric acid acted as a catalyzer and that it dehydrated the alcohol through its affinity for water; but the presence of ethylsulphuric acid, which is formed during the process, has made it necessary to abandon this simple theory.

Ether is now made from tax-free, specially denatured alcohol, and is consequently greatly reduced in price and may be used economically in the preparation of the oleoresins where it has again replaced acetone in the U. S. P.

Description and Physical Properties—A transparent, colorless, mobile liquid, having a characteristic odor, and a burning, sweetish taste. It is highly volatile and inflammable. Its vapor when mixed with air and ignited may explode violently. It is slowly oxidized by the action of air, moisture, and daylight with the formation of peroxides.

Ether is soluble in about 12 times its volume of water at 25° C. with slight contraction of volume. It is miscible with alcohol, benzene, chloroform, petroleum benzin, and fixed or volatile oils.

Tests for Identity—Specific gravity: 0.713 to 0.716 at 25° C.

Boiling point: about 35° C.

Tests for Purity—The color of light blue litmus paper moistened with water is not changed to red when the paper is immersed in Ether for ten minutes.

Allow 50 cc. of Ether to evaporate spontaneously from a shallow dish, and dry at 100° C. for one hour: the residue does not exceed 0.001 Gm.

Place 10 cc. of 80 per cent alcohol in a 50 cc. glass-stoppered flask, add 0.5 cc. of phenolphthalein T.S. and just sufficient fiftieth-normal sodium hydroxide to produce a pink color which persists after shaking for one-half minute. Then add 25 cc. of Ether, stopper the flask, mix gently, and add again fiftieth-normal sodium hydroxide until the pink color persists after shaking for one-half minute: not more than 0.4 cc. additional fiftieth-normal sodium hydroxide is required to neutralize the Ether (*acid*).

Pour 10 cc. of Ether, in portions, upon clean, odorless blotting paper, and allow it to evaporate spontaneously: no foreign odor is perceptible when the last traces of Ether evaporate from the paper.

Shake 10 cc. of Ether occasionally during two hours with 1 cc. of potassium hydroxide T.S. in a glass-stoppered container, protected from light: no color is developed in either liquid (*aldehyde*).

Shake 10 cc. of Ether occasionally during one hour with 1 cc. of a freshly made solution of cadmium and potassium iodide (1 in 10), in a glass-stoppered cylinder, previously rinsed with the Ether under examination and protected from light: no color develops in either liquid (*peroxide*).

Preserve in partially filled, well-closed, light-proof containers, in a cool place, remote from fire.

History—Valerius Cordus in 1517 described ether or a very similar product under the name *Oleum Vitriolo Dulce*. Later it was called *Spiritus Vini Aethereius*, and still later *Ether Sulphuricus*.

In 1842 Dr. Crawford Long of Athens, Georgia, first used ether as a general anesthetic. In 1844 Dr. Horace Wells, of Hartford, Conn., used it independ-

ently for the same purpose and Doctor Jackson of Boston, Mass., had used it several years earlier. The first hospital operation under ether anesthesia was performed in Boston, in 1846.

Uses—Ether is used principally as an anesthetic, and, notwithstanding the many efforts made to supplant it, continues to be the most largely used substance employed for producing insensibility to pain in surgical operations. It is occasionally given by mouth as a carminative. It is also used as a solvent. It dissolves iodine and bromine freely, and sulphur and phosphorus sparingly. Its power to dissolve corrosive sublimate makes it a useful agent in the manipulations for detecting that poison. It is also a solvent of volatile and fixed oils, many resins and balsams, tannic acid, caoutchouc, and most of the alkaloids.

Especial care should be observed in pouring ether from one vessel to another in the presence of a flame, as the vapor is heavy—two and a half times as heavy as air—and it readily ignites with explosive violence, when mixed with air.

OLEUM ÆTHEREUM N. F. Ethereal Oil

[Ol. Æther.]

A volatile liquid consisting of equal volumes of heavy oil of wine and ether.

	Metric	Alternative
Alcohol	**1000 cc.**	2 pints
Sulphuric Acid	**1000 cc.**	2 pints
Distilled Water	**25 cc.**	384 min.
Ether, a sufficient quantity.		

Add the sulphuric acid slowly to the alcohol, mix them thoroughly, and allow the mixture to stand, in a closed flask, for twenty-four hours, or until the liquid is clear; then pour the clear liquid into a tubulated retort of such capacity that the mixture shall nearly fill it. Insert a thermometer through the tubulure, so that the bulb shall be deeply immersed in the liquid, and having connected the retort with a well-cooled condenser, and also having connected a bent glass tube with the receiver for conducting the uncondensed gases into water, distil, by means of a sand bath, at a temperature between 150° and 160° C. until oily drops cease to come over, or until a black froth, which forms on the surface, begins to rise in the retort. Separate the yellow, ethereal liquid from the distillate, and expose it to the air for twenty-four hours, in a shallow dish. Then transfer it to a wet filter, and, when the aqueous portion has drained off, wash the oil which is left on the filter with the distilled water, which must be as cold as possible. When this also has drained off, transfer the oil to a graduated measure and add to it an equal volume of ether.

Preserve the product in small, glass-stoppered bottles, in a cool place.

A transparent, nearly colorless, volatile liquid of a peculiar, aromatic, ethereal odor, and a pungent, refreshing, bitter taste; neutral to dry litmus paper.

Specific gravity: about 0.905 at 25° C.

N. F. Preparation—Spiritus Etheris Compositus.

If alcohol is distilled with a large excess of sulphuric acid, there are formed toward the close of the distillation heavy oil of wine, sulphurous acid, olefiant gas, and empyreumatic products. The product of the distillation is generally in two layers, one consisting of water holding sulphurous acid in solution, and the other, of ether containing the heavy oil of wine. After separation, the latter liquid is exposed for twenty-four hours to the air, in order to dissipate the ether by evaporation, and the oil which is left is washed with water to deprive it of all traces of sulphurous acid.

In the early stage of the distillation of a mixture of sulphuric acid and alcohol, ethylsulphuric acid, $C_2H_5HSO_4$, is formed. During its progress, this is decomposed so as to yield ether. When, however, the alcohol is distilled with a large excess of sulphuric acid, the ethylsulphuric acid is decomposed so as to form a small quantity of the heavy oil of wine. This is a mixture of ethyl sulphate, $(C_2H_5)_2SO_4$, ethyl sulphite, $(C_2H_5)_2SO_3$ (the sulphurous acid having been formed by reduction of sulphuric acid), with polymeric forms of ethylene, C_2H_4.

Uses—Ethereal oil is used solely as an ingredient in compound spirit of ether. It differs from the official liquid in containing variable proportions of light and heavy oil of wine, ether, and alcohol. It is obtained as a by-product in the manufacture of ether.

During the rectification of crude ether, the distillation is continued as long as ether of the proper specific gravity comes over; after which the receiver is changed and an additional distillate is obtained, consisting of ether and alcohol impregnated with a little ethereal oil. It is this second distillate, variously modified by the addition of alcohol, ether, or water, so as to make it conform in taste, smell, opalescence, etc., to a standard preparation kept by the manufacturer, that is sold as Hoffmann's anodyne.

The expensiveness of the ethereal oil is alleged to be the cause of this substitution. The cheap commercial liquid may be known by adding it to water; it usually mixes without causing milkiness. The official compound spirit of ether produces a slight opalescence when forty drops are added to a pint of water, and the peculiar odor or ethereal oil is distinctly noticed; but castor oil is sometimes added by dishonest manufacturers to circumvent this test. This fraud may be detected by mixing equal parts of the suspected liquid and water, and collecting the oil which separates on a piece of filtering paper and exposing it to heat. A permanent greasy stain indicates a fixed oil, while an ethereal oil stain disappears on heating.

SPIRITUS ÆTHYLIS NITRITIS. U. S. Spirit of Ethyl Nitrite

[**Sp. Æth. Nitrit.**—Spiritus Ætheris Nitrosi U. S. P. IX, Spirit of Nitrous Ether, Sweet Spirit of Nitre]

Spirit of Ethyl Nitrite is an alcoholic solution of ethyl nitrite containing not less than 3.5 per cent and not more than 4.5 per cent of $C_2H_5NO_2$ (75.06).

The several manufacturing processes will be found on pages 305 to 307. In these, ethyl nitrite, an ester, is produced by substituting the acid radicle for the hydroxyl in the alcohol. This is then preserved from decomposition by the addition of sufficient alcohol.

Unofficial manufacturing processes are outlined on page 306. The distillation method is the only one applicable to large-scale preparation, but the U. S. P. IX process may be used in emergency by the practicing pharmacist, since it may be completed with the usual apparatus in the drug store laboratory.

The following equation is illustrative of the chemistry of either process:

$$\underset{\text{alcohol}}{2C_2H_5.OH} + \underset{\text{sodium nitrite}}{2NaNO_2} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{ethyl nitrite}}{2C_2H_5NO_2} + \underset{\text{sodium sulphate}}{Na_2SO_4} + \underset{\text{water}}{2H_2O}$$

Pure ethyl nitrite is pale yellow, has the odor of apples, boils at 18° C. (note that this is below the body temperature), and has the specific gravity 0.900 at 15.56° C. The density of its vapor is 2.627. Litmus is not affected by it. It is soluble in forty-eight parts of water, and in all proportions in alcohol. It is highly inflammable and burns with a white flame without residue. Mixed with an alcoholic solution of potassium hydroxide, it becomes dark brown, showing the presence of aldehyde. When kept, the pure ethyl nitrite and also the Spirit become acid in a short time, as shown by litmus, and nitric oxide is given off, which often causes the bottle to burst. The tendency to become acid is rendered greater by the action of the air, and depends on the absorption of oxygen by the aldehyde which is converted into acetic acid. These facts show the necessity of preserving the spirit in *small, well-stoppered, dark amber-colored bottles, in a cool and dark place, remote from fires,* as required by the Pharmacopœia *and, in warm weather, of cooling the stock bottle thoroughly before opening it. The pharmacist should abandon the custom of keeping the solution in the regular glass-stoppered shop bottle, partially filled and exposed to heat and light.* This need not be a hardship, however, as the spirit may be placed in suitable small bottles, as soon as prepared, and be ready for dispensing or sale without further handling.

Spirit of ethyl nitrite is now usually prepared by mixing pure ethyl nitrite directly with the specified volume of alcohol, the ethyl nitrite being obtainable

in hermetically sealed tubes holding just sufficient ethyl nitrite for one pint of the official spirit. The tube should be well cooled, and the narrow neck plunged beneath the alcohol, before opening. It is well to wrap the tube in a towel before carrying out this operation, as the tubes have been known to explode violently, especially if the ethyl nitrite has not been recently prepared. The tubes are usually dated and the pharmacist cautioned not to use old stock.

The U. S. P. describes spirit of ethyl nitrite as follows:

Description and Physical Properties—A clear, mobile liquid of a pale yellow or faintly greenish-yellow tint. It has a fragrant, ethereal, pungent odor, free from acridity, and a sharp, burning taste. It is volatile and inflammable and rapidly decomposes on exposure to light and air.

When freshly prepared or even after being kept for some time with but little exposure to light and air, it is neutral to dry litmus paper. When long kept or after having been exposed to light and air, it acquires an acid reaction.

Specific gravity: not above 0.823 at 25° C.

Tests for Identity and Purity—Immerse a test tube half filled with the Spirit in a water bath heated to 65° C. until it has acquired that temperature: the Spirit distinctly boils upon the addition of a few small pieces of broken glass.

Effervescence does not result when a crystal of potassium bicarbonate is added to 5 cc. of the Spirit (*free acid*).

Mix 10 cc. of the Spirit with 5 cc. of potassium hydroxide T.S. previously diluted with 5 cc. of distilled water: the mixture assumes a yellow color which does not turn decidedly brown within twelve hours (*aldehyde*).

Assay—Transfer about 40 cc. of Spirit of Ethyl Nitrite, which has been previously shaken with 0.5 Gm. of powdered potassium bicarbonate, to a tared, 100 cc. measuring-flask, and weigh accurately. Add sufficient alcohol to bring the volume to exactly 100 cc. and mix thoroughly. Introduce into a nitrometer, page 1517, exactly 10 cc. of the alcoholic solution, followed by 10 cc. of potassium iodide T.S. and afterwards by 5 cc. of diluted sulphuric acid. When the volume of gas has become constant (within thirty to sixty minutes), note the volume of gas collected. Multiply this volume in cc. by 0.307, and divide the product by one-tenth of the weight of the Spirit of Ethyl Nitrite taken. At standard temperature and pressure, the quotient represents the percentage of ethyl nitrite in the liquid. The temperature correction is 1/273 of the total percentage just found for each degree of temperature, added if the temperature is below, subtracted if above, 25° C. The barometric correction is 1/760 of the total percentage just found for each mm., added if above, subtracted if below, 760 mm.

This assay is explained on page 1482.

Preserve in small, well-stoppered, dark amber-colored bottles, in a cool, dark place, remote from fire.

Alcohol content, by volume, 85 to 93 per cent.

Uses—Spirit of ethyl nitrite is a valuable diaphoretic and diuretic. The dose is thirty minims to one fluidrachm (2 to 4 cc.).

ÆTHYLIS CHLORIDUM. U. S. Ethyl Chloride

[Æthyl. Chlor.]

Monochlorethane [C_2H_5Cl = 64.51].

Preparation—Ethyl chloride may be made by the action of dry hydrochloric acid gas upon alcohol. The yield by this method is low unless zinc chloride is added to the alcohol before passing in the hydrogen chloride. The equation is as follows:

$$\underset{\text{ethyl alcohol}}{C_2H_5OH} + \underset{\substack{\text{hydrogen}\\\text{chloride}}}{HCl} = \underset{\substack{\text{ethyl}\\\text{chloride}}}{C_2H_5Cl} + \underset{\text{water}}{H_2O}$$

Ethyl chloride is more conveniently prepared by distilling a mixture of alcohol, sodium chloride, and sulphuric acid according to the following equation:

$$\underset{\text{ethyl alcohol}}{C_2H_5OH} + \underset{\substack{\text{sodium}\\\text{chloride}}}{NaCl} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{H_2SO_4} = \underset{\text{ethyl chloride}}{C_2H_5Cl} + \underset{\substack{\text{acid sodium}\\\text{sulphate}}}{NaHSO_4} + \underset{\text{water}}{H_2O}$$

The vapor is finally condensed with the aid of ice surrounding the receiver.

Description and Physical Properties—At low temperatures or under pressure it is a colorless, mobile, very volatile liquid. It has a characteristic, ethereal odor, and a burning taste.

When Ethyl Chloride is liberated at ordinary room temperature from its sealed container, it vaporizes at once. *As its vapor is very inflammable, do not use it near fire.* It burns with a smoky, greenish flame with the production of hydrogen chloride.

Ethyl Chloride is slightly soluble in water, and is freely soluble in alcohol and in ether.

Tests for Identity—Specific gravity: about 0.921 at 0° C.

Boiling point: between 12° and 13° C.

Tests for Purity—Add a few drops of silver nitrate T.S. to 10 cc. of alcohol, cool to the temperature of melting ice, and add to the clear liquid about 0.5 cc. of Ethyl Chloride cooled in the same manner: no turbidity is produced at once (*chloride*).

Shake 10 cc. of Ethyl Chloride with 10 cc. of distilled water, both previously cooled to the temperature of melting ice, and allow the supernatant stratum of Ethyl Chloride to evaporate spontaneously: the residual liquid is neutral to litmus paper, and on adding to it a few drops of potassium dichromate T.S., followed by 2 cc. of diluted sulphuric acid, and boiling the mixture, no odor of aldehyde is developed, and no greenish or purplish color is produced (*alcohol*).

Allow 5 cc. of Ethyl Chloride to evaporate spontaneously from a shallow dish: no foreign odor is noticeable while the last portions evaporate, and only a negligible residue remains.

Preserve in hermetically sealed containers, in a cool place, remote from fire, protected from light.

Uses—Ethyl chloride is used as a local anesthetic by "freezing"; its great volatility requires special methods for dispensing; hermetically sealed tubes are used, so made that when the end is broken off, or the metallic orifice opened, and the tube held in the hand, the heat causes expansion and expells the liquid in a fine stream which is directed against the part to be anesthetized. It is also employed as a general anesthetic by inhalation, especially for minor operations.

ÆTHYLIS CHAULMOOGRAS. U. S. Ethyl Chaulmoograte

[Æthyl. Chaulmoog.]

The ethyl esters of the fatty acids of chaulmoogra oil.

Description and Physical Properties—A clear, pale yellow liquid, having a slight, fruity odor. It is insoluble in water, but is miscible with alcohol, chloroform, and ether.

Tests for Identity and Purity—Specific gravity: about 0.904 at 25° C.

The specific rotation $[\alpha]_D$ of Ethyl Chaulmoograte, determined at 25° C. in chloroform, containing in each 10 cc. of solution 5 cc. of the Ethyl Chaulmoograte, and using a 100 mm. tube, is not less than +44.5°, page 1524.

A solution of 1 cc. Ethyl Chaulmoograte in 10 cc. of neutralized alcohol requires not more than 0.1 cc. of tenth-normal sodium hydroxide for neutralization, using 2 drops of phenolphthalein T.S. as indicator (*free acid*).

Saponification value: not less than 190 and not more than 196, page 1519.

Iodine value: not less than 90 and not more than 100, page 1519.

Preserve in well-closed containers.

Uses—The uses are described under chaulmoogra oil, page 1035. It is administered in gradually increasing doses of from 1 cc. to 5 cc. daily after meals with warm milk or hot tea. Intramuscularly, 1 cc. is the initial dose, this being increased by 1 cc. every second or third injection until a maximum of 3 cc. to 5 cc. is reached. The injections are administered once a week. The only preparation of Ethyl Chaulmoograte on the American market is sold by the Bayer Company, Inc., under the trademarked name "*Chaulmestrol*". The patent on this expires in 1927.

SULPHONMETHANUM. U. S. Sulphonmethane

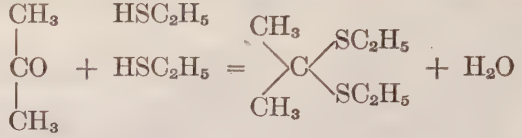
[Sulphonmeth.—Sulphonal]

Diethylsulphon-dimethylmethane $[(CH_3)_2C(SO_2C_2H_5)_2 = 228.28]$.

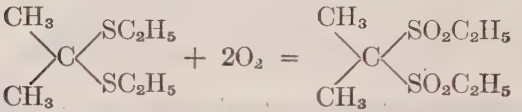
Preparation—Sulphonmethane or *Sulphonal* may be made by agitating mercaptol, obtained by the condensation of acetone with ethyl mercaptan, with a 5 per cent solution of potassium permanganate until the color of the solution remains unchanged, thus showing that the oxidation is completed.

The crystals are purified by redissolving in water or alcohol, and evaporating the solution, collecting, and drying the product.

The synthesis of this product is described by the following equations:



acetone ethyl mercaptan acetone-ethyl mercaptol water



acetone-ethyl mercaptol oxygen sulphonal

Description and Physical Properties—Colorless, odorless crystals or a white, odorless powder.

One Gm. of Sulphonmethane is soluble in 365 cc. of water, 60 cc. of alcohol, 11 cc. of chloroform, and in 64 cc. of ether, at 25° C. One Gm. is soluble in 16 cc. of boiling water and in 3 cc. of boiling alcohol. It is soluble in benzene.

Tests for Identity and Purity—Sulphonmethane melts between 124° and 126° C.

In other respects it responds to the tests for identity and purity under *Sulphonethylmethanum*.

Preserve in well-closed containers.

Uses—Sulphonmethane is not readily soluble, is slowly absorbed, and its hypnotic action is but slowly established. It is used as a hypnotic in doses of twelve to fifteen grains (0.75 to 1 Gm.). It should be administered in a hot liquid. When sulphonmethane or sulphonethylmethane are used frequently, the administration should be suspended once in two or three days to permit complete elimination.

SULPHONETHYLMETHANUM. U.S. Sulphonethylmethane

[Sulphonethylmeth.—TRIONAL]

Diethylsulphon-methylethylmethane $[(CH_3)(C_2H_5)C(SO_2C_2H_5)_2]$.

Preparation—Sulphonethylmethane or *Trional* is made by the same process as that employed in making sulphonal (see above), except that in making the mercaptol, acetone is replaced by methylethylketone, thus substituting an ethyl for a methyl group.

Description and Physical Properties—Colorless, lustrous, odorless, crystalline scales, having a bitter taste in aqueous solution.

One Gm. of Sulphonethylmethane is soluble in 200 cc. of water at 25° C. It is more soluble in boiling water; soluble in alcohol and in ether.

Tests for Identity—A saturated aqueous solution of Sulphonethylmethane is neutral to litmus paper.

It melts between 74° and 76° C.

When strongly heated, it is decomposed, with the evolution of sulphur dioxide.

Heat about 0.1 Gm. of Sulphonethylmethane with an equal weight of powdered charcoal in a dry test tube: the characteristic unpleasant odor of mercaptan is evolved.

Tests for Purity—Ash: not more than 0.05 per cent.

Boil 2 Gm. of Sulphonethylmethane with 100 cc. of distilled water until solution is complete: no odor develops. Cool the solution, add sufficient distilled water to restore the volume to 100 cc., filter, and to 20 cc. of the filtrate add 0.05 cc. of tenth-normal potassium permanganate: the pink color does not disappear at once (*readily oxidizable substances*).

To 10 cc. of the filtrate obtained in the preceding test add a few drops of silver nitrate T.S.: no turbidity is produced at once (*chloride*).

A 50 cc. portion of the same filtrate shows no more *sulphate* than corresponds to 1 cc. of fiftieth-normal sulphuric acid, page 1520.

Preserve in well-closed containers.

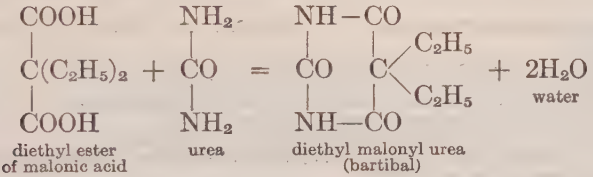
Uses—Sulphonethylmethane or Trional is used as a hypnotic in doses of twelve to fifteen grains (0.75 to 1 Gm.). It is more soluble than sulphonmethane and acts more quickly. It should be administered in a hot liquid. It is usually effective within an hour or two.

BARBITALUM. U.S. Barbital

[**Barbital.**—Diethylbarbituric Acid, Barbitone, Veronal]

Diethylmalonylurea $[CO(HN.CO)_2C(C_2H_5)_2]$.

Preparation—Barbital is made by the interaction of the diethyl ester of malonic acid and carbamide. The reaction is illustrated as follows:



Description and Physical Properties—Colorless or white, crystals, or a white crystalline powder. It is odorless, has a slightly bitter taste, and is stable in the air.

One Gm. of Barbital is soluble in 130 cc. of water, 14 cc. of alcohol, 75 cc. of chloroform, and in 35 cc. of ether, at 25° C. One Gm. is soluble in 13 cc. of boiling water. It is also soluble in acetone and in ethyl acetate.

Tests for Identity—Barbital melts between 187° and 190° C.

A saturated aqueous solution of Barbital is acid to litmus paper.

A saturated aqueous solution of Barbital yields with mercuric nitrate T.S. a white precipitate which is soluble in an excess of the reagent.

When Barbital is boiled with an excess of sodium carbonate T.S. for thirty minutes, or when fused with sodium hydroxide, it is decomposed with the evolution of ammonia.

Tests for Purity—The ash from 0.5 Gm. is negligible.

A solution of 0.2 Gm. of Barbital in 2 cc. of sulphuric acid is colorless (*readily carbonizable substances*). Another portion of 0.2 Gm. of Barbital is not colored by shaking with 2 cc. of nitric acid.

Uses—Barbital is quickly absorbed, especially when it is given in solution. In small doses it induces sleep, apparently without any other effect. In larger doses the temperature falls and animals show marked trembling and restlessness in their sleep. In small doses it is a relatively safe hypnotic, but fatalities have followed its indiscriminate use.

It is claimed that barbital is useful in simple insomnia, as well as in accompanying hysteria, neurasthenia and mental disturbances. The formation of a habit has been reported.

Dose—From 5 to 15 grains (0.3 to 1 Gm.), in hot water, tea or milk, or, if in wafers or capsules, followed by a cupful of some warm liquid.

The title *veronal* is trademarked by the Winthrop Chemical Company, Inc.

Barbital Compounds

Prolonged heating with sodium carbonate solution liberates ammonia. Deniges' reagent (mercuric sulphate) produces a white precipitate; in a solution acidulated with nitric acid, Millon's reagent produces a precipitate.

Barbital-Abbott—A brand of barbital-N. N. R.
Manufactured by The Abbott Laboratories, Chicago, under U. S. patent 782,739 (Feb. 14, 1905; expired).
Barbital-Abbott Tablets, 5 grains.

Barbital-M. C. W.—A brand of barbital-N. N. R.
Mallinckrodt Chemical Works, St. Louis, distributor. No U. S. patent or trademark.

Barbital-Merck—A brand of barbital-N. N. R.
Merck and Company, New York, distributor. No U. S. patent or trademark.

Veronal—A brand of barbital-N. N. R.
Manufactured by Winthrop Chemical Company, Inc., New York. U. S. patent 782,739 (Feb. 14, 1905; expired). U. S. trademark 40,115.
Veronal Tablets, 5 grains.
Elixir of Veronal—Each fluidrachm contains veronal 2 grains in a menstruum containing alcohol 33.5 per cent.

BARBITALUM SOLUBILE. U.S. Soluble Barbital

[**Barbital. Sol.**—Barbital Sodium, Sodium Diethylbarbiturate, Sodium Diethylmalonylurea, Barbitone Sodium, Veronal-Sodium]

Soluble Barbital, when dried to constant weight at 100° C., contains not less than 98.5 per cent of $CO(NaN.CO)(HN.CO)C(C_2H_5)_2$.

A sodium salt of Barbital, , which is more soluble in water and with a more bitter, alkaline taste. It differs structurally from barbital only in having one atom of hydrogen replaced by an atom of sodium.

Description and Physical Properties—A white powder. It is odorless, has a bitter taste, and is stable in the air.

One Gm. of Soluble Barbital is soluble in about 5 cc. of water at 25° C., and in 2.5 cc. of boiling water. It is slightly soluble in alcohol and is insoluble in ether.

Tests for Identity—The barbital obtained in the assay melts between 187° and 190° C., and responds to the other identity tests given under *Barbitalum*.

An aqueous solution of Soluble Barbital is alkaline to litmus paper.

The addition of diluted hydrochloric or sulphuric acid to an aqueous solution of the salt (1 in 20) produces a precipitate of barbital.

Tests for Purity—A solution of 0.2 Gm. of the salt in 2 cc. of sulphuric acid is colorless (*readily carbonizable substances*).

Ten cc. portions of an aqueous solution of Soluble Barbital (1 in 100) acidulated with a few drops of nitric acid yield no opalescence at once on the addition of a few drops of silver nitrate T.S. (*chloride*), and no turbidity within one minute on the addition of 1 cc. of barium chloride T.S. (*sulphate*).

An aqueous solution of the salt meets the requirements of the test for *heavy metals*, page 1519.

When dried to constant weight at 100° C., it loses not more than 1 per cent (*water*).

Shake 0.5 Gm. of Soluble Barbital with 20 cc. of dehydrated ether for ten minutes, filter, evaporate the ether, and dry at 100° C.: the weight of the residue does not exceed 0.003 Gm. (*uncombined barbital*).

Assay—Dissolve about 1 Gm. of Soluble Barbital, previously dried at 100° C. and accurately weighed, in 10 cc. of distilled water in a separator, add to the solution 15 cc. of diluted hydrochloric acid, and extract the liberated barbital by shaking successively with eight portions of 25 cc. each of ether. Evaporate the combined ether solutions at as low a temperature as possible, and dry at 100° C. The weight of the barbital so obtained is not less than 88 per cent and not more than 90 per cent of the dried Soluble Barbital. About 0.2 Gm. of the Barbital, obtained in the assay, leaves a negligible residue upon ignition.

This assay is explained on page 1476.

Uses—The same as those of barbital, but it is claimed that this drug acts more rapidly on account of its greater solubility. Because of its solubility, administration by rectal injection and also subcutaneous injection has been proposed.

The title *veronal-sodium* is trademarked by the Winthrop Chemical Company, Inc.

Dose—The same as that of barbital. It should be administered in an aqueous solution.

Barbital Sodium-Abbott—A brand of barbital sodium-N. N. R.
Manufactured by The Abbott Laboratories.
Elixir Barbital Sodium-Abbott—Each fluidounce contains barbital sodium-Abbott 20 grains in a liquid composed of water and glycerin, and sugar flavored.
Barbital Sodium-Merck—A brand of barbital sodium-N. N. R.
Merck and Company, distributor.
Veronal-Sodium—A brand of barbital sodium-N. N. R.
Manufactured by Winthrop Chemical Company, Inc., New York.
Veronal-Sodium Tablets, 5 grains.

CARBROMALUM. U.S. Carbromal

[**Carbrom.**—Bromdiethylacetylurea, Adalin]

Brom-diethylacetyl carbamide $[C(C_2H_5)_2Br.CONH.CONH_2]$.

Description and Physical Properties—A white, crystalline, odorless powder.

One Gm. of Carbromal is soluble in about 3000 cc. of water, 18 cc. of alcohol, 3 cc. of chloroform, and in 14 cc. of ether, at 25° C. It is very soluble in boiling alcohol. It dissolves in sulphuric,

nitric, and in concentrated hydrochloric acids, from which it is precipitated by dilution with water. It is dissolved by solutions of alkali hydroxides.

Tests for Identity—Carbromal melts between 116° and 117° C.

On boiling about 0.2 Gm. of Carbromal with 5 cc. of a 10 per cent aqueous sodium hydroxide solution: ammonia is evolved.

Mix 0.1 Gm. of Carbromal with 0.5 Gm. of anhydrous sodium carbonate, and ignite gently until completely decomposed. Dissolve the residue in 5 cc. of hot distilled water, cool, acidulate with acetic acid, and filter. Add to the filtrate 2 cc. of chloroform and then chlorine T.S., drop by drop: the chloroform acquires a red-brown color on shaking.

Tests for Purity—The ash from 0.5 Gm. is negligible.

A solution of 0.2 Gm. of Carbromal in 2 cc. of sulphuric acid is colorless or at most faintly brown (*readily carbonizable substances*).

Shake 1 Gm. of Carbromal with 20 cc. of distilled water during five minutes, and filter; the filtrate is neutral to litmus paper.

Five cc. portions of the filtrate obtained in the preceding test show no more *chloride* than corresponds to 0.1 cc. of fiftieth-normal hydrochloric acid, and no more *sulphate* than corresponds to 0.1 cc. of fiftieth-normal sulphuric acid, page 1520.

Uses—Carbromal is said to be an efficient and prompt sedative, reducing excitement and promoting sleep in conditions in which a powerful hypnotic is not required. In therapeutic doses it is said not to exert any unfavorable influence on the respiration or heart action. The sleep produced is said to be restful, dreamless and exceptionally free from unpleasant by-effects and sequelæ.

Carbromal is stated to be useful as a sedative and mild hypnotic in neurasthenia, hysteria, cardiac neuroses with tachycardia, chorea, mental disorders with moderate excitement, insomnia due to various internal diseases, etc.

The title *adalin* is trademarked by the Winthrop Chemical Company, Inc.

Dose—As a sedative from 5 to 10 grains (0.3 to 0.6 Gm.) given in cold water, repeated three or four times daily if necessary; as a hypnotic from 10 to 20 grains (0.6 to 1.3 Gm.), followed by a drink of hot, sweetened water or weak tea.

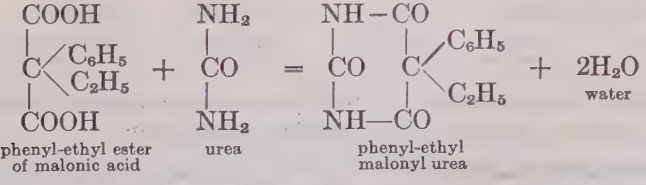
Manufactured by Bayer Company, and distributed by the Winthrop Chemical Company, Inc.

PHENOBARBITALUM. U.S. Phenobarbital

[**Phenobarb.**—PHENYLETHYLMALONYLUREA, LUMINAL]

Phenylethyl Barbituric acid $[CO(NH.CO)_2C(C_2H_5)(C_6H_5)]$.

Preparation—Luminal is closely related chemically to barbital in that it represents barbital with an ethyl group replaced by a phenyl group. The equation showing its production is given as follows:



Description and Physical Properties—White, glistening, small crystals, or a white, crystalline powder. It is odorless, and is stable in the air.

One Gm. of Phenobarbital is soluble in about 1000 cc. of water, 8 cc. of alcohol, 40 cc. of chloroform, 13 cc. of ether, and in about 700 cc. of benzene, at 25° C. It is soluble in solutions of alkali hydroxides and of alkali carbonates.

Tests for Identity—Phenobarbital melts between 172° and 174° C.

A saturated aqueous solution of Phenobarbital is acid to litmus paper.

Boil about 0.2 Gm. of Phenobarbital with 5 cc. of a 25 per cent sodium hydroxide solution: ammonia is evolved.

Shake about 0.3 Gm. of Phenobarbital for two minutes with 1 cc. of normal sodium hydroxide and 5 cc. of distilled water, filter, and divide the filtrate into 2 portions. To 1 portion add mer-

curic chloride T.S.: a white precipitate is produced. To the other portion add silver nitrate T.S., a few drops at a time: a white precipitate is produced which at first redissolves but becomes insoluble when an excess of silver nitrate has been added.

Tests for Purity—The ash from 0.5 Gm. is negligible.

A solution of 0.2 Gm. of Phenobarbital in 2 cc. of sulphuric acid is colorless or only faintly yellow (*readily carbonizable substances*).

Boil 2 Gm. of Phenobarbital with 10 cc. of alcohol under a reflux condenser during three minutes: a clear and complete solution results (*phenylbarbituric acid*).

Uses—It is claimed that the introduction of the phenyl group increases the hypnotic power of phenobarbital over that of barbital but the relative toxicity of hypnotic doses of luminal and barbital has not been determined definitely.

A period of excitement sometimes precedes sleep.

Luminal is used as a useful hypnotic in nervous insomnia and conditions of excitement of the nervous system; its chief use in this field is as a sedative and antispasmodic in the treatment of epilepsy. Its use as a sedative has also been proposed in chorea, neurasthenia, cardiac and gastric neuroses, climacteric disorders, dysmenorrhea, exophthalmic goiter, and pre- and post-operative cases, but it should be remembered that it has no curative action, in such conditions.

The title *luminal* is trademarked by the Winthrop Chemical Company, Inc.

Dose—From ½ to 5 grains (0.03 to 0.3 Gm.), increased if necessary to 12 grains (0.8 Gm.). A maximum dose of 12 grains (0.8 Gm.) should not be exceeded.

A soluble sodium salt of phenobarbital is also sold under the title *phenobarbital sodium* or *luminal-soluble*. The uses are the same as for phenobarbital with a 10 per cent increase in dose.

AMYLIS NITRIS. U.S. Amyl Nitrite

[Amyl. Nitris]

Amyl Nitrite contains not less than 80 per cent of $C_5H_{11}NO_2$ (117.12).

Preparation—Amyl Nitrite is conveniently prepared by distilling a mixture of amyl alcohol, sodium nitrite, and sulphuric acid, as indicated by the following equation:

$$\underset{\text{amyl alcohol}}{C_5H_{11}OH} + \underset{\substack{\text{sodium}\\\text{nitrite}}}{NaNO_2} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{H_2SO_4} = \underset{\text{amyl nitrite}}{C_5H_{11}NO_2} + \underset{\substack{\text{acid sodium}\\\text{sulphate}}}{NaHSO_4} + \underset{\text{water}}{H_2O}$$

Difficulties are experienced in rectifying amyl nitrite on account of the number of products present having similar boiling points.

Description and Physical Properties—A clear, yellowish liquid, having a peculiar, ethereal, fruity odor, and a pungent, aromatic taste. It is volatile even at low temperatures, and is inflammable.

Amyl Nitrite is almost insoluble in water, but is miscible with alcohol and with ether.

Tests for Identity—Specific gravity: 0.865 to 0.875 at 25° C.

Add 2 cc. of sulphuric acid to a mixture of 2 drops of Amyl Nitrite and 2 drops of water: amyl valerate is produced, recognizable by its odor on dilution with water.

Add a few drops of Amyl Nitrite to a mixture of 1 cc. of ferrous sulphate T.S. and 5 cc. of diluted hydrochloric acid: a greenish-brown color is produced.

Tests for Purity—Mix 1 cc. of normal sodium hydroxide and 10 cc. of distilled water with a drop of phenolphthalein T.S. in a glass-stoppered cylinder, and add 5 cc. of Amyl Nitrite. After inverting the cylinder a few times, the red tint of the aqueous layer is still perceptible (*free acid*).

To a mixture of 1.5 cc. of silver nitrate T.S. and 1.5 cc. of alcohol, add a few drops of ammonia T.S. until the precipitate first formed is redissolved. Then add 1 cc. of Amyl Nitrite, and gently heat for one minute: the mixture does not become brown or black (*aldehyde*).

Assay—Transfer about 3 cc. of Amyl Nitrite, which has been previously shaken with 0.5 Gm. of potassium bicarbonate and carefully decanted to a 100 cc. flask, tared with about 20 cc. of alcohol, and weigh accurately. Add sufficient alcohol to bring the volume to exactly 100 cc. and mix thoroughly. Introduce into a nitrometer, page 1517, exactly 10 cc. of the alcoholic solution, wash any adhering Amyl Nitrite into the nitrometer with 5 cc. of alcohol, followed by 10 cc. of potassium iodide T.S. and afterwards by 5 cc. of diluted sulphuric acid. When the volume of gas has become constant (in about thirty to sixty minutes), note the amount collected, multiply this volume in cc. by 4.8, and divide the product by the weight of the Amyl Nitrite taken. At standard temperature and pressure, the quotient represents the percentage of Amyl Nitrite in the liquid. The temperature correction is 1/273 of the total percentage just found for each degree, additive if the temperature is below 25° C. and subtractive if it is above 25° C. The barometric correction is 1/760 of the total percentage just found for each millimeter, additive if it is above 760 mm. and subtractive if it is below 760 mm.

This assay is explained on page 1481.

Preserve in hermetically-sealed glass bulbs, or in tightly-stoppered vials, in a cool place, protected from light.

Uses—Amyl nitrite is exceedingly volatile. It is a valuable remedy and is much used in asthma, angina pectoris, and similar complaints, by inhalation. It may be administered by dropping a small quantity on a handkerchief and inhaling the vapor or by crushing a glass *pearl of amyl nitrite* in the handkerchief and inhaling the liquid which volatilizes. The official dose is three minims (0.2 cc.).

ÆTHER ACETICUS. N.F. Acetic Ether

[**Æth. Acet.**—Ethyl Acetate]

A liquid containing not less than 96 per cent, by volume, of $C_4H_8O_2$ or $CH_3COO.C_2H_5$ (88.08), the remainder consisting of alcohol and a little water.

Preparation—Hager's process may be used for making this ester: 440 Gm. of official sulphuric acid are added slowly to 250 Gm. of official alcohol contained in a flask, and the mixture allowed to stand for two or three days to permit the formation of ethylsulphuric acid; then 325 Gm. of sodium acetate, previously dried by heating it at a temperature of 130° C., until its weight remains constant, are introduced into a retort connected with a well-cooled receiver; the acid and alcohol mixture is slowly added, heat carefully applied, and the distillation continued as long as vapors of ethyl acetate come over.

$$\underset{\text{sodium acetate}}{NaC_2H_3O_2} + \underset{\text{ethylsulphuric acid}}{C_2H_5HSO_4} = \underset{\text{ethyl acetate}}{C_2H_5C_2H_3O_2} + \underset{\text{acid sodium sulphate}}{NaHSO_4}$$

Ethylsulphuric acid is formed through the action of the sulphuric acid and heat upon the alcohol. This is then decomposed by contact with sodium acetate, while ethyl acetate and acid sodium sulphate are produced.

Description and Physical Properties—Acetic Ether is a transparent, colorless liquid, of a fragrant and refreshing, slightly acetous odor, and a peculiar acetous and burning taste.

Specific gravity: 0.890 to 0.896 at 25° C.

One cc. of Acetic Ether is soluble in about 10 cc. of water at 25° C., miscible with alcohol, ether, or fixed or volatile oils.

Tests for Identity—It does not immediately redden blue litmus paper.

Boiling point: from 72° to 77° C.

Acetic Ether is readily volatilized even at a low temperature. It is inflammable, burning with a yellowish flame.

Tests for Purity—No weighable residue remains on evaporating 10 cc. of acetic ether.

Allow 10 cc. of Acetic Ether to evaporate spontaneously from clean, odorless blotting paper; the final odor does not resemble that of pineapple (*butylic or amylic derivatives*).

Pour carefully 2 cc. of Acetic Ether on 10 cc. of sulphuric acid; no dark ring is developed at the point of contact of the two layers within fifteen minutes (*readily carbonizable organic impurities.*)

Mix 20 cc. of Acetic Ether with a solution of 20 Gm. of sodium hydroxide in 50 cc. of distilled water, allow the mixture to stand, agitating occasionally, or heat it gently under a reflux condenser until a homogeneous liquid results, and then distil about 25 cc. This distillate complies with the test for absence of methanol under Alcohol in the U. S. Pharmacopœia X (see page 905).

Shake 25 cc. of Acetic Ether in a graduated cylinder with 25 cc. of distilled water just previously saturated with Acetic Ether; the ethereal layer when separated measures not less than 24 cc. (*undue proportion of alcohol or water*).

Preserve it in well-stoppered bottles, in a cool place, remote from fire and protected from light.

N. F. Preparations—Elixir Gentianæ Glycerinatum; Elixir Terpini Hydratis et Creosoti; Spiritus Odoratus; Tinctura Antimonii.

Uses—Acetic ether is used only as a flavoring agent. Its odor is frequently noticed in old tinctures and extemporaneous mixtures which have once contained alcohol and acetic acid. Dose, fifteen minims (1 cc.).

CHAPTER LXV

ALDEHYDE, ITS DERIVATIVES AND PREPARATIONS

PARALDEHYDUM. U.S. Paraldehyde
[Paraldehyd.—Paracetaldehyde]

A polymer $[(CH_3.CHO)_3 = 132.13]$ of acetaldehyde.

Preparation—This official liquid is a product of the condensation of three molecules of ordinary aldehyde; it may be made by treating acetaldehyde with small quantities of sulphur dioxide, hydrochloric acid, carbonyl chloride, or zinc chloride; almost complete conversion occurs, and by freezing the liquid and rectifying, pure paraldehyde is produced.

Description and Physical Properties—A colorless, transparent liquid. It has a strong, characteristic, not unpleasant or pungent odor, but a disagreeable taste.

One cc. of Paraldehyde is soluble in about 8 cc. of water at 25° C. One cc. is soluble in 17 cc. of boiling water. It is miscible with alcohol, chloroform, ether, and with volatile oils.

Tests for Identity—Specific gravity: about 0.990 at 25° C.

It boils between 120° and 125° C.

Congealing point: not below 9° C.

When heated with a small quantity of sulphuric acid, Paraldehyde is converted into acetaldehyde, recognizable by its odor.

Tests for Purity—Heat 5 cc. of Paraldehyde on a water bath: no disagreeable odor is noticeable as the last portions evaporate (*impurities derived from fusel oil*) and not more than 0.003 Gm. of residue remains.

One cc. of Paraldehyde forms with 10 cc. of distilled water at 25° C. a clear solution, free from oily drops (*amyl alcohol*). A 5 cc. portion of this solution, acidulated with a drop of hydrochloric acid, yields no turbidity on the addition of 3 drops of barium chloride T.S. (*sulphate*). Another 5 cc. portion, acidulated with 1 drop of nitric acid, yields no opalescence at once on the addition of 3 drops of silver nitrate T.S. (*chloride*).

A mixture of 6 cc. of Paraldehyde and 8 cc. of alcohol with 1 drop of phenolphthalein T.S. acquires a pink color upon the addition of 0.5 cc. of normal sodium hydroxide (*free acid*).

Shake 5 cc. of Paraldehyde with 5 cc. of potassium hydroxide T.S. and allow the mixture to stand at 20° C.: the aqueous layer is not colored yellow or brown within thirty minutes (*acetaldehyde*).

Preserve in well-closed containers, in a cool place, protected from light.

Uses—Paraldehyde is a hypnotic. Owing to its unpleasant taste, it is usually prescribed in combination with alcoholic liquors, elixirs, etc. Dose, thirty minims to one fluidrachm (2 to 4 cc.).

LIQUOR FORMALDEHYDI. U.S. Solution of Formaldehyde
[Liq. Formaldehyd.]

An aqueous solution containing not less than 37 per cent of H.CHO(30.02) with variable amounts of ethyl or methyl alcohol, or both, to prevent polymerization.

Preparation—This liquid, commonly known as *formaldehyde* or *formalin*, is made by mixing the vapor of boiling methyl alcohol, while under pressure, with air in proper quantity, and allowing the mixed vapors to pass over heated copper tubes, and then condensing the vapors by passing them into a copper tank provided with the means for cooling the temperature to 0° C.

The reaction is expressed by the following equation:

$$\underset{\text{methyl alcohol}}{2HCH_2OH} + \underset{\text{oxygen}}{O_2} = \underset{\text{formaldehyde}}{2HCHO} + \underset{\text{water}}{2H_2O}$$

Sufficient water is added to the product to make it contain 37 per cent by weight of absolute formaldehyde.

Description and Physical Properties—A clear, colorless or nearly colorless liquid, having a pungent odor. Its vapor irritates the mucous membrane of the throat and nose.

On long standing, especially in the cold, Solution of Formaldehyde sometimes becomes cloudy, due to the separation of paraformaldehyde.

It is miscible with water and alcohol.

Tests for Identity—Dilute 2 cc. of Solution of Formaldehyde with 10 cc. of distilled water in a test tube, and add 1 cc. of silver ammonium nitrate T.S.: metallic silver is produced either in the form of a finely divided gray precipitate, or as a bright metallic mirror on the sides of the test tube.

Add 2 drops of Solution of Formaldehyde to 5 cc. of sulphuric acid in which about 0.02 Gm. of salicylic acid has been dissolved, and warm the liquid very gently: a permanent, deep red color appears.

Test for Purity—Not more than 1 cc. of normal sodium hydroxide is required to neutralize 20 cc. of Solution of Formaldehyde, using 2 drops of phenolphthalein T.S. as indicator (*free acid*).

Assay—Transfer 3 cc. of Solution of Formaldehyde to a tared flask containing 10 cc. of distilled water, tightly stopper, and weigh accurately. Add 50 cc. of normal sodium hydroxide, and follow this immediately but slowly through a small funnel with 50 cc. of hydrogen dioxide T.S. which has previously been rendered neutral to litmus T.S. with sodium hydroxide T.S. Heat the mixture cautiously on a water bath for five minutes, shaking it occasionally. Allow the mixture to cool, rinse the funnel and sides of the flask with distilled water, and, after allowing it to stand thirty minutes, titrate with normal sulphuric acid, using litmus T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.03002 Gm. of H.CHO.

This assay is explained on page 1454.

Preserve in a moderately warm place, protected from light.

Uses—Solution of formaldehyde or "Formalin" is extensively used as a disinfectant and deodorant. Its employment for preserving milk, meat, and other articles of food likely to spoil through fermentation, is prohibited by both National and State laws. It is, however, used for disinfecting apartments which have been subjected to infection by spraying it on sheets hung in the room or the vapor may be conducted into the room from a generator, of which there are numerous forms on the market (see Disinfectants, page 1866).

PARAFORMALDEHYDUM. U.S. Paraformaldehyde

[**Paraform.**—Paraform, Trioxymethylene]

Paraformaldehyde contains not less than 95 per cent of $(HCHO)_3$ (90.06).

Preparation—It is prepared by evaporating an aqueous solution of formaldehyde until it polymerizes in white masses.

Description and Physical Properties—White, friable masses, or a white powder, having a slight odor of formaldehyde.

Paraformaldehyde is very slowly soluble in cold water, more readily soluble in hot water, with the formation of formaldehyde; insoluble in alcohol and in ether; soluble in solutions of fixed alkali hydroxides.

Paraformaldehyde, when heated, is partly converted into formaldehyde and partly sublimed unchanged.

Tests for Identity—Add 10 drops of sulphuric acid to a mixture of about 0.01 Gm. each of Paraformaldehyde and morphine sulphate: a violet color is produced.

Gently warm about 0.02 Gm. of Paraformaldehyde with 5 cc. of sulphuric acid in which about 0.1 Gm. of salicylic acid has been dissolved: a deep red color develops.

Tests for Purity—Shake 0.5 Gm. of Paraformaldehyde, finely powdered, with 10 cc. of distilled water: the water remains neutral to litmus paper.

Ash: not more than 0.1 per cent.

Assay—Mix about 1 Gm. of Paraformaldehyde, finely powdered and accurately weighed, with 50 cc. of normal sodium hydroxide in a 250 cc. flask, and add immediately, but slowly, through a small funnel, 50 cc. of solution of hydrogen dioxide which has been previously rendered neutral to litmus T.S. with sodium hydroxide T.S. When the reaction has ceased and the foam subsided, rinse the funnel and the sides of the flask with distilled water, allow the liquid to stand for half an hour, and then determine the excess of alkali with normal sulphuric acid, using litmus T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.03002 Gm. of $(HCHO)_3$.

This assay is explained on page 1454.

Preserve in well-closed containers, in a cool place, protected from light.

Uses—Paraldehyde has been used in throat lozenges. It is also employed for the generation of formaldehyde, by heating in an open vessel, over a direct flame.

METHENAMINA. U.S. Methenamine

[**Methenam.**—HEXAMETHYLENAMINA, U.S.P. IX, HEXAMETHYLENETETRAMINE]

Methenamine contains not less than 99 per cent of $(CH_2)_6N_4$ (140.16).

Preparation—Made by passing a current of dry ammonia gas over warm trioxymethylene (paraformaldehyde) and purifying the product.

It is also prepared by evaporating to dryness, under reduced pressure, a mixture of stronger ammonia water and solution of formaldehyde and recrystallizing the residue from dehydrated alcohol. The reaction is illustrated by the following equation:

$$\underset{\text{formaldehyde}}{6HCHO} + \underset{\text{ammonia}}{4NH_3} = \underset{\substack{\text{hexamethylene}\\\text{tetramine}}}{(CH_2)_6N_4} + \underset{\text{water}}{6H_2O}$$

Description and Physical Properties—Colorless, lustrous crystals, or a white, crystalline powder. It is odorless.

One Gm. of Methenamine is soluble in 1.5 cc. of water, 12.5 cc. of alcohol, and in about 10 cc. of chloroform, at 25° C.

At about 263° C. it sublimes without melting, partly decomposing and evolving a disagreeable odor. When brought into contact with fire, it readily ignites, burning with a smokeless flame.

Tests for Identity—An aqueous solution of Methenamine is alkaline to litmus paper.

Heat an aqueous solution of Methenamine (1 in 10) with diluted sulphuric acid: it decomposes with the liberation of formaldehyde, recognized by its odor or by its darkening paper moistened with silver ammonium nitrate T.S. On the subsequent addition of an excess of solution of sodium hydroxide, ammonia is liberated.

Tests for Purity— Ash: not more than 0.05 per cent.

Add 1 cc. of alkaline mercuric potassium iodide T.S. to 10 cc. of an aqueous solution of Methenamine (1 in 20): no darker color is produced than results from the addition of the same amount of the reagent to 10 cc. of distilled water (*ammonium salts*).

An aqueous solution of Methenamine (1 in 50) does not become colored or turbid when mixed with an equal volume of hydrogen sulphide T.S. (*heavy metals*).

The addition of 5 drops of barium chloride T.S. to 10 cc. of an aqueous solution of Methenamine (1 in 50), acidulated with 5 drops of hydrochloric acid, produces no turbidity within one minute (*sulphate*).

One Gm. of Methenamine shows no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid, page 1520.

Assay—Place about 1 Gm. of Methenamine, accurately weighed, in a beaker, add 40 cc. of normal sulphuric acid, and evaporate on a water bath (or boil gently, adding a little distilled water from time to time, if necessary) until the odor of formaldehyde is no longer perceptible. Cool, add 20 cc. of distilled water, and titrate the excess of acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.03504 Gm. of $(CH_2)_6N_4$.

This assay is explained on page 1458.

Preserve in well-closed containers.

Uses—Hexamethylenamine is marked under many trade names among which are *urotropine*, *cystogen*, *hexamine*, *formin*, *aminoform*, *cystamine*, and *uritone*. It is employed chiefly as a urinary antiseptic. It is occasionally prescribed in "colds". It is given in doses of from four to fifteen grains (0.25 to 1 Gm.).

A tablet of hexamethylenamine may be conveniently used as a source of heat at the bedside or under other conditions where ordinary means of heating are not available. It may be ignited by a burning match and burns with a practically smokeless flame. While a tablet burns for only a few moments it is long enough to heat a small amount of water for a hypodermic injection or a test.

Unofficial Compound of Hexamethylenamine

Amphotropin—Hexamethylene-tetramine Camphorate—$[(CH_2)_6N_4]_2.C_8H_{14}(COOH)_2$—A molecular combination of camphoric acid and hexamethylene-tetramine.

A light, white, crystalline powder, soluble in water, alcohol, and chloroform, but almost insoluble in ether and benzene. The aqueous solution is acid.

Actions and Uses—Amphotropin combines the actions of camphoric acid and hexamethylenamine, but is effective in smaller doses. It acts as a urinary antiseptic, induces diuresis, and increases the elimination of uric acid in pathologic conditions.

Dose—Eight grains (6.5 Gm.), three times daily.

Manufactured by H. A. Metz Laboratories.

Unofficial Organic Compounds

Acetal (Diethylacetal, Diethylaldehyde, Ethylenediethyl Ether), $CH_3—CH(OC_2H_5)_2$
: Obtained from reaction between acetaldehyde and alcohol in the presence of dehydrating agents. Soluble in 20 parts of water, and in all proportions of alcohol and ether. Used as a hypnotic in doses of two fluidrachms (8 cc.)

Acetbromanilid, Antisepsin, $C_6H_4Br.NH(C_2H_3O)$
: Prepared by adding 160 parts bromine to a solution of 135 parts of acetanilid in glacial acetic acid, and crystallizing the precipitate from hot alcohol. Colorless needles, tasteless, owing to their sparing solubility. Antipyretic and analgesic. Dose, three to ten grains (0.2 to 0.65 Gm.)

Acetylphenylhydrazin, $C_6H_5NH = NHCH_3CO$ (Pyrodin, Hydracetin)
: Antipyretic. Powerful remedy. Dose, one-half to one grain (0.03 to 0.065 Gm.) per day

Agathin, $C_6H_4(OH)CH = N.N(CH_3)C_6H_5$ (Salicyl-alpha-methyl-phenylhydrazine)
: A yellowish, crystalline salt; insoluble in water, soluble in alcohol. Antiseptic and anti-neuralgic. Dose, eight to ten grains (0.5 to 0.6 Gm.)

Aldehyde (Acetaldehyde), C_2H_4O
: By gently warming a mixture of alcohol, manganese dioxide, sulphuric acid, and water, and collecting the vapor which is formed by means of a condenser. If exposed, it will gradually be converted into acetic acid. It is a colorless, thin, and very inflammable liquid, having an ethereal odor, and the sp. gr. 0.805

Alphol (Alphanaphthol Salicylate) $C_6H_4.OH.COOC_{10}H_7$
: A reddish-white powder, soluble in alcohol and ether. It is used in doses of from eight to fifteen grains (0.5 to 1 Gm.) in rheumatism and as an intestinal antiseptic

Alphozone, Succinic Dioxide
: Prepared by the interaction of a strong solution of hydrogen peroxide and succinic anhydride. A fluffy white, crystalline powder, odorless. Used as a germicide and antiseptic in solutions of from 1 to 3000 to 1 to 1000

Alumnol N.N.R. (Aluminum Beta-naphtholdisulphonate), $(C_{10}H_5(OH)(SO_3)_2)_3Al_2$
: A white powder, soluble in water and glycerin, slowly soluble in alcohol. It is used as an antiseptic and astringent; mixed with from 5 to 10 parts of starch in the form of a dusting powder and, in from 1 to 5 per cent solution, as a wash

Amygdophenin (Phenetidin Amygdalate) $C_6H_4.OC_2H_5NH.CO.CH.OH.C_6H_5$
: Prepared by heating *p*-phenetidin with mandelic acid until all of the water is expelled, washing the product with diluted sodium hydroxide solution and crystallizing from ether-alcohol mixture. White, crystalline powder or glistening scales. Used in rheumatic fever. Dose, ten to fifteen grains (0.65 to 0.97 Gm.) every 4 or 5 hours

Amyl Acetate, $C_5H_{11}.C_2H_3O_2$
: By distilling amyl alcohol with an acetate and sulphuric acid. It is, when pure, a colorless liquid having a very fragrant pear-like odor. Insoluble in water. Sp. gr. 0.876. Used as a solvent for resins, pyroxylins, lacquers, and varnishes

Amyl Alcohol, $C_5H_{11}OH$
: See reagents, Chapter XCII

Amyl Butyrate, $C_5H_{11}.C_4H_7O_2$
: Sp. gr. 0.852. Fragrant odor

Amyl Chloride, $C_5H_{11}.Cl$
: By the action of strong hydrochloric acid upon amylic alcohol. Sp. gr. 0.874

Amyl Iodide, $C_5H_{11}.I$
: By acting upon amylic alcohol with iodine and phosphorus. It is a colorless, transparent liquid, of a faint odor and a pungent taste. Sp. gr. 1.509

Amyl Valerate, $C_5H_{11}.C_5H_9O_2$
: Sp. gr. 0.864. Odor of apples. Used as a sedative and as a solvent for cholesterin. Dose, two to three grains (0.1 to 0.2 Gm.)

Amylene (Valerene, Pentene, Pental), $(CH_3)_2C.CH.CH_3$
: A colorless liquid, having a peculiar, disagreeable odor; density, 0.655 at 10° C. (50° F.). Anesthetic. Too dangerous for use

Amylene-chloral Solution (50 per cent)
: Used much like that of chloral, but less powerful. A hypnotic. Dose, eight to forty-five minims (0.5 to 3 cc.)

Anthrasol, Purified or Colorless Coal Tar
: A thin, mobile, light-yellow, oily fluid, freed from pyridin and chinoline by acid treatment and from pitch by distillation; insoluble in water but miscible with oils and fats. Used as an antiseptic parasiticide in form of 5 to 30 per cent ointment

Antithermin (Phenylhydrazin-levulinic Acid), $C(CH_3).C_6H_5N_2H.C_3H_5O_2$
: In colorless crystals, insoluble in cold water. Used as an antipyretic, but with caution because of depressant action. Dose, 3 grains (0.2 Gm.)

Antitussin Di-fluor-di-phenyl $(C_6H_4F.)_2$
: Used in whooping cough, by inunction in the form of a 5 per cent ointment

Apolysin (Monophenetidin Citrate) $C_6H_4{<}^{OC_2H_5}_{NH.CO.C_3H_4(OH)(COOH)_2}$
: A yellowish-white, crystalline powder, sparingly soluble in water and glycerin. It resembles the phenacetin chemically and medicinally, being used as an antipyretic and analgesic in doses of from 8 to 30 grains (0.5 to 2 Gm.)

Argentamine, (Ethylene-Diamine Silver Nitrate)
: An aqueous solution of ethylene-diamine and 10 per cent silver nitrate. Said to be non-irritating. An antiseptic and astringent like other silver salts. It is also used as a dusting powder and in ointments and suppositories. Used in 1 to 5 per cent solution

Asaprol (Beta-naphthol-alpha-mono-sulphonate of Calcium, Abrastol), $(C_{10}H_6.OH.SO_3)_2Ca+3H_2O$
: A colorless, pale-reddish powder without odor, soluble in about 2 parts of water and 3 parts of alcohol. Used as an antipyretic and analgesic in acute muscular rheumatism in doses of 5 to 15 grains (0.3 to 1 Gm.)

Benzacetin, Acet-amido-ethyl-salicylic Acid
: Colorless crystals; soluble in alcohol and aqueous alkaline solutions. An analgesic. Dose, 8 to 15 grains (0.5 to 1 Gm.)

Benzamine Lactate (Br. 1914) $C_{15}H_{21}NO_2.C_3H_6O_3$
: A white, crystalline powder used the same as alpha- and beta-eucaine, being more soluble than either of these salts

Benzanilid (Phenylbenzamide, Benzoylanilid) $C_6H_5NHCO_6H_5$
: Obtained by the action of benzoyl chloride on aniline in the presence of sodium hydroxide. A pinkish powder, soluble in alcohol, insoluble in water. Used as an antipyretic for children in doses of one-half to five grains (0.03 to 0.32 Gm.)

Unofficial Organic Compounds—*Continued*

Benzonaphthol, N. N. R. (Benzoyl-naphthol, Benzoate of Naphthol, Betanaphthol Benzoate) $C_6H_5CO_2-C_{10}H_7$	Colorless needles, or a white, tasteless, crystalline powder, having a faintly aromatic odor. Almost insoluble in water, very soluble in alcohol and in ether, also soluble in chloroform and in fixed oils. Antiseptic. Dose, 4 to 8 grains (0.25 to 0.5 Gm.), repeated frequently
Benzosalin (Benzoyl-salicylic-acid-methyl Ester) $C_6H_4O(CH_3).CO.O.(C_6H_5CO)$, 1 : 2	White, acicular crystals; insoluble in water, readily soluble in alcohol. Incompatible with acids. Said to decompose in the intestines into benzoic and salicylic acids. Used in rheumatism, neuritis and neuralgia. Dose, 8 to 60 grains (0.5 to 4.0 Gm.)
Benzosol (Guaiacol Benzoate, Benzoyl-guaiacol). $C_6H_4O\langle^{O.CH_3}_{O—C_6H_5.CO}$	White, crystalline powder, odorless and tasteless, soluble in alcohol, but insoluble in water. It contains about 54 per cent of guaiacol and is used as an internal antiseptic in phthisis, in doses of from 4 to 10 grains (0.25 to 0.65 Gm.)
Benzyl Benzoate, N. N. R. Benzylis Benzoas $C_6H_5COO.CH_2C_6H_5$	The benzyl alcohol ester of benzoic acid. It contains not less than 95 per cent benzyl benzoate A colorless oily liquid above about 20° C. It is odorless, or has a faint aromatic odor, and a sharp burning taste. It is insoluble in water or glycerin but miscible in all proportions with alcohol, chloroform, and ether. Benzyl benzoate boils at from 320° to 325° C. with partial decomposition. When ignited it burns with a very smoky flame. Sp. gr. 1.09 to 1.13 at 15°C., 1.083 to 1.122 at 25° C. For further tests see the N. N. R. 1925 *Uses*—In dysmenorrhea and intestinal colic. Dose, from 5 to 8 minims (0.3 to 0.5 cc.)
Benzyl Fumarate-Abbott, N. N. R. Benzylis Fumaras, Dibenzyl Fumarate $C_6H_5CH_2.OOC.OH : CH.COO.CH_2C_6H_5$	It contains not less than 99 per cent of benzyl fumarate A white, crystalline solid; odorless; almost tasteless. It is almost insoluble in water; soluble in alcohol, ether and chloroform; also soluble in the fixed and volatile oils. It melts at 58.5 to 59.5°C. The solution of benzyl fumarate in chloroform (1 : 25) should be clear and colorless For further tests see the N. N. R. 1925 *Uses*—See *Benzyl Benzoate*. Dose, in from 5 to 20 grains (0.3 to 1.3 Gm.) Manufactured by The Abbott Laboratories.
Benzyl Succinate, N. N. R Benzylis Succinas, Dibenzyl Succinate $C_6H_5CH_2.OOC.CH_2.CH_2.COO.CH_2.C_6H_5$	The dibenzyl ester of succinic acid. It contains not less than 99 per cent of benzyl succinate. A white, or faintly yellowish-white, crystalline powder; odorless; almost tasteless; permanent in the air. Almost insoluble in water, soluble in alcohol, ether and chloroform; also soluble in the fixed and volatile oils For additional tests see the N. N. R. 1925. *Uses*—See *Benzyl Benzoate*. Dose, 5 to 15 grains (0.3 to 1 Gm.) Prepared by Hynson, Westcott and Dunning.
Betanaphthol Salicylate, N. N. R. (Betol Naphthalol, Naphthosalol, Salinaphthol), $C_6H_4(OH)COO.C_{10}H_7$	White, odorless, tasteless powder, insoluble in water, but soluble in alcohol and ether. It is used as an internal antiseptic and anti-rheumatic in doses of from 4 to 10 grains (0.25 to 0.65 Gm.)
Bismal, (Bismuth Methylene-digallate) $4(C_{15}H_{12}O_{12}).3\ Bi(OH)_3$	Prepared by digesting methylene digallic acid with bismuth hydroxide. Used as an astringent in chronic diarrhea in doses of 2 to 5 grains (0.13 to 0.32 Gm.)
Borophenol	Disinfectant. A combination of borax and phenol
Bromal, C_2HBr_3O	Hypnotic. Dose, 3 grains (0.2 Gm.)
Bromalin (Hexamethylene-tetramine Bromethylate) $(CH_2)_6N_4.C_2H_5Br$	Prepared by the interaction between equal parts of ethyl bromide and hexamethylene-tetramine. Used in epilepsy to replace alkaline bromides. Dose, 30 to 60 grains (2 to 4 Gm.)
Bromamide, $C_6H_2Br_3NH_2.HBr$	Prepared by reducing nitro-tribrom-benzene with tin and sulphuric acid. Antipyretic, analgesic, and antirheumatic. Dose, 10 to 15 grains (0.65 to 1 Gm.)
Bromopyrine (Monobromantipyrine), $C_{11}H_{11}BrN_2O$	In white, crystalline needles. Soluble in alcohol and chloroform. Slightly soluble in hot water
Butyl Chloral, $C_4H_5Cl_3O$,	Pass chlorine into aldehyde; this compound is formed in addition to
Butyl Chloral Hydrate, N. N. R. (Croton Chloralhydrate), $C_4H_5Cl_3O.H_2O$	chloral. Butyl chloral is a dense, oily liquid, of peculiar odor. It dissolves when treated with an excess of warm water, and on cooling deposits *butyl chloral hydrate*. Used as a hypnotic in 10 grain (0.65 Gm.) doses
Cacodylic Acid, $(CH_3)_2\ AsO.OH$ (Dimethylarsenic Acid)	Prepared by distilling arsenous acid and potassium acetate together and oxidizing the resulting product with mercuric oxide. Used in the form of the sodium salt in skin diseases
Chinoline, C_9H_7N Quinoline	A colorless, mobile liquid, having a pungent, somewhat bitter-almond odor, and a bitter taste. Sp. gr. 1.081
Chinosol, N.N.R., $(C_9H_7ON)_2\ H_2SO_4$ Oxyquinolin Sulphate	A powerful antiseptic. Dose, internally, 5 grains (0.3 Gm.); nasal spray, 1 to 3000; eye wash, 1 to 4000; gargle, 1 to 250. Manufactured by the Chinosol Company
Chloralformamide, N. N. R. (Chloralamide), $C_3H_4Cl_3NO_2$	It is an addition product of chloral, CCl_3COH, and formamide, $CH(OH)NH$. It is used as a hypnotic in doses of 15 grains (1 Gm.)
Chloralimide, $CCl_3CH–NH$	Prepared by heating chloralamide to the temperature of boiling water, when it decomposes into chloralimide and water. Antipyretic and analgesic. Dose, 3 to 7 grains (0.2 to 0.45 Gm.)
Chloral Menthol (Mentholated Chloral)	An oily, colorless liquid, with a mint-like odor. Sp. gr. 1.984. Counterirritant and local anesthetic
Chlormethylmenthyl Ester, (Forman), $C_{10}H_{19}O.CH_2Cl$	Prepared by the action of formaldehyde on menthol in the presence of hydrochloric acid gas. Used for catarrhal affections of the respiratory passages
Chloralose, $C_8H_{11}Cl_3O_6$	Hypnotic. Dose, 12 grains (0.77 Gm.)

Unofficial Organic Compounds—*Continued*

Chloral Phenol	Prepared by triturating equal parts of phenol and chloral hydrate together. Used as a hypnotic, locally as a counterirritant and anesthetic
Citrophen $C_3H_4(OH)(CONH.C_6H_4OC_2H_5)_3 + 3H_2O$	Prepared by heating a mixture of *p*-phenetidin and citric acid in the presence of a dehydrating agent, washing the product with a very dilute solution of sodium hydroxide and crystallizing from water. A white crystalline powder having an acidulous aromatic taste and acid reaction. Uses identical with acetphenetidin. Dose, 5 to 10 grains (0.32 to 0.65 Gm.)
Creolin	Said to be an emulsion of cresol obtained by means of rosin soap
Cresol Iodide (Losophan), $C_6HI_3(CH_3)OH$	A yellow powder, containing 80 per cent of iodine. Soluble in alcohol, insoluble in water. Used as an external application in skin diseases, in the form of a solution or of an ointment
Dipropylbarbituric Acid, Proponol, $C_{10}H_{16}O_3N_2$	Preparation analogous to that of Veronal. Uses similar to those of Veronal. Dose, 3 to 8 grains (0.2 to 0.5 Gm.)
Eosin, $C_{20}H_8Br_4O_5$	A bronze-colored, crystalline powder, obtained from the action of phthalic acid upon phenols. Eosin is largely used as a dye, and for making a brilliant *red ink*, by dissolving 5 grains in a fluidounce of water in which 10 grains of acacia have been dissolved (see also page 853)
Epicarin, Betanaphtholhydroxytoluic Acid	A parasiticide occurring on the market in pure and impure form, the latter being used in veterinary practice. The pure product is used in skin affections in 10 per cent solution or in 10 to 20 per cent ointment
Erythrol Tetranitrate, N.N.R., $C_4H_6(NO_3)_4$ Tetranitrol	The tetranitrate of erythrite (butane-tetrol), $C_4H_6(OH)_4$. Colorless, crystalline scales, insoluble in cold water, readily soluble in alcohol. It explodes on percussion. Uses, much like nitroglycerin. Action, slower and more lasting. Dose, ½ to 1 gram (0.03 to 0.06 Gm.) Distributed by Merck and Co.
Ethyl Benzoate, $C_2H_5.C_7H_5O$	By heating to 100° C. (212° F.) in a sealed glass tube a mixture of alcohol and benzoic acid. It is a colorless, oily liquid with a pleasant aromatic odor and a pungent taste. Sp. gr. 1.051
Ethyl Bromide, N. N. R., C_2H_5Br	The hydrobromic acid ester of ethyl alcohol, containing approximately 1 per cent of ethyl alcohol Ethyl bromide should be kept in glass stoppered containers and protected from the light, and a bottle when opened should be used at once, as it deteriorates rapidly. (To be preserved carefully in a small, opaque bottle containing not more than 50 cc.) It should not be confounded with ethylene bromide, which is said to be very poisonous. The specific gravity of ethylene bromide is 2.179, while that of ethyl bromide is about 1.45 Ethyl bromide is a colorless, strongly refractive, easily volatile liquid, having a pleasant ethereal odor. It is insoluble in water, but readily soluble in alcohol and in ether. It boils at from 38° to 40° C. Its specific gravity at 15° C. is from 1.453 to 1.457 *Uses*—Ethyl bromide is a rapid anesthetic, acting much like chloroform. The anesthesia is quickly and pleasantly induced and the recovery is rapid, but subsequently the patient may have general mild depression. Pain is abolished before consciousness. The respiration is paralyzed at about the same time as the reflexes, so that the zone of safety is very narrow. It has been recommended for short operations in obstetrics, gynecology and minor surgery, but is not to be used for long operations. It must be regarded as a very dangerous agent in inexperienced hands. Dose, from 45 minims to 3 fluidrachms (3 cc. to 12 cc.) is sufficient to induce anesthesia. It should be administered rapidly with little or no air. The administration requires from twenty to forty seconds; the anesthesia lasts about two minutes. The dose for children should not exceed 1 cc. for each year of age
Ethyl Butyrate, $C_2H_5.C_4H_7O_2$	By heating together a mixture of strong sulphuric acid, butyric acid, and strong alcohol. A transparent, colorless, very thin liquid. It has an odor resembling that of pineapple. Sp. gr. 0.902
Ethyl Carbamate (Urethane) (U. S. P. IX) $C_3H_7O_2N$ or $CO(OC_2H_5)NH_2$	The ethyl ester of carbamic acid. Preserve it in well-closed containers. It is made by acting upon *urea nitrate* with alcohol in excess, in closed vessels at a temperature of 120° to 130° C. Colorless, columnar crystals or scales. Odorless and having a cooling, saline taste. Its aqueous solution (1 in 20) is neutral to litmus. One Gm. of Ethyl Carbamate dissolves in 0.45 cc. of water, 0.8 cc. of alcohol, 2.5 cc. of glycerin, 9.9 cc. of chlorofo m, 1.5 cc. of ether, and in 32 cc. of olive oil, at 25° C. It is used as a hypnotic in doses of 15 grains (1 Gm.)
Ethyl Cyanide (Hydrocyanic Ether, Propionitrile), C_3H_5N, or $C_2H_5.CN$	A colorless liquid. Sp. gr. 0.78. Very poisonous, but less so than hydrocyanic acid, with which it agrees in therapeutic action and dose
Ethyl Disulphide, C_2H_5S	By acting upon potassium disulphide in concentrated solution with potassium sulphethylate. A colorless, oily liquid, having a very strong odor and a sharp, sweetish taste
Ethyl Formate, (Formic Ether) $C_2H_5CHO_2$	Prepared by distilling sodium formate, alcohol and strong sulphuric acid together. Causes muscular relaxation and anesthesia when inhaled
Ethyl Iodide, C_2H_5I	By acting upon alcohol with iodine and phosphorus. A colorless, volatile liquid, but gradually turning brown in the light. Slightly soluble in water. Sp. gr. 1.946. Anesthetic, antispasmodic, and stimulant. Dose, fifteen drops three or four times a day, inhaled from a handkerchief

Unofficial Organic Compounds—*Continued*

Ethyl Pelargonate (Grape Oil), $C_2H_5.C_9H_{17}O_2$	By adding sulphuric acid and water to wine lees, and distilling in a current of steam. A colorless, mobile liquid, of a strong vinous odor. Almost insoluble in water, but soluble in alcohol. Sp. gr. 0.860
Ethylproprionyl, (Diethylketone) $C_5H_{10}O$	Prepared by the dry distillation of calcium proprionate; it can also be prepared by distilling sugar with an excess of lime. Hypnotic. Dose, 8 to 45 minims (0.5 to 3 cc.) largely diluted
Ethyl Salicylate, $C_6H_4.OH.CO.O.(C_2H_5)$	Analogous to methyl salicylate, has the same action but less irritating and toxic. Dose, 5 to 10 minims (0.3 to 0.6 cc.)
Ethyl Sulphydrate (Mercaptan), $C_2H_5.HS$	By distilling crystallized calcium sulphethylate with a solution of barium sulphydrate, collecting the product in a well-cooled receiver, then decanting the aqueous portion and purifying the mercaptan by distilling with mercury and dehydrating by calcium chloride. A colorless, very mobile liquid, having an alliaceous odor
Ethylsulphuric Acid (Sulphovinic Acid), $C_2H_5.HSO_4$	By reacting upon sulphuric acid with alcohol. It is produced during the preparation of ether
Ethyl Valerate, $C_2H_5.C_5H_9O_2$	A colorless liquid having a fruity odor, and also one like that of valerian. Sp. gr. 0.866. It is also called ethyl valerianate
Ethylene for Anesthesia, N. N. R. Aethylenum pro Narcosi	It contains not less than 98 per cent by volume of ethylene (CH_2: CH_2)
	Ethylene for anesthesia is a colorless gas possessing a slightly sweet odor and taste which is offensive to some. It is somewhat lighter than air. Pure ethylene is solid at below −169.4° C. and boils at −103.9° C. The gas is inflammable and a mixture of it and oxygen explodes when brought in contact with a flame or an electric spark
	Uses—A considerable number of trials give promise that ethylene is of value for the production of surgical anesthesia and that it has advantages over nitrous oxide. These advantages are stated to be equally rapid but more pleasant induction, satisfactory relaxation without cyanosis or sweating and rapid recovery
	Dose—Ethylene for anesthesia is supplied in compressed state in metal cylinders. For use the gas is passed into an inhalation apparatus and is then inhaled with or without admixture of oxygen. The concentration employed for surgical anesthesia is generally 90 per cent ethylene and 10 per cent oxygen, though after a prolonged period of anesthesia, a deep anesthetic state may be maintained on 80 per cent ethylene. To avoid accidental explosion, ethylene for anesthesia must not be brought in contact with a naked flame or an electric spark
	Manufactured by the U. S. Industrial Chemical Company, New York (Ohio Chemical and Manufacturing Company, Cleveland, distributor)
Ethylene Bromide, $C_2H_4.Br_2$	Contains 90.9 per cent of bromine. Dose, six drops three times a day. Used in epilepsy
Ethylene Diamine, $C_2H_4(NH_2)_2$	Prepared by heating ethylene bromide with an excess of alcoholic ammonia, filtering, evaporating to dryness and distilling the residue with potassium hydroxide. Used as a solvent for the false membrane in diphtheria in 2 per cent solution
Ethylidene Chloride, (Aran's Ether, Wigger's Ether, Ethydene Chloride), CH_3CHCl_2	A colorless liquid, somewhat resembling chloroform. Sp. gr. 1.175 at 17° C. (62.6° F.); boiling at 60° C. (140° F.). Anesthetic
Eucodin, (Methyl-codeine Bromide) $C_{18}H_{21}O_3N(CH_3)Br$	Used as a sedative as a substitute for codeine, especially in cough. Dose, one grain (0.065 Gm.)
Eudoxin (Tetra-iodo-phenolphthalein Bismuth)	A bismuth salt of nosophen containing about 52.9 per cent of iodine and 14.5 per cent of bismuth. Odorless, tasteless, insoluble powder, used as an intestinal antiseptic in doses of three to eight grains (0.2 to 0.5 Gm.)
Eugoform (Acetylized Methylene Diguaiacol)	Prepared from guaiacol by the action of formaldehyde and acetylization. Used as an antiseptic in form of a dusting powder and ointment
Eumydrin (Methylatropine)	Prepared by the treatment of methyl atropine with nitric acid. Used as a mydriatic, internally as an antihidrotic in doses of one-sixtieth to one-twenty-fourth grain (0.001 to 0.0025 Gm.)
Euphorin, N. N. R. (Phenyl Urethane), $CO\begin{matrix}/OC_2H_5\\ \backslash NH(C_6H_5)\end{matrix}$	Colorless, crystalline powder, soluble in alcohol and ether, slightly soluble in water. Prepared by the interaction of aniline and ethyl chloroformate purified by recrystallization from diluted alcohol. Antipyretic, antiseptic, antirheumatic, and analgesic. Dose, 8 grains (0.5 Gm.), equivalent to 15 grains (1 Gm.) of antipyrine
Euphthalmine (Phenylglycoll-N-methyl-β-vinyl-diacetonalkamine)	Prepared by methylating vinyldialkamine and treating the resulting compound with a very dilute solution of mandelic acid. Used as an active mydriatic in from 2 to 10 per cent solutions
Euphthalmine (Hydrochloride) (Phenylglycolyn-methyl-vinyl-diacetonalkamine Hydrochloride)	A derivative of beta-eucaine, said to resemble atropine in its effect upon the system, producing prompt mydriasis without anesthetic action or pain. Use two to three drops of a 5 to 10 per cent solution
Eupyrine, Vanillin-ethylcarbonate-para-phenetidin	Light-yellow needle-shaped crystals, tasteless and having a faint odor of vanillin. Used as a non-toxic antipyretic in doses of from 15 to 30 grains (1.0 to 2.0 Gm.) once or twice daily
Euresol, Resorcin Monoacetate $C_6H_4(OH)OCOCH_3$	The action is similar to that of resorcinol but milder and more lasting. Used in from 5 to 20 per cent ointments
Europhen (Di-isobutyl-ortho-cresol-iodide), $C_6H_3(CH_3)(C_4H_9)O\diagdown\diagup HI$ $C_6H_3(CH_3)(C_4H_9)O\diagup$	A yellow, amorphous powder having an aromatic odor; soluble in alcohol, ether, and fixed oils, but insoluble in water. Used as an antiseptic dusting powder or in 5 to 10 per cent ointments. (Similar to thymol iodide)

Unofficial Organic Compounds—*Continued*

Exalgine (Methylacetanilid) $C_6H_5N(CH_3)CH_3CO$, or $C_9H_{11}NO$	Antipyretic, analgesic, and antispasmodic. Dose, 3 to 6 grains (0.2 to 0.38 Gm.), not more than twelve grains being given in twenty-four hours
Fluorescein, $C_{20}H_{12}O_5 + H_2O$	Yellowish-red or dark red powder. Soluble in alcohol with yellow-red color and green fluorescence. Used to detect foreign bodies in the eye (see also page 853)
Formanilid (Phenylformamide) $C_6H_5NH.HCO$	Prepared by heating analine with ethyl formate. Colorless prisms, soluble in water, glycerin, and fixed oils; readily soluble in alcohol. Antipyretic and analgesic in doses of from 2 to 5 grains (0.13 to 0.32 Gm.). Locally applied to mucous membrane it produces anesthesia
Formylphenetidin $C_6H_4(OC_2H_5)NH.COH$	Colorless, odorless, tasteless crystalline scales. An antiseptic and analgesic. Dose, 5 grains (0.32 Gm.)
Fuchsin (Rosaniline), $C_{20}H_{19}N_3$	A non-volatile, colorless, bitter substance, produced whenever a mixture of aniline and toluidine is heated to about 180° C. (356° F.) with an oxidizing agent of moderate power, as, for example, arsenic trioxide. The solutions of some of its acid salts are used largely for dyeing silk and wool a magnificent crimson (see also page 853)
Gallacetophenone, $C_6H_2\begin{cases}(OH)_3\\CH_3CO\end{cases}$	Proposed as a substitute for pyrogallol as a local application
Gallanilid, Gallanol, $C_6H_5NH.CO.C_6H_2(OH)_3 + 2H_2O$	Prepared by heating gallic acid with an excess of analine at 150° C. (302° F.) the mixture treated several times with diluted hydrochloric acid and crystallizing from boiling water. Colorless, crystals, readily soluble in alcohol, ether and boiling water, sparingly soluble in cold water. Used in skin affections as a substitute for chrysarobin in 10 to 20 per cent solution or ointment
Gallobromol, Dibromgallic Acid $C_6Br_2(OH)_3COOH$	A substitution compound of gallic acid. Used in place of potassium bromide as a sedative in cases of epilepsy in doses of 10 to 30 grains (0.65 to 2.0 Gm.)
Geosote (Guaiacol Valerate)	The guaiacol ester of valeric acid; yellow, oily liquid of smoky odor and burning taste. Used as an antitubercular and intestinal disinfectant in three- to ten-minim (0.2 to 0.6 cc.) doses
Guaethol (Ajacol, Thanatol, Pyrocatechin-mono-ethyl Ether), $C_6H_4\begin{cases}OC_2H_5\\OH\end{cases}$	An oleaginous fluid, congealing to a crystalline mass at low temperatures, soluble in alcohol and ether. Similar to guaiacol in medicinal properties. Dose, 2 to 4 grains (0.13 to 0.25 Gm.)
Guaiacetin (Sodium Pyrocatechin Monoacetate) $C_6H_4.(OH).OCH_2COONa$	A white powder used in the treatment of tuberculosis and chronic bronchitis. Dose, 8 grains (0.5 Gm.)
Guaiacol Cinnamate (Styracol) $C_6H_4(OCH_3)C_9H_7O_2$	Colorless, needle-shaped crystals used in catarrhal affections of the digestive tract and in the treatment of phthisis. Dose, 15 grains (1 Gm.)
Guaiacol Salicylate, Guaiacol Salol $C_6H_4(OCH_3)C_7H_5O_3$	This compound is analogous to salol. Used as an intestinal antiseptic. Dose, 15 grains (1 Gm.)
Guaialin (Methylene Diguaiacol-benzoic Ester)	An antipyretic and alterative tonic in tubercular affections
Guaiasanol (Diethylglycocoll-guaiacol Hydrochloride)	Small, colorless, prismatic crystals. Used as an antiseptic and anesthetic in the treatment of intestinal and pulmonary tuberculosis. Dose, 15 to 45 grains (1 to 3 Gm.)
Halazone (Para-toluolsulphon-dichloramino-benzoic Acid, Dakin-Dunham Tablets)	This tablet is used for the sterilization of water for drinking purposes. One-fourth of a milligramme (0.00025 Gm.) of Halazone will sterilize one quart of water in from fifteen to sixty minutes
Hedonal (Methyl-propyl-carbinol Urethane)	Used as a hypnotic in treatment of insomnia due to mental overwork. Dose, 15 to 30 grains (1 to 2 Gm.)
Helmitol (Hexamethylene-tetramine-anhydro-methylene Citrate)	Colorless crystals, soluble in 15 parts of water, slowly soluble in alcohol. Used as a urinary antiseptic in doses of 15 grains (1 Gm.)
Hetocresol, Metacresol Cinnamate $C_6H_5CH{=}CH.COOC_3H_4CH_3$	A white, crystalline powder recommended for use in tuberculosis of the bladder in form of ½ per cent suspension
Hetralin (Resorcin Hexamethylene-tetramine, $C_6H_6O_2(CH_2)_6N_4$	White, needle-shaped crystals. Used in the treatment of gonorrhea, cystitis, etc. Dose, 15 to 30 grains (1 to 2 Gm.)
Holocaine Hydrochloride (Ethenyl-paradiethoxy-diphenyl-amidine Hydrochloride) $C_6H_4OC_2H_5NH.C(CH_3) : N.C_6H_4.OC_2H_5.HCl$	A colorless, odorless, neutral crystalline powder, used as a substitute for cocaine in ophthalmic practice. Five minims of a 1 per cent solution when introduced into the eye produces anesthesia in from 1 to 10 minutes
Hydro-quinone, (Hydrochinone) $C_6H_4(OH)_2 1:4$	Prepared by oxidizing aniline with chromium trioxide mixture. An antiseptic and antipyretic. Dose, 5 to 10 grains (0.3 to 0.6 Gm.). Largely used as a developer in photography
Hypnone (Acetophenone), C_8H_8O or $C_6H_5.CO.CH_3$	A colorless liquid, having an almond-like odor, insoluble in water or glycerin, soluble in alcohol and ether. A hypnotic; dose 10 to 20 minims (0.6 to 1.2 cc.)
Ichthalbin (Ichthyol Albuminate)	A grayish-brown, odorless powder, insoluble in ordinary solvents, but soluble in alkaline solutions, as the intestinal secretions. Used as an intestinal antiseptic, and antiphlogistic in doses of 10 to 30 grains (0.65 to 2 Gm.); also as an antiseptic dusting powder for wounds, etc.
Ichthargan, Silver Ichthyol	A compound containing about 30 per cent of metallic silver. It is used as a bactericide, astringent and antiphlogistic in gonorrhea

Unofficial Organic Compounds—*Continued*

Ichthoform (Ichthyol-formaldehyde)	A blackish-brown, insoluble powder, with little odor or taste. Used as an antiseptic, in surgical practice, for dusting on wounds, etc., and as an intestinal antiseptic. Dose, 15 to 30 grains (1 to 2 Gm.)
Iodo-gallicin (Bismuth oxyiodo-methyl-gallol)	Prepared by the action of bismuth oxyiodide on methylgallate. Used as a substitute for iodoform
Iodol, $C_4I_4.NH$ (U. S. P. VIII) (Tetraiodopyrrol)	In rhombic flakes. Melting at 114° C., and then volatilizing. Slightly soluble in cold water, readily soluble in alcohol Prepared by dissolving pyrrol and iodine in alcohol, allowing it to stand 24 hours and precipitating with water. It is used as an antiseptic dressing to wounds
Iodophenacetin (Iodophenine)	Prepared by adding some moderately diluted hydrochloric acid and a solution of potassium iodide and iodine in water to a solution of phenacetin in glacial acetic acid, when, upon cooling, steel-blue crystals are deposited. Contains about 50 per cent of iodine. Used externally
Iodopyrine, $C_{11}H_{11}IN_2O$	Prepared by mixing alcoholic solutions of iodine and antipyrine together and allowing to stand for several days, crystals separating out. It combines the physiological action of iodine and an antipyretic. Used in bronchial asthma and tertiary syphilis. Dose, 10 to 20 grains (0.65 to 1.3 Gm.)
Kryofin (Methylglycollicphenetidin)	Colorless crystals, soluble in alcohol, ether and chloroform
Lactophenin (Lactylparaphenetidin) $C_6H_4.OC_2H_5.N.H.CO.CH(OH).CH_3$	Prepared the same as acetphenetidin except that a lactic acid radical replaces the acetic acid radicle. Uses similar to acetphenetidin and in the same dose
Liantrol	An extract of coal tar used in the treatment of eczema in 10 per cent olive oil solution
Loretin (Meta-iodo-ortho-oxychinolin-ana-sulphonic Acid), $C_9H_4IOH—SO_3H—N$	A yellow, odorless powder; almost insoluble in water; and insoluble in ether and oils. Used as a dusting powder to replace iodoform and in 5 to 10 per cent ointments
Melubrin, N. N. R.	A white, odorless, almost tasteless powder, readily soluble in water. A powerful antipyretic in fever and an analgesic. Dose, 15 to 30 grains (1 to 2 Gm.) Manufactured by H. A. Metz Laboratories, Inc.
Menthiodol	Prepared by carefully heating 4 parts of menthol in a capsule, adding 1 part of finely powdered iodol, and triturating into a homogeneous mass. Used as a local application in neuralgia
Mesotan, $C_9H_{10}O_4$	Prepared by the action of chlormethyl ether on salicylates. A clear, yellowish, faintly aromatic liquid. Used, when diluted with olive oil, in treatment of rheumatism
Methacetin (Para-methoxyacetanilid) $C_6H_4(OCH_3).NHC_2H_3O$	Prepared like phenacetin except that methyl iodide or chloride is substituted for the respective ethyl compound. Lustrous, scaly, crystals; colorless, odorless. Antipyretic and analgesic in much smaller doses than phenacetin
Methylacetanilid, Exalgine $C_6H_5N(CH_3)CH_3CO$	Prepared by gradually adding acetyl chloride to monomethylanaline and crystallizing from boiling water. Colorless needles or prisms, inodorous and tasteless; freely soluble in alcohol, chloroform and boiling water. Employed as an analgesic. Dose, 3 to 10 grains (0.20 to 0.65 Gm.)
Methyl Acetate, $CH_3.C_2H_3O_2$	Prepared by processes similar to those employed for obtaining ethyl acetate, *quod vide*. It is present to some extent in crude wood naphtha. Sp. gr. 0.919. Readily soluble in water.
Methyl Alcohol	(See page 809)
Methyl Chloride, CH_3Cl	By distilling together a mixture of methyl alcohol, sodium chloride, and sulphuric acid. It is a gas at ordinary temperatures, but may be condensed by pressure to a colorless, very mobile liquid. It has an ethereal odor and a sweet taste. A local anesthetic
Methyl Iodide, CH_3I	By distilling 1 part phosphorus, 8 parts iodine, and 12 parts methyl alcohol, allowing the distillate to pass into a bottle containing water, then rectifying the product in a water bath over calcium chloride and lead oxide. A colorless liquid. Sp. gr. 2.23. Vesicant. It is best applied on lint
Methyl Amino-oxybenzoate (Orthoform-New) $C_6H_3.NH_2.OH.CO.O.(CH_3)$	Used as a local anesthetic, resembling cocaine in its action. Dose, 8 to 15 grains (0.5 to 1.0 Gm.)
Methylal (Methylene-dimethyl Ether) $CH_2(OCH_3)_2$	Prepared by distilling a mixture of methyl alcohol, sulphuric acid and manganese dioxide. A colorless liquid, easily soluble in water, in alcohol, in fatty and in ethereal oils. Used as a hypnotic. Dose, 75 to 100 grains (5.0 to 6.5 Gm.)
Methylene Dichloride (Dichloromethane, Bichloride of Methylene) CH_2Cl_2	A colorless liquid (sp. gr. 1.344), having an odor analogous to that of chloroform. Anesthetic. Given internally in the dose of 10 to 30 minims (0.6 to 2 cc.)
Methylenedicotoin, Fortoin $CH_2(C_{14}H_{11}O_4)_2$	A condensation product of cotoin and formaldehyde obtained by means of a dehydrating agent. Used as an antiseptic astringent in doses of 4 grains (0.25 Gm.) three times daily
Methyl-ethyl Ether, $CH_3C_2H_5O$	Prepared by the action of ethyl iodide upon sodium methylate. These substances are caused to react in a retort and passed through a solution of sodium hydroxide and cooled. Its use as an anesthetic is limited
Methylic Ether (Oxide of Methyl) $(CH_3)_2O$	Anesthetic
Migrainin Antipyrine-caffeine Citrate	Prepared by fusing on a water bath a mixture of 85 parts of antipyrine, 9 parts of caffeine and 6 parts of citric acid. A colorless, hygroscopic powder used in the treatment of headache in doses of from 5 to 15 grains (0.3 to 1 Gm.)
Monochlorphenol (Chlorphenol), $C_6H_4Cl.OH$	Germicide and antiseptic. Used by inhalation and as a local application

Unofficial Organic Compounds—*Continued*

Naftalan
An ointment-like body prepared by distilling a peculiar naphtha from the Caucasus district of Asia Minor, mixed with an anhydrous soap. It is used with good results in cases of burns and in various skin diseases

Naphthalene (U. S. P. VIII), $C_{10}H_8$
A distillation product from coal tar, purified by distillation. Colorless, shining, transparent laminæ. Used as an insecticide

Neuronal, Bromodiethylacetamide $C_6H_{13}BrNO$
A white, crystalline powder used as an effective hypnotic. Dose, 8 to 15 grains (0.5 to 1.0 Gm.)

Nirvanin $(OH)C_6H_3(COOCH_3)NH.CO.CH_2.N:(C_2H_5)_2.HCl$
Colorless, prismatic crystals, having about one-tenth the toxicity of cocaine while said to be equally effective

Nitrobenzene, Nitrobenzol, Oil of Mirbane $C_6H_5NO_2+H_2O$
A poisonous compound used in the perfuming of soap and in the manufacture of aniline

Nosophen (Iodophen, Tetra-iodophenolphthalein), $(C_6H_2I_2.OH)_2.C\begin{matrix}C_6H_4CO\\O\end{matrix}$
A yellow, odorless, tasteless powder, insoluble in water and alcohol. It contains about 60 per cent of iodine, and is used as an antiseptic dusting powder and as an intestinal antiseptic, in doses of 5 to 8 grains (0.32 to 0.5 Gm.)

Novaspirin, Methylenecitryl-salicylic acid, $C_{21}H_{16}O_{11}$
White, used in from 1 to 10 per cent solution in ophthalmology. Internally in doses of 5 to 8 grains (0.32 to 0.5 Gm.), odorless powder of slight acidulous taste. Used as a substitute for other salicylates, in doses of 24 to 30 grains (1.5 to 2 Gm.)

Oleum Succini Oil of Amber
Amber is a fossil resin of an extinct coniferous wood, found principally upon the Baltic coast. By destructive distillation an acid liquor containing succinic acid is produced, together with crude oil of amber; the latter is redistilled, and rectified oil of amber is the product. It is a pale, yellow liquid, having an empyreumatic odor and a warm, acrid taste. Sp. gr. 0.920. It is soluble in alcohol, and when mixed with fuming nitric acid acquires a red color, and is subsequently converted into a brown resinous mass known as *artificial musk*

Orcin, Dihydroxytoluene, $C_6H_3(CH_3)(OH_2)$
Antiseptic, antipyretic. Poisonous

Orexin, Phenyldihydrochinazolin Hydrochlorate, $C_6H_4\begin{matrix}CH_2N.C_6H_5\\N=CHCl\end{matrix}+2H_2O$
Stomachic. Dose, 4 to 7 grains (0.25 to 0.45 Gm.) two to three times a day

Orphol (Basic Betanaphthol Bismuth, Bismuth Naphtholate) $(C_{10}H_7O)_3Bi+3H_2O$
Fawn colored, almost odorless, and tasteless powder. It splits, in the intestines, into betanaphthol and bismuth. Used as an intestinal astringent and antiseptic in about 5- to 8-grain (0.32 to 0.5 Gm.) doses

Orthin, Orthohydrazin-paraoxybenzoate, $C_6H_3.OH.COOH.NH.NH_2$
A feeble antipyretic

Orthoform (Methyl-para-amido-meta-oxybenzoate), $C_6H_3(OH)(NH_2)COOCH_3$
Methyl ester of meta-amido-para-oxybenzoic acid. A white, odorless, tasteless powder, slightly soluble in water, soluble in alcohol or ether. It is used as an antiseptic and local anesthetic in wounds, ulcers, burns, etc., and as an intestinal antiseptic in doses of 8 to 15 grains (0.5 to 1 Gm.)

Orthoform-New (meta-amino-para-oxybenzoate of Methyl) $C_6H_3.NH_2.OH.CO.O.(CH_3)$
A local anesthetic resembling cocaine in action but not toxic. Used as a dusting powder, for insufflation, or as an ointment or oil solution

Oxychinaseptol (Diaphtherin), $C_6H_4(SO_2)\begin{matrix}O-NH.C_9H_6(OH)\\O-NH.C_9H_6(OH)\end{matrix}$
A powerful antiseptic

Pentane (Amylhydride), $CH_3.CH_2.CH_2.CH_2.CH_3$
A colorless, volatile liquid (sp. gr. 0.626), very inflammable.

Phenocoll Hydrochloride, (Amido-acetparaphenetidin Hydrochloride, Phenamin) $C_6H_4.OC_2H_5(NHCOCH_2NH_2).HCl$
Prepared by the action of chloracetylchloride on phenetidin and treating the product with ammonia; the basic substance is then neutralized with hydrochloric acid and the salt obtained in white, crystalline powder. Used as an antineuralgic and antipyretic. Dose, 5 to 15 grains (0.32 to 1.0 Gm.); in large doses is valuable in rheumatic fever

Phenolsulphonphthalein, $C_6H_4.SO_2.C.(C_6H_4OH_2).O$
Used as an indicator and a diagnostic reagent

Phenolsulphonic Acid, (Sulphocarbolic Acid, Sulphophenic Acid), $C_6H_6SO_4$
This substance is produced by the direct action of concentrated sulphuric acid upon phenol. It is soluble in water and in alcohol. The acid is a decided antiseptic, and its solutions coagulate albumin

Phenosal (Phenetidin Acetosalicylate)
Colorless crystals having an acidulous taste. Used as an antipyretic and antineuralgic in articular rheumatism and sciatica. Dose, 5 to 15 grains (0.32 to 1.0 Gm.)

Phenosalyl
A mixture composed of 9 parts of phenol, 1 part salicylic acid, 2 parts lactic acid, $\frac{1}{6}$ part menthol. Used as an antiseptic in conjunctivitis and in eczema

Phenylhydrazine, $C_6H_5.NH.NH_2$
Poisonous. Used as a test for sugar in urine (see Reagents, Chapter XCII)

Phloroglucol, Phloroglucin, $C_6H_3(OH)_3$
Use as an indicator (see Reagents, Chapter XCII)

Phthalic Acid, $C_8H_6O_4$
Produced by heating salicylic acid with a mixture of sulphuric acid and potassium ferrocyanide, and, when the reaction is ended, treating the resulting mass with ether, which extracts the phthalic acid. It occurs in nacreous laminæ or shining monoclinic prisms. Soluble in alcohol, ether, and benzene

Unofficial Organic Compounds—*Continued*

Piperazine (Diethylenediamine), $N_2\begin{cases}H_2\\(C_2H_4)_2\end{cases}$	Antirheumatic and solvent of uric acid. Dose, 15 grains (1 Gm.) during the day
Pneumin, Methylene Creosote	A yellow, odorless, tasteless powder obtained as a condensation product by the action of formaldehyde or creosote. Used in tuberculosis and in pulmonary catarrh. Dose, 8 grains (0.5 Gm.) four to five times daily
Potassium Sulphethylate, $KC_2H=SO_4$	By acting upon mercaptan with potassium. It is a dull white, granular mass, very soluble in water
Pyramidon, (Di-methyl-amido-phenyl-dimethyl-pyrazolon, Dimethylamido-antipyrine)	A yellowish-white, tasteless powder, similar to antipyrine in action, but milder, more gradual and lasting in its influence. Prepared by reducing an acetic acid solution of nitrosoantipyrine in alcohol to amido-antipyrine and treating with methyl chloride or iodide. An antipyretic and analgesic in treatment of rheumatism. Dose, 5 to 8 grains (0.32 to 0.5 Gm.)
Pyrantin, Phenosuccin, $C_6H_4(OC_2H_5)N{:}(COCH_2\text{-}CH_2\text{-}CO)$	Prepared by melting together *p*-amidophenol and succinic acid and crystallizing the product from alcohol or acetic acid solution. Colorless, prismatic needles. Its uses are similar to acetphenetidin; valuable in acute rheumatism. Dose, 15 to 45 grains (1 to 3 Gm.) per day
Pyridine, C_5H_5N	Remedy for asthma. Five to twenty drops in two ounces of water may be used in an atomizer, or five drops may be inhaled directly. Dose, six drops, gradually increased to twenty-five, daily
Pyrosal, Antipyrine Salicylacetate $C_9H_8O_5C_{11}H_{12}N_2O$	Occurs in colorless leaflets or needles. Used as an analgesic, antipyretic and antirheumatic. Dose, 5 to 10 grains (0.32 to 0.65 Gm.) several times daily
Rosolic Acid (Corallin)	Obtained by acting on commercial phenol with oxalic and sulphuric acids (see Reagents, Chapter XCII). Used as an indicator
Salacetol, Salantol, $C_6H_4(OH)CO_2CH_2COCH_3$	Fine white or slightly reddish crystalline needles, having a bitter taste. A germicide used in the treatment of dysentery and summer diarrhea. It is less poisonous than salol. Dose, adult, 20 to 40 grains (1.3 to 2.6 Gm.) and for children from 5 to 8 grains daily (0.32 to 0.5 Gm.)
Salicylamide, $C_6H_4\begin{cases}OH\\CONH_2\end{cases}$	Analgesic and antipyretic. Dose, 3 grains (0.2 Gm.)
Saliformin (Formin Salicylate Hexamethylenetetramine Salicylate, Urotropine Salicylate), $(CH_2)_6N_4.C_6H_4(OH)COOH$	A white powder, having a sour taste; soluble in alcohol and water. Used as a urinary antiseptic and as a solvent for uric acid deposits. Dose, 15 to 30 grains (1 to 2 Gm.)
Salitannol, $C_{14}H_{10}O_7$	A condensation product of salicylic and gallic acids, formed by the action of phosphorous oxychloride; white amorphous powder. It is employed as a safe surgical antiseptic because of its non-poisonous properties
Salipyrine, Antipyrine Salicylate, N. N. R. $C_{11}H_{12}ON_2.C_7H_6O_3$	Antipyretic, antirheumatic, antineuralgic. Dose, 7 to 15 grains (0.45 to 1 Gm.), in capsule or tablet
Salol Camphor, Camphol	A local anesthetic; a mixture of 3 parts of phenyl salicylate and 2 parts of camphor
Salophen, Acetylparamidophenyl-salicylate, $C_6H_4\begin{cases}OH\\COOC_6H_4.NH(C_2H_3O)\end{cases}$	Antirheumatic and intestinal antiseptic. Dose, 45 to 75 grains *during the day* (3 to 5 Gm.)
Saloquinine, Salochin	Prepared by heating a mixture of phenyl salicylate and anhydrous quinine in a vacuum. White, tasteless, odorless, crystalline, powder. Used in typhoid fever and neuralgia. Dose, 8 to 30 grains (0.5 to 2.0 Gm.) daily
Scarlet Red, Biebrich (Toluyl-azo-betanaphthol), $CH_3C_6H_4N:NC_6H_3(CH_3)N:N.C_{10}H_5.OH$	A dark brownish-red powder, practically insoluble in water, but soluble in oils, chloroform and phenol. Used in 4 to 8 per cent ointment in the treatment of burns, wounds, chronic ulcers, etc. (see also page 850)
Silver Sulphethylate, $AgC_2H_5SO_4$	By adding silver nitrate to an aqueous solution of mercaptan and collecting the white precipitate
Sodium Arsanilate, Atoxyl, $C_6H_4(NH_2)(AsO.OH.ON)+4H_2O$	Prepared by condensing aniline and arsenic acid, eliminating water, isolating the arsanilic acid and neutralizing with sodium carbonate. Used in treatment of syphilis, more toxic than salvarsan. Dose, 3 to 8 grains (0.2 to 0.5 Gm.)
Sodium Ethylate, C_2H_5NaO	By treating absolute alcohol with sodium. It crystallizes in broad laminæ. Used in 10 per cent solution in the treatment of skin diseases
Somnal, $C_7H_{12}Cl_3O_3N$	A compound of chloral, alcohol, and urethane forming a clear, colorless liquid of a burning taste. Used as a hypnotic. Dose, from ½ to 1 drachm (2 to 4 Gm.)
Sozal (Aluminum Paraphenol-sulphonate), $(C_6H_4(OH)SO_3)_3Al$	Antiseptic. Used in a 1 per cent solution as a wash
Soziodol (Diiodparaphenol-sulphonic Acid), $C_6H_2I_2(SO_3H)OH$	Bactericide. Used as a dusting powder and as a wash in 3 per cent solution
Sozolic Acid (Orthophenolsulphonic Acid), $C_6H_4(HSO_3)OH$	Antiseptic. A 33⅓ per cent solution is called *aseptol*
Styptol, Cotarnine Phthalate $(C_{12}H_{13}O_3N)_2C_6H_4(COOH)_2$	Used internally as a special uterine vessel constrictor. Locally as a dusting powder. Dose, ¾ of a grain (0.048 Gm.)
Subcutin, $C_2H_5COO.C_6H_4.NH_2.SO_3H.C_6H_4OH$	A white, crystalline powder used as a local anesthetic, non-toxic and distinctly germicidal

Unofficial Organic Compounds—*Continued*

Sublamine, Mercuryethylenediamine sulphate, $HgSO_4.2C_2H_4(NH_2)_2 + 2H_2O$	A non-irritating, penetrating, readily soluble disinfectant. Used in hand disinfection in solutions of 1 to 1000 to 1 to 2000
Succinic Acid, $C_4H_6O_4$	Used with advantage in delirium tremens
Succinyl, Disalicylic Acid Diaspirin, $C_{18}H_{14}O_8$	White, crystalline powder, almost tasteless and without odor. Forms salts with inorganic and organic bases. Uses similar to those of salicylic acid. Dose, 15 grains (1 Gm.) three to four times daily.
Sulphaminol (Thioxydiphenylamine), $C_{12}H_9S_2NO$	Used as a substitute for iodoform. The dose is 4 grains (0.25 Gm.). Externally, it may be used in powder or in oily mixtures
Sulphanilic Acid, 1 : 4 Para-amino-benzene-sulphonic Acid	Produced by the action of strong sulphuric acid on colorless analine. Used in the dye industry and also in diazo test solution (see Reagents, Chapter XCII)
Tannoform (Methyleneditannin), $CH_2(C_{14}H_9O_9)_2$	Prepared by mixing solutions of formaldehyde and tannic acid, precipitating with concentrated hydrochloric acid, washing and drying. Used as an astringent dusting powder in cases of excessive sweating
Tetronal, $(C_2H_5)_2.C.(SO_2C_2H_5)_2$	Sedative hypnotic. Dose, 15 to 30 grains (1 to 2 Gm.)
Thermodin, Phenacetin Urethrane, $C_6H_4(OC_2H_5).N(COOC_2H_5)(CH_3CO)$	A compound of acetphenetidin and ethyl carbamate. Used as an analgesic, antipyretic and antiseptic, in typhoid fever, pneumonia, etc. Dose, 5 to 10 grains (0.32 to 0.65 Gm.)
Thiocol (Potassium Guaiacol Sulphonate)	A fine, white powder, soluble in water, and containing about 60 per cent of guaiacol. Antitubercular and anticatarrhal. Dose, 5 to 20 grains (0.32 to 1.3 Gm.)
Thymacetin $C_6H_2.CH_3.C_3H_7(OC_2H_5).NH(C_2H_3O)$	Prepared from thymol in a manner similar to that of phenacetin from phenol. White, crystalline powder. Used as an analgesic in doses of from 3 to 15 grains (0.2 to 1 Gm.)
Tribromphenol, $C_6H_2Br_3.OH$ Bromol	Antiseptic
Trichlorphenol, $C_6H_2Cl_3OH$ Omal	Used in erysipelas, in the form of a glycerite containing 5 to 10 per cent, applied to the parts twice daily
Triphenin, (Propionyl-phenetidin) $C_6H_4.C_2H_5O.NH.(CH_3.CH_2.CO)$	Prepared by heating *p*-phenetidin with propionic acid. Colorless, odorless and slightly bitter crystals. Soluble in about 2000 parts of water. An antipyretic and analgesic. Similar in action to phenacetin. Dose, 8 to 15 grains (0.5 to 1 Gm.)
Tropæolin	Dye-color used as an indicator in volumetric analysis
Tumenol	Used as a local application in eczema, in a 10 per cent solution
Tussol (Antipyrine Phenylglycolate, Antipyrine Mandelate), $C_{11}H_{12}ON_2.C_6H_5CH(OH)COOH$	This salt is said to be superior to antipyrine in the treatment of whooping cough. Dose, ¾ to 6 grains (0.045 to 0.4 Gm.), according to age
Urasol, Afsol (Acetyl-methylene-disalicylic Acid), $CH_2(C_6H_3.OC_2H_3O.COOH)_2$	Used in the treatment of muscular rheumatism and gout. Dose, 5 to 8 grains (0.32 to 0.5 Gm.)
Valeridin, Valerydin, Sedatin (Iso-valeryl-*p*-phenetidin) $C_6H_4.NHCOC_4H_9.OC_2H_5$	Prepared by heating *p*-phenetidin with valeric acid. White glistening needles almost insoluble in water but soluble in alcohol. Used in migraine, neuralgia and hysteria in dose of 8 to 15 grains (0.5 to 1 Gm.)
Valyl (Valeryldiethylamide) $C_4H_9CON(C_2H_5)_2$	Prepared by the interaction of valeric acid and diethylamine. Used as a sedative and antispasmodic in hysteria. Dose, 2 grains (0.13 Gm.) in capsules
Xeroform (Tribromphenol Bismuth, Tribromocarbolate of Bismuth), $(C_6H_2Br_3O)_2BiOH + Bi_2O_3$	A yellowish-green, insoluble powder, containing about 50 per cent of tribromphenol and about 50 per cent of Bi_2O_3. Used as an intestinal antiseptic in doses of 8 to 15 grains (0.5 to 1 Gm.). Also used as a dusting powder on fresh and infected wounds
Xylol (Xylene), C_8H_{10}	By treating the oily liquid separating from diluted crude wood spirit and from the light oil of wood tar or coal tar, first with sulphuric acid, and afterwards subjecting these liquids to fractional distillation, collecting only that portion which distils between 136° and 140° C. (276.8° and 284° F.). A thin, colorless liquid, resembling benzene. It has a burning taste. Soluble in alcohol. Dose, 20 to 30 minims (1.2 to 2 cc.)

CHAPTER LXVI

PRODUCTS OF THE ACTION OF FERMENTS UPON ACID SACCHARINE FRUITS

THE acid saccharine fruits form an important class in medicine and pharmacy. Their characteristic constituent is usually a vegetable acid (in some fruits several acids are found); sugar and albuminous principles are present in small amount, and, on account of the presence of sugar, vinous fermentation may be induced in these juices, resulting in the production of the alcoholic beverages known as wines, which upon distillation yield brandies. The fruits of this class which contribute the most useful products to pharmacy are grapes, lemons, limes, oranges, apples, tamarinds, raspberries, pineapples, strawberries, currants, blackberries, etc. Most of the juices of these fruits readily undergo fermentation. The clear alcoholic liquid left after decomposition has received various names, according to the fruit from which it is derived, *viz.*, wine from grapes, cider from apples, perry from pears, etc.

The products of the grape will be considered first.

Wines—There are no medicated wines now official, the Brussels Conference of 1902 having advised against their continued recognition because of the lack of uniformity in commercial wines which were used in their preparation. The Pharmacopœia dismissed all wines from the Ninth Revision, but the N.F. continued a number of the formulas for a decade. These have now been discarded. Plain wines were not admitted to the U. S. P. X and their purchase and sale are exclusively under the regulations of the Volstead Act as administered by the Internal Revenue Department (see page 1261).

Unofficial Fermentation Products

VINUM ALBUM.—White Wine

An alcoholic liquid made by fermenting the juice of fresh grapes, the fruit of *Vitis vinifera* Linné (Fam. *Vitaceæ*), freed from seeds, stems, and skins, and subjected to the usual cellar-treatment for fining and aging.

When White Wine is prescribed without further specification, it is recommended that a dry White Wine of domestic production be employed.

White Wine should be preserved in well-closed casks, filled as full as possible, or in well-stoppered bottles, in a cool place.

VINUM RUBRUM.—Red Wine

An alcoholic liquid made by fermenting the juice of fresh red-colored grapes, the fruit of *Vitis vinifera* Linné (Fam. *Vitaceæ*) in presence of their skins, and subjected to the usual cellar-treatment for fining and aging.

When Red Wine is prescribed without further specification it is recommended that a dry Red Wine of domestic production be employed.

Red Wine should be preserved in well-closed casks, filled as full as possible, or in well-stoppered bottles, in a cool place.

VINUM XERICUM. N. F. IV. Sherry Wine

An alcoholic liquid made by fermenting the juice of fresh ripe grapes, the fruit of cultivated species of *Vitis* Linné (Fam. *Vitaceæ*), freed from seeds, stems and skins, and fortifying with pure grape brandy. It contains not less than 16 per cent nor more than 24 per cent of C_2H_5OH, by volume. Preserve it in well-closed casks or in well-stoppered bottles, in a cool place.

Official Description—A pale yellowish-brown or amber-colored liquid.

Odor and Taste—It has a pleasant, aromatic odor, free from yeastiness, and a fruity, characteristic taste, without excessive sweetness or acidity.

Specific gravity: from 0.985 to 1.000 at 25° C.

Tests for Identity and Impurities—Evaporate 100 cc. of Sherry Wine in a tared dish, on a water bath, and dry the residue to constant weight at 100° C. (212° F.): it weighs not less than 3 Gm. nor more than 7 Gm. Ignite this residue at a low temperature and burn it gradually to whiteness, moisten the ash with a small portion of ammonium carbonate T.S. and again carefully ignite; the ash weighs not less than 0.175 Gm. nor more than 0.5 Gm.

Free Acid—Dilute 50 cc. of Sherry Wine with 200 cc. of distilled water; it requires for neutralization not less than 20 cc. nor more than 40 cc. of tenth-normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator.

Sulphate—Acidulate 50 cc. of Sherry Wine with hydrochloric acid, heat, and add an excess of barium chloride T.S. Collect the precipitate on a filter of known ash content, wash it thoroughly, dry and ignite: the residue weighs not more than 0.034 Gm.

Tannic Acid—To 10 cc. of Sherry Wine add an equal volume of distilled water and five drops of ferric chloride T.S.: not more than a faint greenish-brown color appears.

Saccharin—Add 10 cc. of diluted sulphuric acid to 75 cc. of Sherry Wine and shake out the mixture in a separator twice, using each time 20 cc. of a mixture of equal volumes of purified petroleum benzin and ether. Transfer the separated benzin-ether solution to an evaporating dish, allow the solvent to evaporate spontaneously and dissolve the residue in 3 cc. of distilled water; the solution does not have a sweet taste.

Salicylic Acid—nor does this solution from the saccharin test yield a violet color upon the addition of a few drops of a dilute solution of ferric chloride (1 in 200).

SPIRITUS VINI VITIS. U.S. Brandy

Brandy is official in the U.S.P.X, but its legal purchase and sale are exclusively under the regulations of the Volstead Act as administered by the Internal Revenue Department of the United States (see page 1261). The official description will be found on page 916.

ACIDUM TARTARICUM. U.S. Tartaric Acid

[Acid. Tart.]

Tartaric Acid contains not less than 99.5 per cent of $C_2H_2(OH)_2(COOH)_2$ (150.07).

Preparation—This important acid may be prepared by saturating the excess of acid in acid potassium tartrate or cream of tartar with calcium carbonate, and decomposing the resulting insoluble calcium tartrate by sulphuric acid, which precipitates in combination with the lime as calcium sulphate, and liberates the tartaric acid. The process, when thus conducted, furnishes only one-half of the tartaric acid. The other half may be procured by decomposing the neutral potassium tartrate remaining in the solution after the precipitation of the calcium tartrate by calcium chloride in excess. By double decomposition potassium chloride will be formed in solution, and a second portion of calcium tartrate will precipitate, which may be decomposed by sulphuric acid, together with the first portion.

$$\underset{\text{acid potassium tartrate}}{2KHC_4H_4O_6} + \underset{\text{calcium carbonate}}{CaCO_3} = \underset{\text{potassium tartrate}}{K_2C_4H_4O_6} + \underset{\text{calcium tartrate}}{CaC_4H_4O_6} + \underset{\text{water}}{H_2O} + \underset{\text{carbon dioxide}}{CO_2}$$

then

$$\underset{\text{potassium tartrate}}{K_2C_4H_4O_6} + \underset{\text{calcium chloride}}{CaCl_2} = \underset{\text{calcium tartrate}}{CaC_4H_4O_6} + \underset{\text{potassium chloride}}{2KCl}$$

and

$$\underset{\text{calcium tartrate}}{2CaC_4H_4O_6} + \underset{\text{sulphuric acid}}{2H_2SO_4} = \underset{\text{calcium sulphate}}{2CaSO_4} + \underset{\text{tartaric acid}}{2H_2C_4H_4O_6}$$

Calcium sulphate is sometimes substituted for calcium chloride in the second stage of the decomposition. Tartaric acid is a dibasic acid; one or two of its hydrogen atoms are capable of being replaced by metals. With monad metals, acid, neutral, and double tartrates may be formed, thus:

$H_2C_4H_4O_6$	$HKC_4H_4O_6$	$K_2C_4H_4O_6$	$KNaC_4H_4O_6$
tartaric acid	acid potassium tartrate	neutral potassium tartrate	potassio-sodium tartrate

Tartaric acid contains no water of crystallization. The tartrates are important salts. Three are official, two of them being double salts, *viz.*, antimony and potassium tartrate, potassium and sodium tartrate; the other salt is potassium bitartrate.

Tests for Tartrates

Tartrates—With neutral solutions of tartrates, silver nitrate T.S. produces a white precipitate. Upon dissolving this precipitate in just sufficient ammonia T.S. and warming, metallic silver is deposited on the sides of the test tube,

forming a mirror. When a drop of ferrous sulphate T.S., then a few drops of hydrogen dioxide T.S., and finally an excess of sodium hydroxide T.S. are added to a solution of tartaric acid or of a tartrate, acidified with acetic acid, a purple or violet color is produced.

Description and Physical Properties—Colorless, translucent crystals, or a white, granular or fine powder. It is odorless, has an acid taste, and is stable in the air.

One Gm. of Tartaric Acid is soluble in 0.75 cc. of water and in 3 cc. of alcohol, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water. The Acid is almost insoluble in chloroform and only slightly soluble in ether.

Tests for Identity—When slowly ignited, Tartaric Acid gradually decomposes, emitting an odor resembling that of burning sugar (*difference from citric acid*).

An aqueous solution of Tartaric Acid is acid to litmus paper and responds to the reactions for tartrates, page 942.

Tests for Purity—Ash: not more than 0.05 per cent.

Nearly neutralize 10 cc. of an aqueous solution of the Acid (1 in 10) with ammonia T.S. and add 10 cc. of calcium sulphate T.S.: no turbidity is produced (*oxalate*).

The addition of 1 cc. of barium chloride T.S. to 10 cc. of an aqueous solution of the Acid (1 in 100) to which 3 drops of hydrochloric acid have previously been added, causes no turbidity (*sulphate*).

A 10 cc. portion of an aqueous solution of the Acid (1 in 50) mixed with 0.5 cc. of hydrochloric acid meets the requirements of the test for *heavy metals*, page 1519.

Dissolve 10 Gm. of Tartaric Acid in 20 cc. of distilled water, add 2 cc. of sulphurous acid T.S., and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 cc. of sodium cyanide T.S., and follow this immediately with stronger ammonia water until the precipitate formed is redissolved and the solution has a slight odor of ammonia. Cool, transfer the solution to a 50 cc. graduated cylinder, dilute with sufficient distilled water to measure 50 cc. and add 3 drops of sodium sulphide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface, is not darker than the color of a control solution prepared as follows: Dissolve 2 Gm. of reagent ammonium chloride (page 1529) in 20 cc. of distilled water, add 4 cc. of a solution containing 0.08 Gm. of lead nitrate in 1000 cc. of distilled water, and 1 cc. of diluted hydrochloric acid. Treat this solution with the same quantity of sulphurous acid, sodium cyanide T.S. and stronger ammonia water, as directed above; Transfer the mixture to another 50 cc. cylinder, dilute it with sufficient distilled water to make 50 cc., and add 3 drops of sodium sulphide T.S. Before adding the sodium sulphide T.S., the liquid must possess a distinct odor of ammonia. The two cylinders used must be matched, be of practically colorless glass, and have the same internal diameter (*lead*).

Assay—Proceed as directed under the assay for acids, page 1514, using about 3 Gm. of Tartaric Acid and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.07504 Gm. of $C_2H_2(OH)_2(COOH)_2$.

This assay is explained on page 1453.

U. S. P. Preparations—Acidum Hydriodicum Dilutum; Potassii Citras Effervescens; Pulvis Effervescens Compositus; Sodii Phosphas Effervescens.

N. F. Preparations—Elixir Pepsini, Bismuthi et Strychninæ; Extractum Hydrastis; Glyceritum Bismuthi; Sal Carolinum Factitium Effervescens; Sal Kissingense Factitium Effervescens; Sal Lithii Citras Effervescens; Sal Magnesii Sulphatis Effervescens; Sal Potassii Bromidi Effervescens Compositus; Sal Vichyanum Factitium Effervescens.

History—This organic acid was discovered about 1776 by Scheele, the famous Swedish apothecary, while investigating cream of tartar which had been known for many centuries.

The list of preparations into which tartaric acid enters officially is given above. It is chiefly used as the acid ingredient of preparations in which it is neutralized by a bicarbonate, as in effervescent salts, and the free acid will not be found in the finished product.

ACIDUM CITRICUM. U. S. Citric Acid

[Acid. Cit.]

Citric Acid contains not less than 99.5 per cent of $C_3H_4(OH)(COOH)_3$ (210.11) H_2O.

Preparation—Although this acid is found in many plants, it is obtained upon a commercial scale from the juice of limes and lemons. It is prepared from *lime juice* (see page 947) by a very simple process, but one requiring some careful manipulation. The boiling juice is first completely saturated with calcium carbonate (chalk or whiting) in fine powder, and the calcium citrate

formed is allowed to subside. This is then washed repeatedly with water, and is decomposed by diluted sulphuric acid. An insoluble calcium sulphate is precipitated, and the disengaged citric acid remains in solution. This is carefully concentrated in leaden boilers until a pellicle begins to form, when it is transferred to other vessels to cool and crystallize.

$$\underset{\text{citric acid}}{2H_3C_6H_5O_7} + \underset{\substack{\text{calcium}\\\text{carbonate}}}{3CaCO_3} = \underset{\text{calcium citrate}}{Ca_3 2C_6H_5O_7} + \underset{\text{water}}{3H_2O} + \underset{\substack{\text{carbon}\\\text{dioxide}}}{3CO_2}$$

$$\underset{\text{calcium citrate}}{Ca_3 2C_6H_5O_7} + \underset{\text{sulphuric acid}}{3H_2SO_4} = \underset{\text{citric acid}}{2H_3C_6H_5O_7} + \underset{\text{calcium sulphate}}{3CaSO_4}$$

Citric acid contains one molecule of water of crystallization; it differs in this respect from tartaric acid, which contains none. The presence of this molecule of water of crystallization makes it valuable in the preparation of granular effervescent salts. It is a tribasic acid; in other words, three atoms of hydrogen are replaceable by metals, three classes of citrates being formed according as one, two, or three hydrogen atoms are replaced.

The citrates are a valuable class of medicinal salts, nine being official—five are simple salts: ferric, bismuth, lithium, potassium and sodium citrates, one granular effervescent: effervescent potassium citrate; three are double salts: bismuth and ammonium citrate, iron and ammonium citrate, iron and quinine citrate. A number of these are not true chemical compounds based upon molecular proportions, but are pharmaceutical preparations based upon the respective dosages of the constituents. Citric acid is used in two solutions —solution of magnesium citrate, and solution of potassium citrate. The numerous other official preparations into which it enters will be found below.

Tests for Citrates

Citrates—Neutral solutions of citrates are not affected in the cold by the addition of an excess of calcium chloride T.S., but, upon heating the mixture, a white precipitate is produced. When to a hot solution of a citrate, to which has been added one-tenth of its volume of mercuric sulphate T.S., potassium permanganate is added, a white precipitate is produced.

Description and Physical Properties—Colorless, translucent crystals, or a white powder. It is odorless, has an acid taste, and is efflorescent in warm air.

One Gm. of Citric Acid is soluble in 0.5 cc. of water, 1.8 cc. of alcohol, and in about 30 cc. of ether, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water.

Tests for Identity—An aqueous solution of Citric Acid is acid to litmus paper and responds to the reactions for citrates, page 944.

When slowly ignited, Citric Acid is gradually decomposed without emitting an odor resembling that of burning sugar (*difference from tartaric acid*).

Tests for Purity—Ash: not more than 0.05 per cent.

Neutralize 10 cc. of an aqueous solution of the Acid (1 in 10) with ammonia T.S., add 5 drops of diluted hydrochloric acid, cool, and add 2 cc. of calcium chloride T.S.: no turbidity is produced, (*oxalic acid*).

The addition of 1 cc. of barium chloride T.S. to 10 cc. of an aqueous solution of the Acid (1 in 100), to which 3 drops of hydrochloric acid have previously been added, causes no turbidity (*sulphate*).

Mix 1 Gm. of powdered Citric Acid with 10 cc. of sulphuric acid in a test tube previously rinsed with sulphuric acid, and maintain the temperature of the mixture at 90° C. for one hour: no color darker than yellow develops (*tartaric acid*).

Ten cc. of an aqueous solution of the Acid (1 in 50) mixed with 0.5 cc. of hydrochloric acid meets the requirements of the test for *heavy metals*, page 1519.

Dissolve 10 Gm. of Citric Acid in 20 cc. of distilled water, add 2 cc. of sulphurous acid T.S., and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 cc. of sodium cyanide T.S., and follow this immediately with stronger ammonia water until the solution possesses a slight odor of ammonia. Cool, transfer the solution to a 50 cc. graduated cylinder, dilute with sufficient distilled water to measure 50 cc., and add 3 drops of sodium

sulphide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface is not darker than the color of a control solution prepared as follows: dissolve 2 Gm. of reagent ammonium chloride in 20 cc. of distilled water, add 4 cc. of a solution containing 0.08 Gm. of lead nitrate in 1000 cc. of distilled water, and 1 cc. of diluted hydrochloric acid. Treat this solution with the same quantity of sulphurous acid, sodium cyanide T.S. and stronger ammonia water, as directed above; transfer the mixture to another 50 cc. cylinder, dilute it with sufficient distilled water to make 50 cc., and add 3 drops of sodium sulphide T.S. Before adding the sodium sulphide T.S. the liquid must possess a distinct odor of ammonia. The two cylinders used must be matched, be of practically colorless glass, and have the same internal diameter (*lead*).

Assay—Proceed as directed under the assay for acids, page 1514, using about 3 Gm. of Citric Acid and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.07004 Gm. of $C_3H_4(OH)(COOH)_3.H_2O$.

This assay is explained on page 1453.

U. S. P. Preparations—Liquor Magnesii Citratis; Liquor Potassii Citratis; Potassii Citras Effervescens; Sodii Phosphas Effervescens; Syrupus Acidi Citrici; Syrupus Aurantii.

N. F. Preparations—Elixir Ferri Pyrophosphatis, Quininæ et Strychninæ; Liquor Ferri Citratis; Liquor Ferri Salicylatis; Liquor Phosphatum Compositus; Liquor Sodii Citratis; Liquor Sodii Phosphatis Compositus; Sal Carolinum Factitium Effervescens; Sal Kissingense Factitium Effervescens; Sal Lithii Citratis Effervescens; Sal Potassii Bromidi Effervescens Compositus; Sal Vichyanum Factitium Effervescens.

Uses—Citric acid in solution is often used as a substitute for lemon juice. It is sometimes called "*salt of lemon*" which has led to confusion with some of the oxalates which are also called by that name. When any inquiry is made for salt of lemon, its proposed use should be carefully investigated and in dispensing it the true name also should be placed upon the label.

Citric acid is also known by the synonym "*sour salt*", and is sold in small cartons bearing that label for use by Jewish cooks in preparing certain sour dishes. The dose is from five to thirty grains (0.3 to 2 Gm.). It is rarely given in its free state, but is largely used in combination and in many solutions and syrups, and in making effervescent salts. Its aqueous solution, even when concentrated, is not very stable, as it develops fungoid growths.

Acid Saccharine Fruits Containing Pectinous Bodies

The pulpy constituents of fruits and fleshy roots undergo naturally certain changes when subjected to the influences of a ferment known as *pectase*. These changes can be closely imitated artificially when the pulp is treated with acids or alkalies in aqueous solution, by the aid of heat. According to Fremy, pectase exists in fruits in either a soluble or an insoluble condition. Green, unripe fruits contain *pectose*, a substance which is supposed to be isomeric with cellulose and which gives to such fruits their hardness. Pectose is insoluble in water, alcohol, or ether.

In the process of ripening fruits, the pectase slowly acts on the pectose, the hardness disappears, *pectin* is formed, and the fruit is soft and ripe. When it is overripe, *parapectin* and *metapectic acid* are produced. The moderate action of heat and water upon fruits is thus explained. The citric, tartaric, or malic acid in the fruit acts on the pectose, softening it, and converting it into pectin, and the pectin is then acted upon by the ferment pectase, which causes it to gelatinize, on cooling, through the production of pectosic acid. This is the cause of the formation of fruit jellies. The rapid application of strong heat to the pulp of fruits results in the coagulation and destruction of the ferment pectase, and the production of jelly is thus prevented.

Alkalies form soluble compounds with pectosic acid and pectin, and hence, when gelatinous precipitates are found in fluidextracts and tinctures, due to the formation of either of these substances, they may be dissolved by the application of an alkaline solution. The use of solution of potassium hydroxide in fluidextract of senega is an illustration of this.

Fruit Juices—These are largely used for flavoring syrups, and for use in dispensing soda water. They are made by expressing the juice from fresh fruits and bottling as directed in the chapter on syrups (see page 262). They are often clarified by separating the albuminous and pectinous substances by a slight degree of fermentation.

There is but one fruit belonging to this class, the raspberry, official in the N. F. This is used in preparing a syrup of raspberry which is offered as a type process for other fruit syrups (see page 282).

RHUS GLABRA. U.S. Rhus Glabra

[Rhus Glab.—Sumac Berries]

Rhus Glabra is the dried ripe fruit of *Rhus glabra* Linné (Fam. *Anacardiaceæ*). Rhus Glabra contains not more than 5 per cent of stems or other foreign organic matter.

This fruit owes its acidity to malic acid, which exists in it as calcium and potassium malate. This acid is found in unripe apples and in a great number of fruits, roots, leaves, stems, etc. Rhus glabra also contains tannin, gallic acid, and red coloring matter.

Malic acid may be obtained from rhus glabra by exhausting the berries with water, evaporating, filtering, and crystallizing the acid calcium malate, which is then dissolved in boiling water, and treated with lead acetate, when lead malate is precipitated; this is then suspended in water, hydrogen sulphide is passed through it, lead sulphide is precipitated, and the solution of malic acid is evaporated to permit crystallization. Malic acid is found in colorless, shining needles having a sour taste and an acid reaction. It is soluble in alcohol and is deliquescent in the air. It is dibasic.

For the microscopic description see the U. S. P. X.

Description and Physical Properties—Flattened ovoid, nearly globular or somewhat reniform, from 3.5 to 5.5 mm. in length, nearly as broad, but usually somewhat less in thickness; a raised scar at the apex and the five-parted calyx occasionally with a short pedicle at the base; externally dark red, velvety with short hairs; endocarp smooth, shiny, crimson to yellowish-red; 1-locular, 1-seeded; seed brown, very hard; inodorous; taste acidulous and astringent.

U. S. P. Preparation—Fluidextractum Rhois Glabræ.

Uses—Rhus Glabra is a useful astringent, chiefly employed as a gargle and sometimes given for diarrhea. The dose is fifteen grains to one drachm (1 to 4 Gm.).

RUBI IDÆÆ FRUCTUS. N.F. Raspberry

[Rub. Id. Fruct.—Red Raspberries]

Raspberry is the fresh, ripe fruit of varieties of *Rubus Idæus* Linné or of *Rubus strigosus* Michaux (Fam. *Rosaceæ*).

Description and Physical Properties—An aggregate fruit, globular or hemispherical with a concave depression at the base where separated from the receptacle, composed of twenty or more small, rounded-polygonal, succulent drupelets; pericarps externally red, non-globular hairs numerous up to 0.640 mm. in length; mesocarps fleshy, juice red; parenchyma with rosettes of calcium oxalate up to 0.035 mm. in diameter; endocarps small stones with wrinkled surfaces. Odor characteristic, aromatic, taste pleasant, sweet, acidulous.

For pharmaceutical purposes, Black Raspberries, the fresh ripe fruit of varieties of *Rubus occidentalis* Linné (Fam. *Rosaceæ*) may be substituted either in part or wholly for Red Raspberries.

N. F. Preparations—Syrupus Rubi Idæi; Elixir Gentianæ Glycerinatum.

Uses—The fruit is used only for the preparation of an agreeably flavored syrup.

SUCCUS POMORUM. N.F. Fresh Apple Juice

[Suc. Pomor.—Cider]

The freshly expressed juice of sound ripe, sour apples, the fruit of cultivated varieties of *Pyrus Malus* Linné (Fam. *Rosaceæ*).

N. F. Preparation—Extractum Ferri Pomatum.

Uses—Apple juice contains *malic acid* and is used in the preparation of crude iron malate (see page 466). It must be promptly used or else preserved by sterilization as it readily undergoes alcoholic fermentation.

TAMARINDUS. N.F. Tamarind

Tamarind is the partially dried ripe fruit of *Tamarindus indica* Linné (Fam. *Leguminosæ*), deprived of the brittle outer portion of the pericarp and preserved in sugar or syrup.

Tamarind contains not more than 2 per cent of organic matter.

Description and Physical Properties—A pulpy mass of light reddish-brown color, changing with age to a dark brown, containing some branching fibers and numerous reddish-brown, smooth, oblong or quadrangular, compressed seeds, each enclosed in a tough membrane; the pulp with parenchyma cells containing a few starch grains up to 0.020 mm. in diameter, calcium oxalate in rosettes up to 0.100 mm. in diameter, and crystal fibers with prisms of calcium oxalate up to 0.050 mm. in length. Odor distinct; taste sweet and agreeably acid.

Preparation—Confectio Sennæ.

Uses—It is purgative, and is often used to make laxative confections. The dose is 4 drachms (16 Gm.).

Unofficial Fruits

Apple	The fruit of *Pyrus Malus*. The constituents are 7 to 10 per cent sugar, ½ to 1 per cent free acid, and 5 per cent each albuminous and pectinous substances. The fermented juice of the apple is termed *cider* or *vinegar*
Apricot	The fruit of *Prunus Armeniaca*. The average constituents are 1 to 2 per cent sugar, ½ to 1 per cent free acid, ½ to 1 per cent albuminous substances, and 5 to 10 per cent pectinous substances
Banana	The fruit of *Musa sapientum* and other species. The average composition is water 75.3, protein 1.3, fat 0.6, sugar 15, starch 5
Blackberry (Rubi Fructus, N. F. IV)	The fresh, ripe fruit of varieties of *Rubus nigrobaccus* Bailey or *Rubus villosus* Aiton (Fam. *Rosaceæ*). An aggregate fruit, ovate to oblong, rounded or slightly pointed, composed of numerous, shining black drupelets attached to an esculent receptacle; pericarp externally smooth or with only a few hairs (*R. villosus*), mesocarps fleshy, juice purple-red, endocarps hard, black surfaces deeply wrinkled It is used as a flavoring agent, chiefly in remedies for diarrhea such as *Blackberry Cordial*
Cherry	The fruit of a species of *Prunus*. The average constituents are 8 to 13 per cent sugar, 1 per cent free acid, and ½ to 3 per cent each albuminous and pectinous substances
Cranberry	The bright red, acid berry produced by an ericaceous plant of the genus *Oxycoccus*. It is much used for making sauce, jelly tarts, etc.
Currant	The fruit of *Ribes rubrum*. The average constituents are 4 to 7 per cent sugar, 1 to 2 per cent free acid, ¼ to ½ per cent albuminous substances, and ⅛ per cent pectinous substances
Figs	The oblong or nearly globose fruit of the fig tree (*Ficus carica*). The fruit is pulpy when ripe, and is eaten raw, or preserved, or dried with sugar, in which form it is generally known
Gooseberry	The fruit of *Ribes Grossularia*. The average constituents are 6 to 8 per cent sugar, 1 to 1½ per cent free acid (chiefly citric), ½ per cent albuminous substances, and ½ to 2 per cent pectinous substances
Huckleberry	The edible black or dark blue berry of any species of *Gaylussacia*, the common market variety being *G. resinosa*. This name is frequently applied to the *Blueberry* which is a species of *Vaccinium* and contains numerous minute seeds, while the huckleberry contains ten nutlets
Lemon Juice (Limonis Succus)	The freshly expressed juice of the ripe fruit of *Citrus Limonum* Risso (Fam. *Rutaceæ*), a slightly turbid, yellowish liquid. Used as an antiscorbutic and also in the preparation of true *neutral mixture* and for the making of lemon syrup
Lime Juice (Succus Citri, N. F. IV)	The expressed juice of the ripe fruit of *Citrus medica acida* (Roxburgh) Bonavia (Fam. *Rutaceæ*), containing in each 100 cc. not less than 5 Gm. nor more than 10 Gm. of total acids, calculated as crystallized citric acid A clear or slightly turbid, pale yellow or yellowish-green liquid, having the characteristic odor and taste of limes. It is used as a pleasant flavor and vehicle. For test for purity see the N. F. IV
Orange	The large globose fruit of the rutaceous tree *Citrus Aurantium*. The orange botanically is a berry, consisting of ten or more separable pulpy carpels, each containing several seeds. These are covered by a yellowish, leathery rind containing many oil glands. The juice contains citric acid and some sugar
Peach	The fruit of *Amygdalus Persica*. The average constituents are 1½ per cent sugar, ½ per cent free acid, ½ per cent albuminous substances, and 6 per cent pectinous substances
Pear	The fruit of *Pyrus communis*. The average constituents are 7 per cent sugar, 1 per cent free acid, ¼ per cent albuminous substances, and 3 per cent pectinous substances
Pineapple	The fruit of *Ananas sativa*. The juice contains 2 per cent sugar, 1 per cent free acid, and 3 per cent albuminous and pectinous substances
Plum	The fruit tree belonging to the genus *Prunus*. The average constituents are about 1 to 2 per cent sugar, ½ to 1 per cent free acid, ½ per cent albuminous substances, and 2 to 11 per cent pectinous substances
Pomegranate	The somewhat angular fruit resembling an orange in size and color, of a tropical, Asiatic Punicaceous tree, *Punica Granatum*. It has a hard rind and many seeds in a crimson pulp of agreeable acid flavor which may be eaten uncooked or made into a beverage
Strawberry	The fruit of different species of *Fragaria*. The average constituents are 3 to 7 per cent sugar, 1 per cent free acid, ½ per cent albuminous substances, and 2 per cent pectinous substances

CHAPTER LXVII

VOLATILE OILS

Volatile oils, or *essential oils*, are found in various plant organs and tissues. In some countries they are called *Ætherolea*. In France and Spain they are called *Essences*, a name which conflicts with our ordinary use of that word which designates an alcoholic solution of a volatile oil. They usually constitute the sapid and odorous principles of the plants in which they exist, and they either preëxist in the tissues, or are produced by the reaction of certain constituents when the tissues are brought into contact with water. Volatile oils are sometimes formed through destructive distillation, as the oils of tar and of amber, these being occasionally referred to as *pyrolea*.

The volatile oils are sometimes hydrocarbons, although with these are frequently associated alcohol- or ketone-like bodies called *camphors*, and products of oxidation known under the general name of resins, and, undoubtedly, formed from the hydrocarbons. Phenols, aldehydes, esters, ethers, and sulphides are also represented. The hydrocarbons are generally known as *terpenes*, from oil of turpentine, which is taken as a type.

In some volatile oils, as thyme, a separation into a solid and a liquid portion occurs on standing in the cold. The solid portion is frequently known by the name *stearoptene*, and the liquid portion is called *eleoptene*. Some of the stearoptenes are of commercial importance (examples: thymol, camphor, menthol). The eleoptenes are often used as adulterants of volatile oils (examples: oil of camphor and dementholized oil of peppermint).

Wallach, to whom much of our knowledge of volatile oils is due, divides the hydrocarbons into classes, as follows:

1—*True terpenes*, of the formula $C_{10}H_{16}$, of which there are two main groups: (*a*), the *terpane* group, uniting with two molecules of haloid acid or four atoms of bromine; this group includes limonene, dipentene, sylvestrene, terpinolene, terpinene, thujene, and phellandrene, their boiling point being between 175° and 185° C. (347° and 365° F.); (*b*), the *camphene* group, uniting with one molecule of haloid acid or two atoms of bromine; this group includes pinene, bornylene, camphene, and fenchene, and they boil between 151° and 161° C. (303.8° and 321.8° F.).

2—*Hemiterpenes*, of the formula C_5H_8, such as isoprene.

3—*Polyterpenes*, such as cedrene, cubebene, etc., of the formula $C_{15}H_{24}$ (sesquiterpenes); colophene, of the formula $C_{20}H_{32}$; and caoutchouc, of the formula $(C_{10}H_{16})x$.

Hydrocarbons other than those of the terpene class or derivable from them occur very sparingly in the natural oils. Thus there is of the paraffin series of saturated hydrocarbons, *heptane*, C_7H_{16}, occurring in the oil from the *Pinus sabiniana*, or California *digger pine*, and solid hydrocarbons of the same series in oil of rose, and probably in oils of wintergreen and sweet birch. Of the benzene series there is a single representative in *cymene*, $C_{10}H_{14}$, found in the oils of the Thymus and Monarda species.

In addition to these naturally occurring hydrocarbons, there is a class of artificially prepared hydrocarbons known as *hydroterpenes*, such as dihydrodipentene from dipentene, menthene and carvomenthene from menthol and carvone.

The terpenes in general are practically insoluble in water, but soluble in alcohol, ether, chloroform, benzene, petroleum benzin, and the fixed and volatile oils.

Many of the essential oils, however, owe their essential character and their value to other constituents than hydrocarbons. A brief consideration of the most important of these will be found in the Chapter on Perfumes, Part VI, page 1211.

Color of Volatile Oils—Most oils are colorless when pure and fresh, or can be made colorless by redistillation. Upon exposure to the air they acquire various colors, becoming green, as in oil of wormwood; yellow, as in oil of peppermint; red, as in oil of origanum; brown, as in oil of cinnamon. The blue color of oil of chamomile is an inherent property of the oil even when freshly distilled and is said to be due to a constituent which has been named *azulene* or *cærulein*.

Odor—The odors of volatile oils are extremely variable. It is their most characteristic feature. The odor of an oil is sensibly modified by exposure to the air. Oil of turpentine may be rectified by redistillation in an atmosphere of carbon dioxide, or *in vacuo*, so that it will be almost odorless, or have an agreeable, fragrant odor. A very slight exposure to the air is sufficient, however, to restore the well-known unpleasant odor. Other terpene containing oils are quickly oxidized and the delicacy and fineness of their flavor and odor seriously impaired. This is especially true of the oils of orange and lemon peel.

Taste—The tastes of volatile oils are almost as variable as their odors. Some are sweet, others have a mild, pungent, hot, acrid, caustic, or burning taste.

Density—The specific gravity of official volatile oils also varies (from 0.842 to 1.172). They are mostly lighter than water.

Optical Activity—This important physical factor is used in determining the purity of many oils. It is explained at length under the U. S. P. Test (see page 1524).

Refractive Index—This factor is of increasing importance, as it serves as a delicate test, chiefly for the purity of oils and fats. It is explained under the U. S. P. Test (see page 1525).

Boiling Point—This factor is also variable. The oils volatilize to some extent at ordinary temperatures and diffuse their peculiar odors. One of the principal distinctions from fixed oils is the fact that they completely vaporize on heating. When sufficiently heated, they take fire, and burn with a bright flame.

Solubilities—Water is a poor solvent for volatile oils, although it acquires a decided odor and flavor when brought in contact with the oil in a finely divided state, as has been shown under medicated waters. Alcohol, ether, chloroform, glacial acetic acid, petroleum benzin, benzene, and many other organic solvents will dissolve volatile oils. Alcohol is a better solvent for the oxygenated oils than for the terpenes. Volatile oils freely dissolve fixed oils, fats, resins, camphors, sulphur and phosphorus.

Exposure to Light and Air injures the quality and destroys the fragrance of volatile oils. Ozone is frequently developed, and, after extended exposure, the oils thicken and become resinified, or deposit crystalline compounds. The whitening of corks, inserted for a long time in bottles containing certain volatile oils is due to the bleaching action of the ozone which is gradually produced during their decomposition. This is true only of oils containing notable amounts of terpenes. Volatile oils should be kept in well-filled tightly stoppered, amber-colored bottles, in a cool place. A suggestion has been made to

replace the air with nitrogen in original packages to prevent oxidation. Storage in tin cans causes pronounced deterioration in odor and the development of color.

Volatile oils do not deteriorate so readily when mixed with alcohol, and it is the practice of some pharmacists to preserve them in this manner. Fixed oils, when present to the extent of five or ten per cent, have a remarkable preserving power, even upon such easily decomposed oils as those of the citrus family. In using oils so preserved allowance must be made for the dilution.

Action of Acids, Alkalies, etc.—Nitric acid, if strong, decomposes volatile oils with great rapidity. Iodine reacts with some oils with explosive violence. Alkalies affect volatile oils containing esters or phenolic compounds, as the oils from clove, gaultheria, cinnamon, etc.

Adulterations—The volatile oils are costly enough to tempt the cupidity of some manufacturers of these products. A fixed oil is sometimes used to adulterate the volatile oil. This adulteration may be detected by dropping the suspected oil on a piece of filter paper. The stain of a pure volatile oil is not permanent. By slightly heating the volatile oil it should vaporize; if fixed oil is present, the stain remains after the odor has disappeared. Alcohol may be detected by shaking the mixed oil in a graduated tube with glycerin or water. The volume of the oil will be diminished, and that of the water or glycerin correspondingly increased, in proportion to the amount of alcohol present. This test is not susceptible of fine determination, because of a slight solubility of volatile oils in water and in mixtures of alcohol and water. Metallic sodium, calcium chloride, aniline red, have all been used to show the presence of alcohol and traces of water in volatile oils. The adulteration of volatile oils by the addition of cheaper grades of the same oil, or by using a cheaper oil having a similar odor, is largely practiced. The only reliable test here is the use of the senses of smell and taste, applied to dilutions of the oil in various media. By practice, the sense of smell can be highly developed by the pharmacist, perfumer, or analyst. The specific rotary power, the index of refraction, the amount of iodine absorbed, and the saponification number, or the amount of potassium hydroxide absorbed by the ester to form a potassium salt, have all been used with more or less success in detecting adulterations. The detection of adulterations in volatile oils is difficult, and as a rule those who practice this nefarious art are very skilful. The U. S. P. has included a number of assays to indicate the required percentage of the valuable constituents.

Preparation of Volatile Oils

Volatile oils are generally obtained from plants by the following methods: 1. Distillation with steam. 2. Distillation *per se*. 3. Expression. 4. Solution.

1. **Distillation with Steam**—This is the method most frequently employed. The general formula is as follows: Place the substance from which the oil is to be extracted into a still (see Distillation, page 141), and add enough water to cover it; then distil by a regulated heat into a large condenser. Separate the distilled oil from the water which comes over with it.

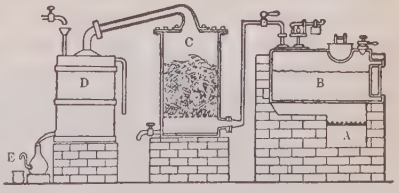
The substances from which the volatile oils are extracted may be employed in either the recent or the dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt or by means of glycerin, as they afford little or no oil after desiccation. Dried substances, such as sandalwood, cloves, cinnamon bark, etc., before being submitted to distillation, require to be macerated in water till they are thor-

oughly penetrated by this fluid; and, to facilitate the action of the water, it is necessary, when of a hard or tough consistence, that they should be properly comminuted.

The water which is added to the substance to be distilled answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, though in most instances it readily rises with the vapor of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partly decomposed. Some oils, however, will not ascend readily with steam at 100° C. (212° F.), and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 108.4° C. (227.1° F.) (see page 113). Other oils, again, may be volatilized with water at a temperature below the boiling point and may be distilled with the aid of a partial vacuum. To prevent injury from heat, it has been recommended to suspend the substance containing the oil in a basket, or to place it upon a perforated shelf, in the upper part of the still, so that it may be penetrated by the steam without being in direct contact with the water. Steam can be very conveniently applied for this purpose by causing it to pass through a coil of tube, of an inch or three-quarters of an inch bore, placed in the bottom of a common still (see page 141). In some instances it is desirable to conduct the steam immediately into the still near the bottom, by which the contents are kept in a state of brisk ebullition (see Fig. 436). The distillation of volatile oils is now conducted on a large scale with enormous stills. (For description and illustrations see Gildemeister and Hoffman on Volatile Oils, translated from the German by Prof. Edward Kremers.)

The quantity of water added is of importance. Too large an amount causes loss by holding the oil in solution when the mixed vapors are condensed. On the contrary, if the quantity is too small, there will be danger of the substance in the still adhering to the sides of the vessel and thus becoming burnt. The cage shown on page 141 will be found useful in this connection. Where the yield of oil is very small, the process of *cohobation* is applicable; this consists in repeatedly returning the aqueous portion of the distillate to the still, the water in this way becoming supersaturated, and the yield of oil increased. Fig. 436 illustrates one method of distilling volatile oils from plants. *A* shows the fire box, *B* the steam boiler, *C* the tank containing the plant on the slat or perforated bottom, and *D* the condenser.

FIG. 436



Distillation of volatile oils

2. **Distillation** *per se*—By this is meant the distillation of certain bodies without the use of water (*per se*, "by itself"). This is done in the cases of certain oleoresins, copaiba, etc., water not being required in the process, and always being difficult to separate from the distillate.

3. **Expression** (see page 225)—This method is very limited in its application and generally produces the most fragrant products, because there are very few volatile oils, the aroma of which is not injuriously affected by the action of heat. The volatile oils of the Citrus family (orange, lemon, bergamot, and lime), are generally made by expressing the rind of the fresh fruit. These are usually known as "hand pressed". Three methods are practiced: (*a*) The sponge process; (*b*) the ecuelle method; and (*c*) the machine process.

In the sponge process the rind is removed from the fruit, and, after dipping in water, is pressed by hand, the oil collecting in a shallow bowl from which it is transferred to a larger container for separation.

In the ecuelle method the fruit is rolled about in hollow bowls, the walls of which are covered with spikes. The oil cells are punctured and the oil which exudes is collected in the hollow handle.

In the machine process either the sponge or the ecuelle processes are adapted to machines which perform the operation on a larger scale.

4. **Extraction**—Some volatile oils are so readily decomposed that they are dissociated by distillation, or exist in such minute traces as to make their commercial production impracticable. In such cases the odorous principle may be extracted by some form of solution or absorption. This may be effected by maceration, digestion, percolation with an appropriate immiscible solvent, enfleurage, or extraction with a volatile solvent.

Maceration—In obtaining volatile oils by maceration, the odorous portions of the plant (generally fragrant flowers) are allowed to remain in contact with a bland, inodorous, fixed oil or fat; the oil or fat absorbs the odor, and after a certain length of time the oil is strained and is subsequently used in the manufacture of perfumes in a manner similar to pomades. The flowers extracted by this method are chiefly cassie, rose, violet, orange flowers, narcissus, and lily.

Digestion—This process is similar to maceration, except that a moderate heat is employed, by the use of a salt bath, to aid in the extraction.

Enfleurage was at one time largely used for extracting the odors of very delicate flowers. It is a cold process, and consists in spreading a thin layer of purified inodorous fat upon both sides of sheets of glass, held in frames, known as a *chassis*. These resemble an ordinary window sash, with one pane of glass in each. The flowers are spread lightly upon the surface of the fat, and a number of chassis thus prepared, are arranged in tiers so that the flowers are between layers of fat. The whole is left undisturbed for a time varying from twelve hours to four days. The resulting fatty product impregnated with the floral odor is called a "pomade". When strong pomades are desired, the flowers are replaced daily by fresh lots, as long as the absorption continues, the old flowers being removed by the use of a vacuum. The pomades are known commercially as Nos. 6, 12, 18, 24 and 36, the numbers indicating the relative strength. The absorbed volatile products are then obtained from the pomade by washing in pure alcohol in an appropriate mixing device. The alcohol dissolves out the floral odors and leaves only a trace of the fat behind, and this trace may be separated by subjecting it to a cold atmosphere in a refrigerator, when the congealed fat can be filtered out. The enfleurage process is used for jasmine, tuberose, cassie, rose, violet, jonquil, lily, orange flowers, and a few others.

The pomades are mostly imported from Grasse, France, but their use today is very limited, having been largely replaced by *concretes* and *absolutes* (see page 1210).

Percolation with Volatile Solvents—The chief solvent employed is a highly purified petroleum benzin of a specific gravity of 0.650. The solvent is allowed to flow through the flowers which are arranged on trays in the apparatus. The extraction requires about eight hours. The volatile solvent is then removed by vacuum distillation and the resulting product is known as a *concrete*.

These concretes contain the plant or flower waxes and are removed by dissolving the odorous portion in strong alcohol and separating the insoluble waxes by filtration. Small quantities of alcohol-soluble waxes are removed by

chilling to 20° C. below zero when the resulting products are known as *absolutes*. These products, although very costly, are largely used in perfumery, their great odor value making their employment economically possible.

Synthetic Perfumery—Many of the constituents of volatile oils, already enumerated, and other alcohols, aldehydes, ketones, esters, etc., are now manufactured synthetically for use in perfumery. This has become an extensive business and requires a comprehensive knowledge of organic synthesis and methods for the purification of the resulting compounds. (See the Chapter LXXVI on Perfumery.)

For the purpose of study, the volatile oils are grouped according to botanical families, as follows:

Official Products from the Rutaceæ

The Family Rutaceæ furnishes valuable products to medicine and pharmacy.

AURANTII AMARI CORTEX. U.S. Bitter Orange Peel, Bitter Orange; Curaçao Orange Peel, Bigarade Orange

[Aurant. Amar. Cort.]

Bitter Orange Peel is the dried rind of the unripe fruit of *Citrus Aurantium* Linné (Fam. *Rutaceæ*).

Description and Physical Properties—Thin, irregular bands (ribbons) or quarters, outer surface yellowish- or reddish- or greenish-brown with numerous, minute pits and fine reticulate ridges; inner surface whitish with many slight conical projections and fine anastomosing lines formed by the vascular bundles; fracture hard, short; odor fragrant and aromatic; taste aromatic and bitter. For further description and tests see the U. S. P. X.

U. S. P. Preparations—Tinctura Aurantii Amari; Tinctura Cinchonæ Composita; Tinctura Gentianæ Composita.

N. F. Preparations—Infusum Gentianæ Compositum; Tinctura Amara.

The inner thick part of the peel from the bitter orange contains a volatile oil and *hesperidin*, having the formula $C_{22}H_{26}O_{12}$. This is a glucoside, which yields, on treatment with sulphuric acid, *hesperetin*, $C_{16}H_{14}O_6$, and rhamnose, $C_6H_{12}O_5$. It also contains a small quantity of volatile oil. It is used to communicate flavor, and as a bitter tonic. The dose is ten to forty grains (0.6 to 2.6 Gm.).

AURANTII DULCIS CORTEX. U.S. Sweet Orange Peel

[Aurant. Dulc. Cort.]

Sweet Orange Peel is the fresh, outer rind of the ripe fruit of *Citrus Aurantium* var. *sinensis* Linné (Fam. *Rutaceæ*).

In separating the rind the white portion must be discarded as far as possible since it contains no oil but does contain hesperidin which would impart a bitter taste to the preparations in which the orange peel is intended for a flavor.

Description and Physical Properties—The outer, orange-yellow layer recently separated by grating or paring and consisting of epidermal cells, parenchyma, and oil reservoirs with globules of volatile oil; odor highly fragrant; taste pungently aromatic.

U. S. P. Preparations—Tinctura Aurantii Dulcis; Syrupus Aurantii (from Tincture).

N. F. Preparations—Elixir Gentianæ Glycerinatum; Elixir Pepsini et Rennini Compositum; Elixir Taraxaci Compositum; Elixir Terpini Hydratis.

Uses—Sweet orange peel owes its virtues to the volatile oil found in the epidermis. It also communicates a yellowish color to the preparations made with it, and is used exclusively as a flavoring substance. The 50 per cent tincture, made from the freshly grated rind, has a finer flavor than the oil and is less likely to become terebinthinate.

OLEUM AURANTII. U. S. Oil of Orange

[Ol. Aurant.—Orange Oil, Oil of Sweet Orange]

The volatile oil obtained by expression from the fresh peel of the ripe fruit of *Citrus Aurantium* var. *sinensis* Linné (Fam. *Rutaceæ*). Oil of Orange which has a terebinthinate odor must not be dispensed.

This oil consists of *d-limonene* to the extent of at least 90 per cent; of the remainder, about 5 per cent are the odorous constituents, among which are *decylic aldehyde*, one of the most important, *linalol*, *l-terpineol*, *d-terpineol*, *nonyl alcohol*, *methyl anthranilate*, and traces of *caprylic acid esters*. It may be preserved by shaking it with one-eighth of its volume of distilled water, allowing it to separate, then removing the essential oil, filtering rapidly if necessary, and mixing the filtered oil with 95 per cent alcohol in the proportion of one volume of the oil to seven volumes of alcohol.

It may also be preserved by adding 10 per cent of its volume of olive oil. Kept under the usual conditions it is very prone to decompose, and rapidly acquires a terebinthinate odor.

Description and Physical Properties—A yellow liquid, having the characteristic odor and taste of the outer part of sweet orange peel.

Tests for Identity and Purity—The Oil does not form a clear solution with 2 volumes of 90 per cent alcohol, by volume (*washed citrus oils*). It is soluble in all proportions in dehydrated alcohol and in carbon disulphide, and in an equal volume of glacial acetic acid.

Specific gravity: 0.842 to 0.846 at 25° C.

Optical rotation: not less than +94° and not more than +99° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4723 to 1.4737 at 20° C., page 1525.

A solution of recently expressed Oil of Orange in dehydrated alcohol is neutral to moistened litmus paper.

The Oil meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

A 25 Gm. portion of Oil of Orange evaporated to dryness at a temperature not exceeding 100° C. yields not less than 2 per cent of residue (*washed citrus oils*).

Place 50 cc. of Oil of Orange in a 250 cc. three-bulb Ladenburg flask of approximately the following dimensions: The lower or main bulb, 6 cm. in diameter, with the smaller condensing bulbs 3.5 cm., 3.0 cm. and 2.5 cm., respectively, in diameter; the distance from the bottom of the flask to the side arm, 20 cm. Distil the Oil at the rate of 1 drop per second until the distillate measures 5 cc.: the angle of rotation of the distillate is equal to that of the original Oil, or does not differ more than 2 degrees from it, and the refractive index of the distillate is not less than 0.0008 and not more than 0.0015 lower than that of the original Oil at 20° C.

Preserve in small, completely filled, well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparations—Elixir Aromaticum (from Compound Spirit); Spiritus Aurantii Compositus.

N. F. Preparations—Elixir Cardamomi Compositum (from Compound Spirit); Elixir Ferri Pyrophosphatis, Quininæ et Strychninæ; Elixir Vanillini Compositum (from Compound Spirit); Elixir Pepsini Compositus; Liquor Ferri Peptonati; Liquor Ferri Peptonati et Mangani; Spiritus Cardamomi Compositus; Spiritus Myrciæ Compositus; Spiritus Vanillini Compositus; Syrupus Quinidinæ; Tabellæ Sulphuris et Potassii Bitartratis; Trochisci Eucalypti Gummi.

Uses—It is used as a flavoring agent in elixirs and other preparations.

Average dose—1½ minims (0.1 cc.).

For the *Oils of Bitter Orange* and *Orange Flowers*, which are official in the N. F., see page 956.

LIMONIS CORTEX. U.S. Lemon Peel

[Limon. Cort.—Fresh Lemon Peel]

Lemon Peel is the outer yellow rind of the fresh ripe fruit of *Citrus medica* var. *Limonum* (Risso) Hooker filius (Fam. *Rutaceæ*).

Lemon peel is principally used to communicate flavor and color to spirit and syrup of lemon. It contains a volatile oil and *hesperidin*.

Description and Physical Properties—The outer lemon-yellow or dark-yellow layer, recently separated by grating or paring; consisting of the epidermis and numerous parenchyma cells containing yellow chromoplastids and large oil reservoirs with globules of the volatile oil; odor fragrant, distinctive; taste aromatic.

U.S.P. Preparation—Tinctura Limonis.

OLEUM LIMONIS. U.S. Oil of Lemon

[Ol. Limon.—Lemon Oil]

The volatile oil obtained by expression from the fresh peel of the fruit of *Citrus medica* var. *Limonum* (Risso) Hooker filius (Fam. *Rutaceæ*). Oil of Lemon yields not less than 4 per cent of the aldehydes of Oil of Lemon, calculated as citral [$C_{10}H_{16}O$]. Oil of Lemon which has a terebinthinate odor must not be dispensed.

This important volatile oil contains a number of constituents, among the most important of which is *citral*, about 4 to 5½ per cent. *Pinene* is present in small amount, also *camphene*, *phellandrene*, and *γ-terpinene*. About 90 per cent of the oil, however, consists of *d-limonene*. Traces of many other substances are also present such as *octyl* and *nonyl* aldehydes, *citronellal*, etc., and about 2 per cent of a solid substance known as *citraptene* or *lemon-camphor*. When fresh, the oil has the fragrant odor of lemons. It may be preserved from the effects of oxidation by the addition of 5 per cent of alcohol and separation from the sediment. Five per cent of olive or cottonseed oil will also preserve it indefinitely. This oil is prepared by expression. The method of its production has been described on page 951.

Description and Physical Properties—A pale yellow or greenish-yellow liquid, having the characteristic odor and taste of the outer part of fresh lemon peel.

Tests for Identity and Purity—The Oil is soluble in 3 volumes of alcohol, and in all proportions in dehydrated alcohol, carbon disulphide, and in glacial acetic acid.

Specific gravity: 0.851 to 0.855 at 25° C.

Optical rotation: varies from +57° to +64° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4744 to 1.4755 at 20° C., page 1525.

A solution of the recently expressed Oil in alcohol (1 in 3) is neutral or only slightly acid to moistened litmus paper.

Oil of Lemon when distilled as described under *Oleum Aurantii*, page 954, gives the following results: The angle of rotation of the first 5 cc. is not more than 5 degrees less than that of the original Oil. The refractive index of this same portion is not less than 0.0020 and not more than 0.0027 lower than that of the original Oil.

Assay—Place about 15 cc. of Oil of Lemon in a tared, 250 cc. Erlenmeyer flask, and weigh accurately. Add 10 cc. of an alcoholic solution of phenylhydrazine (1 in 10) (not darker in color than pale yellow), and allow it to stand for thirty minutes at room temperature. Then add 3 drops of methyl-orange T.S., and neutralize the liquid by the addition of half-normal hydrochloric acid. If difficulty is experienced in determining the end point of the reaction, continue the titration until the liquid is distinctly acid, transfer it to a separatory funnel, and after the layers have separated draw off the alcoholic portion. Wash the oil remaining in the funnel with distilled water, adding the washings to the alcoholic solution, and titrate the latter with half-normal sodium hydroxide. Carry out a blank test identical with the foregoing, omitting the Oil of Lemon, and note the amount of half-normal hydrochloric acid consumed. Subtract the number of cc. of half normal sodium hydroxide from the number of cc. of half-normal hydrochloric acid consumed in the test containing the Oil of Lemon, and this result from the number of cc. of half-normal hydrochloric acid consumed in the test without the Oil of Lemon. Each cc. of this difference corresponds to 0.07609 Gm. of aldehydes calculated as citral.

Preserve in completely filled, well-stoppered, amber-colored bottles, in a cool place, protected from light.

This assay is explained on page 1460.

U. S. P. Preparations—Elixir Aromaticum (from Compound Spirit of Orange); Liquor Magnesii Citratis; Spiritus Ammoniæ Aromaticus; Spiritus Aurantii Compositus.

N. F. Preparations—Acetum Aromaticum; Linimentum Terebinthinæ Aceticum; Mistura Oleo-Balsamica; Spiritus Odoratus; Syrupus Eriodictyi Aromaticus; Syrupus Sennæ Aromaticus.

Uses—Oil of lemon is used as a flavor in the official preparations named above.

Average dose—1½ minims (0.1 cc.).

OLEUM AURANTII AMARI. N. F. Oil of Bitter Orange
[Ol. Aurant. Amar.]

A volatile oil obtained by expression from the fresh peel of the bitter orange, *Citrus Aurantium* Linné (Fam. *Rutaceæ*). Preserve it in small, well-stoppered, amber-colored bottles, in a cool place, protected from light. Oil of Bitter Orange having a terebinthinate odor is not to be dispensed.

Official Description—A pale yellow liquid.

Odor, Taste, and Reaction—Characteristic, aromatic odor of the Seville orange, and an aromatic, somewhat bitter taste. The alcoholic solution is neutral to litmus paper.

Solubility—Soluble in four volumes of alcohol. Also soluble in all proportions in dehydrated alcohol and in an equal volume of glacial acetic acid.

Specific gravity: 0.842 to 0.848 at 25° C. (77° F.).

Tests for Identity and Purity—It is dextrorotatory, the angle of rotation varying from +88° to +98° in a 100 mm. tube, at 25° C. (77° F.).

Introduce 50 cc. of Oil of Bitter Orange into a 200 cc., three-bulb, fractionating flask. Distil the Oil at the rate of 2 cc. per minute until a distillate measuring 5 cc. has been collected. The angle of rotation of this distillate is equal to, or only slightly lower, than that of the original Oil.

N. F. Preparation—Elixir Aurantii Amari.

Uses—It is used as an adjuvant and flavor. The dose is three minims (0.2 cc.).

OLEUM AURANTII FLORUM. N. F. Oil of Orange Flowers
[Ol. Aurant. Flor.—Oil of Neroli]

A volatile oil distilled from the fresh flowers of the bitter orange, *Citrus Aurantium* Linné (*Citrus vulgaris* Risso, *Citrus Bigaradia* Risso) (Fam. *Rutaceæ*). Preserve it in small, amber-colored, well-stoppered bottles, in a cool place, protected from light.

Official Description—A pale yellow, slightly fluorescent, neutral liquid.

Odor, Taste, and Reaction—A distinctive fragrant odor similar to that of orange blossoms and an aromatic, at first sweet, then somewhat bitter taste. The alcoholic solution is neutral to litmus paper.

Solubility—Soluble in an equal volume of alcohol, the solution having a violet fluorescence. Also soluble in two volumes of 80 per cent alcohol, the solution becoming cloudy on the further addition of alcohol of the same percentage.

Specific gravity: 0.868 to 0.880 at 25° C. (77° F.).

Tests for Identity and Purity—It is dextrorotatory, the angle of rotation varying from +1° 30′ to + 5°, in a 100 mm. tube, at 25° C. (77° F.).

When agitated with a concentrated solution of sodium bisulphite, it assumes a permanent purple-red color.

N. F. Preparation—Spiritus Odoratus.

Uses—It is used as a perfume, being the dominant odor in Cologne water. Several less valuable varieties of the oil are commercially known. These are designated as *Bigarade* (from the flowers of the bitter orange, the ordinary neroli oil), *Portugal* (from the flowers of sweet orange), and *Petit-grain* (from the leaves and young shoots of the bitter orange). The finest variety is known as *Petale*.

OLEUM BERGAMOTTÆ. N. F. Oil of Bergamot
[Ol. Bergam.]

A volatile oil obtained by expression from the rind of the fresh fruit of *Citrus Aurantium* Linné var. *Bergamia* (Risso et Poiteau) Wight et Arnott (Fam. *Rutaceæ*), and containing not less than 36 per cent of ester, calculated as linalyl acetate. Preserve it in small, amber-colored, well-stoppered bottles, in a cool place, protected from light.

Official Description—A green or greenish-yellow liquid, neutral or only faintly acid.

Odor and Taste—A characteristic fragrant odor and an aromatic bitter taste.

Solubility—Two volumes of the Oil, when mixed with one volume of alcohol, give a clear solution and this does not become turbid on the further addition of alcohol. It is soluble in two volumes of

80 per cent alcohol with not more than a slight cloudiness, and no separation of oil globules. Also soluble in all proportions in glacial acetic acid.

Specific gravity: 0.875 to 0.880 at 25° C. (77° F.).

Tests for Identity and Purity—It is dextrorotatory, the angle of rotation varying from +8° to +24°, in a 100 mm. tube, at 25° C. (77° F.).

Fixed Oils—Evaporate in a tared dish on a water bath about 2 Gm. of the Oil, accurately weighed, until the odor has completely disappeared; a soft green residue remains, corresponding to not more than 6 per cent of the Oil.

Chlorinated Compounds—To 2 Gm. of Oil of Bergamot add 10 cc. of alcoholic potassium hydroxide V.S., free from chloride, evaporate to dryness and incinerate. Extract the ash with distilled water and acidify with diluted nitric acid: no cloudiness is produced on the addition of silver nitrate T.S.

Assay—To 2 Gm. of the Oil add 20 cc. of half-normal alcoholic potassium hydroxide and heat the mixture in a flask on a water bath, under a reflux condenser, for a half hour. Cool the mixture, add 100 cc. of distilled water and titrate with half-normal sulphuric acid, using phenolphthalein T.S. as indicator. Not more than 12.6 cc. of half-normal sulphuric acid is required, corresponding to not less than 36 per cent of ester, calculated as linalyl acetate, in the Oil. Each cc. of half-normal potassium hydroxide corresponds to 0.09808 Gm. of ester, calculated as linalyl acetate.

For a description of this assay, see page 1461.

N. F. Preparation—Spiritus Odoratus.

Uses—A constituent of Cologne water, and also much used in other perfumes, chiefly in oils and pomades for the hair.

Official Products from the Labiatæ

The family of the mints is a strongly marked group, the members of it being remarkable for their botanical analogy and for the similarity of their chemical constituents.

MENTHA PIPERITA. U. S. Peppermint

[**Menth. Pip.**—Peppermint Herb or Leaves]

Peppermint consists of the dried leaves and tops of *Mentha piperita* Linné (Fam. *Labiatæ*).

Peppermint contains not more than 2 per cent of stems over 3 mm. in diameter, or other foreign organic matter.

Description and Physical Properties—Leaves more or less crumpled and frequently detached from the stem; ovate-oblong to oblong-lanceolate, petiole from 4 to 15 mm. in length, slightly pubescent, blade from 1 to 9 cm. in length, acute and sharply serrate, light green to purplish-brown; upper surface nearly glabrous, lower surface glandular-hairy, especially on the veins; stem quadrangular, from 1 to 3 mm. in diameter, glabrous except for a few scattered deflexed hairs; flower-whorls usually in a compact, oblong or oval spike, from 1 to 1.5 cm. in breadth, rounded at the summit, and in fruit attaining a length of from 3 to 7 cm.; bracts, oblong-lanceolate, from 4 to 7 mm. in length; calyx tubular, equally 5-toothed, pubescent and glandular-punctate, often dark purple in color; corolla tubular-campanulate, 4-cleft, about 3 mm. in length and often light purple; stamens 4, short and equal; nutlets ellipsoidal, about 0.5 mm. in diameter, blackish-brown; odor aromatic, characteristic; taste aromatic, pungent, followed by a cooling sensation in the mouth. For further description, see the U. S. P. X.

U. S. P. Preparation—Spiritus Menthæ Piperitæ.

Uses—Its properties are due to the presence of about 2 per cent of a volatile oil which contains *menthol*. It is largely cultivated, and is a grateful aromatic stimulant. It is used in making spirit of peppermint. The dose is one drachm (4 Gm.).

OLEUM MENTHÆ PIPERITÆ. U. S. Oil of Peppermint

[**Ol. Menth. Pip.**—Peppermint Oil]

The volatile oil distilled from the fresh, over-ground parts of the flowering plant of *Mentha piperita* Linné (Fam. *Labiatæ*), rectified by steam distillation.

Oil of Peppermint yields not less than 5 per cent of esters, calculated as menthyl acetate [$C_{10}H_{19}.C_2H_3O_2$], and not less than 50 per cent of total menthol [$C_{10}H_{19}.OH$], free and as esters.

This is one of the most important of the group of volatile oils. It has been found to contain the following constituents: acetaldehyde, isovaleraldehyde, dimethyl sulphide, amyl acetate, isovaleric aldehyde, pinene, phellandrene, cineol, limonene, *menthone*, $C_{10}H_{18}O$, menthol, the acetate and isovalerate of menthyl, *a-lactone*, $C_{10}H_{16}O_2$, and cadinene. Menthol, its oxidation product menthone, and the acetic and isovaleric esters of menthyl have been identified as present in English and French peppermint oils, which probably also contain most of the other constituents mentioned above. Menthol and its esters are regarded as the main constituents of oil of peppermint. The dimethyl sulphide and some of the other constituents are objectionable from the flavoring standpoint, and are largely removed by the steam distillation which is required for rectification. The polariscope has been shown to be an uncertain guide in determining the quality of oil of peppermint. It is distilled in large quantities in Michigan, Ohio, Indiana, and New York from cultivated plants. *Menthol* is official, and the proportion which should be present forms the basis of the official assay (see below). The eleoptene or dementholized oil is often found in the market as a substitute in whole or in part for the genuine oil.

Description and Physical Properties—A colorless liquid, having a strong, penetrating odor of peppermint, and a pungent taste, followed by a sensation of cold when air is drawn into the mouth.

Tests for Identity and Purity—The Oil is soluble in 4 volumes of 70 per cent alcohol by volume, showing not more than a slight opalescence and no separation of oil globules (*dementholized or impure peppermint oil*).

Specific gravity: 0.896 to 0.908 at 25° C.

Optical rotation: varies between −23° and −33° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4600 to 1.4710 at 20° C., page 1525.

A solution of the recently rectified Oil in 70 per cent alcohol (1 in 4) is neutral to moistened litmus paper.

Distil 1 cc. from 25 cc. of Oil of Peppermint, and carefully superimpose the distillate on 5 cc. of mercuric chloride T.S. in a test tube: a white film does not form at the zone of contact within one minute (*dimethyl sulphide found in nonrectified peppermint oils*).

Assay for Esters—Place 10 cc. of Oil of Peppermint in a tared, 125 cc. Erlenmeyer flask, and weigh accurately. Add 25 cc. of half-normal alcoholic potassium hydroxide, connect the flask with a reflux condenser, and boil the mixture on a water bath for one hour. Allow the mixture to cool, disconnect the flask from the condenser, and titrate the excess of alkali with half-normal sulphuric acid, using 10 drops of phenolphthalein T.S. as indicator. Subtract the number of cc. of half normal sulphuric acid required for neutralization from the 25 cc. of half-normal alcoholic potassium hydroxide taken, multiply the difference by 9.912, and divide this product by the weight of Oil of Peppermint taken: the result shows the per cent of esters calculated as menthyl acetate.

For an explanation of this assay, see page 1461.

Assay for Total Menthol—Place 10 cc. of Oil of Peppermint in an acetylization flask of 100 cc. capacity, add 10 cc. of acetic anhydride, and 1 Gm. of powdered anhydrous sodium acetate. Boil the mixture gently for one hour, cool, disconnect the flask from the condenser, transfer the mixture to a small separatory funnel, rinsing the acetylization flask with three successive 5 cc. portions of warm distilled water, and add the rinsings to the separatory funnel. When the liquids have completely separated, remove the aqueous layer, and wash the remaining oil with successive portions of sodium carbonate T.S., diluted with an equal volume of distilled water, until the mixture is alkaline to 2 drops of phenolphthalein T.S. Dry the resulting Oil with fused calcium chloride, and filter. Transfer 5 cc. of the dry acetylized oil to a tared, 100 cc. Erlenmeyer flask, note the exact weight, add 50 cc. of half-normal alcoholic potassium hydroxide, connect the flask with a reflux condenser, and boil the mixture on a water bath for one hour. Allow the mixture to cool, disconnect the flask from the condenser, and titrate the excess of alkali with half-normal sulphuric acid, using 10 drops of phenolphthalein T.S. as indicator. Calculate the per cent of menthol by the following formula:

$$\text{Per cent of total menthol} = \frac{A \times 7.811}{B - (A \times 0.021)} \times [1 - (E \times 0.0021)]$$

A is the result obtained by subtracting the number of cc. of half-normal sulphuric acid required in the above titration from the number of cc. of half-normal alcoholic potassium hydroxide originally taken, *B* is the weight of acetylized oil taken, and *E* is the per cent of esters calculated as menthyl acetate.

For an explanation of this assay see page 1461.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparations—Aqua Menthæ Piperitæ; Spiritus Menthæ Piperitæ.

N. F. Preparations—Acetum Aromaticum; Cataplasma Kaolini; Elixir Catharticum Compositum (from Spirit); Elixir Euphorbiæ Compositum; Gargarisma Guaiaci Composita; Lavatio Ori; Linimentum Opii Compositum; Mistura Carminativa; Mistura Chloroformi et Morphinæ Composita; Mistura Opii et Rhei Composita (from Spirit);

Mistura Rhei Alkalina (from Spirit); Mistura Rhei Composita (from Spirit); Oleum Hyoscyami Compositum; Pilulæ Catharticæ Vegetabiles; Pilulæ Rhei Compositæ; Syrupus Ficorum Compositus (from Spirit); Tabellæ Menthæ Piperitæ.

Uses—Oil of peppermint is a local anesthetic, antiseptic, and carminative. It is much used in sick stomach and also as a flavor in the dose of one and one-half minims (0.1 cc.) and as an ingredient in the official preparations listed above.

MENTHOL. U.S. Menthol

[Peppermint Camphor, Peppermint Crystals, Headache Crystals]

An alcohol [$C_{10}H_{19}OH$] obtained from oil of peppermint or other mint oils. The oil of peppermint owes its odor to *menthol* which is a stearoptene obtained from it through fractional distillation, cooling, and crystallization. It is sometimes called *peppermint camphor.*

Description and Physical Properties—Colorless, acicular crystals, having a strong, peppermint-like odor.

Menthol is slightly soluble in water; very soluble in alcohol, chloroform, ether, and in petroleum benzin. It is freely soluble in glacial acetic acid, liquid petrolatum, and in fixed or volatile oils.

When menthol is triturated with about an equal weight of camphor, chloral hydrate, phenol, or thymol, the mixture liquefies.

Tests for Identity and Purity—Menthol melts between 42° and 44° C.

Its alcoholic solution is lævorotatory.

Heat 2 Gm. of Menthol in an open dish on a water bath: it gradually volatilizes without leaving more than 0.05 per cent of residue (*wax, paraffin, or inorganic substances*).

Dissolve about 0.1 Gm. of Menthol in 1 cc. of glacial acetic acid, and add 3 drops of sulphuric acid and 1 drop of nitric acid: no green color is produced (*thymol*).

Preserve in well-closed containers, in a cool place.

N.F. Preparations—Dentifricium; Dentilinimentum Aconiti Compositum; Dentilinimentum Aconiti et Iodi Compositum; Inunctum Mentholis; Inunctum Mentholis Compositum; Linimentum Sinapis Compositum; Liquor Antisepticus; Liquor Pepsini Antisepticus; Menthol Camphoratum; Nebula Aromatica; Nebula Mentholis; Nebula Mentholis Composita; Petroxolinum Mentholis; Pulvis Antisepticus.

Uses—Menthol is largely used, compressed into cones, as a local remedy in neuralgia and headache and as a constituent in solutions for nasal and throat sprays, etc. It is also much used in throat lozenges and as a local application to relieve itching.

Average dose—1 grain (0.06 Gm.).

MENTHOL CAMPHORATUM. N.F. Camphorated Menthol

[**Menthol Camph.**—Camphor and Menthol]

	Metric	Alternative
Camphor	**47.5 Gm.**	1 oz. av. 394 gr.
Menthol	**47.5 Gm.**	1 oz. av. 394 gr.
Alcohol	**5.0 Gm.**	87 gr.
To make	**100 Gm.**	4 oz. av.

Reduce the camphor to a powder by triturating it with about one-tenth of its weight of menthol, add the rest of the menthol and continue trituration until the mixture is completely liquefied; then add the alcohol.

Camphorated Menthol may also be prepared by placing the camphor and menthol in a suitable bottle, tightly stoppered, and partially immersing it in hot water until, after occasional agitation, the mixture is completely liquefied. Finally add the alcohol.

In this preparation an *eutectic* mixture is produced having a melting point lower than that of its constituents. This phenomenon of two solids uniting to produce a liquid, without any chemical reaction taking place is not uncommon among organic substances, especially the stearoptenes.

Uses—It is used externally as a local anesthetic and counterirritant.

MENTHA VIRIDIS. U.S. Spearmint

[Menth. Vir.—Spearmint Leaves, Spearmint Herb—Mint]

Spearmint consists of the dried leaves and tops of *Mentha spicata* Linné (*Mentha viridis*, Linné) (Fam. *Labiatæ*).

Spearmint contains not more than 2 per cent of stems over 3 mm. in diameter, or other foreign organic matter.

Description—Leaves about 5 cm. long, subsessile, lance-ovate, acute, serrate, glandular, nearly smooth; branches quadrangular, mostly light green; flowers in terminal, interrupted, narrow, acute spikes, with a tubular, sharply five-toothed calyx, a light purplish, four-lobed corolla, and four rather long stamens; odor aromatic; taste pungent.

For further description see the U. S. P. X.

U. S. P. Preparation—Spiritus Menthæ Viridis.

The spearmint is the mint of culinary use in preparing mint sauce, and also the well-known mint julep. The volatile oil is the only constituent of importance in this plant; the yield is from ½ to 1 per cent. The dose of the drug is one drachm (4 Gm.).

OLEUM MENTHÆ VIRIDIS. U.S. Oil of Spearmint

[Ol. Menth. Vir.—Spearmint Oil]

The volatile oil distilled from the fresh, over-ground parts of the flowering plant of *Mentha spicata* Linné (*Mentha viridis* Linné) (Fam. *Labiatæ*).

Oil of Spearmint yields not less than 43 per cent by volume, of carvone [$C_{10}H_{14}O$].

The German and American oils of spearmint also contain a terpene, *l-limonene*, $C_{10}H_{16}$, and *l-carvone*, $C_{10}H_{14}O$, the latter in the amount of from 35 to 66 per cent. It also contains phellandrene, dihydrocarveol acetate, and the esters of acetic, butyric, and caproic acids. The Russian oil has been found to contain from 5 to 10 per cent of carvone only, but 50 to 60 per cent of linaloöl, together with some cineol and *l-limonene*.

Description and Physical Properties—A colorless, yellow or greenish-yellow liquid, having the characteristic odor and taste of spearmint.

Tests for Identity and Purity—The Oil is soluble in 1 volume of 80 per cent alcohol by volume, forming a clear solution, which becomes cloudy on dilution with more of the alcohol.

Specific gravity: 0.917 to 0.934 at 25° C.

Optical rotation: varies from −38° to −56° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4820 to 1.4900 at 20° C., page 1525.

A solution of the recently distilled Oil in an equal volume of 80 per cent alcohol is neutral or only slightly acid to moistened litmus paper.

Assay—Proceed as directed under *Oleum Cari*, page 965, using 10 cc. of Oil of Spearmint. The oily layer measures not more than 5.7 cc., indicating the presence of not less than 43 per cent by volume, of carvone.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparations—Aqua Menthæ Viridis; Spiritus Menthæ Viridis.

Uses—It is used sometimes as a carminative in doses of one and one-half minims (0.1 cc.), and extensively as a flavor, especially in chewing gum.

OLEUM LAVANDULÆ. U.S. Oil of Lavender

[Ol. Lavand.—Oil of Lavender Flowers]

The volatile oil distilled from the fresh flowering tops of *Lavandula Spica* Linné (*Lavandula officinalis* Chaix, *Lavandula vera* DeCandolle) (Fam. *Labiatæ*). Oil of Lavender yields not less than 30 per cent of esters calculated as linalyl acetate [$C_{10}H_{17}.C_2H_3O_2$].

Oil of lavender flowers is most largely used in perfumery. The best quality is distilled at Mitcham, England. It has the same composition and properties as oil of lavender. It is, however, more fragrant and more expensive. The principal constituent of the oil is an alcohol, $C_{10}H_{18}O$, identical with the linaloöl. This alcohol boils at from 197° to 199° C. (386.6° to 390.2° F.), and has a sp. gr. of 0.869 at 20° C. (68° F.). Besides linaloöl, lavender oil contains *linalyl acetate* (from 30 to 45 per cent in the oil from French flowers, and from 7 to 10 per cent in the oil from English flowers), the *butyric ester* of the same alcohol, *geraniol*, a very small amount of *cineol* (more in the English than in the French oil), and sometimes traces of pinene, limonene, and a sesquiterpene.

Oil of Spike Lavender is an inferior grade of lavender oil made from the flowers of *Lavandula spica*. It should be used only in cheaper perfumery, as the odor is inferior to the oil from *Lavandula vera*.

Description and Physical Properties—A colorless or yellow liquid, having the characteristic odor and taste of lavender flowers.

Tests for Identity and Purity—The oil is soluble in 3 volumes of 70 per cent alcohol by volume.

Specific gravity: 0.875 to 0.888 at 25° C.

Optical rotation: varies from −3° to −10° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4600 to 1.4640 at 20° C., page 1525.

Shake 5 cc. of Oil of Lavender with an equal volume of distilled water in a narrow, graduated 10 cc. glass-stoppered cylinder: the volume of the Oil does not diminish (*alcohol*).

Shake 20 cc. of the Oil with 40 cc. of 5 per cent alcohol in a 100 cc. glass-stoppered cylinder. When the mixture has cleared, withdraw 30 cc. of the alcoholic solution, by means of a pipette, and place it in a 125 cc. Erlenmeyer flask. Neutralize the solution with half-normal potassium hydroxide, using 2 drops of phenolphthalein T.S. as indicator, add 5 cc. of half-normal potassium hydroxide, and heat the mixture on a bath of boiling water under a reflux condenser during one hour. Allow the mixture to cool, remove the flask from the bath, and titrate the excess of alkali with half-normal hydrochloric acid: not less than 4.7 cc. is required for neutralization (*acetins*).

Assay—Proceed as directed for esters under *Oleum Menthæ Piperitæ*, page 957, using 5 cc. of Oil of Lavender, accurately weighed, and 50 cc. of half-normal alcoholic potassium hydroxide. Multiply the number of cc. of half-normal alcoholic potassium hydroxide actually used in the saponification, by 9.811, and divide the product by the weight of the Oil of Lavender taken. The result gives the per cent of esters, calculated as linalyl acetate.

This assay is explained on page 1461.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparations—Linimentum Saponis Mollis; Spiritus Ammoniæ Aromaticus; Spiritus Lavandulæ; Tinctura Lavandulæ Composita; Unguentum Diachylon.

N. F. Preparations—Acetum Aromaticum; Linimentum Ammonii Iodidi; Mistura Ferri Composita (from Spirit); Mistura Oleo-Balsamica; Oleum Hyoscyami Compositum; in all Petroxolins; Spiritus Odoratus.

Uses—It is used as an aromatic and carminative. Dose, one and one-half minims (0.1 cc.).

OLEUM ROSMARINI. U. S. Oil of Rosemary

[Ol. Rosmar.—Rosemary Oil]

The volatile oil distilled from the fresh flowering tops of *Rosmarinus officinalis* Linné (Fam. *Labiatæ*).

Oil of Rosemary yields not less than 2.5 per cent of esters, calculated as bornyl acetate [$C_{10}H_{17}.C_2H_3O_2$], and not less than 10 per cent of total borneol [$C_{10}H_{17}OH$], free and as esters.

This oil consists principally of *pinene*, of the composition $C_{10}H_{16}$, boiling at 165° C., but there is a smaller fraction boiling at from 200° to 210° C., which at low temperatures deposits a camphor, $C_{10}H_{18}O$, identified as borneol. *Cineol* ($C_{10}H_{18}O$) has also been separated from a fraction boiling between 176° and 182° C. The oil is therefore recognized at present as containing d-pinene, camphene, cineol, borneol (10 to 15 per cent), and camphor.

Description and Physical Properties—A colorless or pale yellow liquid, having the characteristic odor of rosemary, and a camphoraceous taste.

Tests for Identity and Purity—The Oil is soluble in 10 volumes of 80 per cent alcohol by volume.

Specific gravity: 0.894 to 0.912 at 25° C.

Optical rotation: varies from 0° to +15° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4660 to 1.4720 at 20° C., page 1525.

A solution of the recently distilled Oil in 80 per cent alcohol (1 in 10) is neutral or only slightly acid to moistened litmus paper.

Assay for Esters—Proceed as directed for esters under *Oleum Menthæ Piperitæ*, page 957, using 10 cc. of Oil of Rosemary. Multiply the number of cc. of half-normal alcoholic potassium hydroxide consumed in the saponification of the Oil by 9.811, and divide the product by the weight of the Oil taken. The result shows the per cent of esters, calculated as bornyl acetate.

Assay for Total Borneol—Proceed as directed for total menthol under *Oleum Menthæ Piperitæ*, page 957, using 10 cc. of Oil of Rosemary. Use the following formula in calculating the per cent of total borneol:

$$\text{Per cent of total borneol} = \frac{A \times 7.710}{B - (A \times 0.021)} \times [1 - (E \times 0.0021)]$$

A is the result obtained by subtracting the number of cc. of half-normal sulphuric acid required in the titration from the number of cc. of half-normal alcoholic potassium hydroxide originally taken, *B* is the weight of the acetylized oil taken, and *E* is the per cent of esters calculated as bornyl acetate.

This assay is explained on page 1461.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparations—Linimentum Chloroformi (from Soap Liniment); Linimentum Saponis; Tinctura Lavandulæ Composita.

N. F. Preparations—Acetum Aromaticum; Linimentum Saponato—Camphoratum; Oleum Hyoscyami Compositum; Spiritus Odoratus.

History—Under the name of *Aqua Reginæ Hungariæ* or *Hungary water*, a spirit made from Rosemary by distillation was very popular several centuries ago.

Uses—It is used chiefly as a local irritant in rubefacient liniments. It may be given in doses of one and one-half minims (0.1 cc.).

THYMUS. N. F. Thyme

[Garden Thyme]

Thyme consists of the dried leaves and flowering tops of *Thymus vulgaris* Linné (Fam. *Labiatæ*). Thyme contains not more than 3 per cent of stems over 1 mm. in diameter or other foreign organic matter, and yields not more than 4 per cent of acid-insoluble ash.

This drug is the source of the official oil of thyme, which is the chief constituent. Tannin and resin are also present.

Description—A low, slender, much-branched, hairy, highly aromatic perennial, the base more or less prostrate and rooting. The leaves are ovate-oblong or linear, revolute on the margin, grayish-green, glandular-punctate on both sides and pubescent beneath, the upper ones bearing in their axils small clusters of whitish or reddish flowers with exserted stamens. The nutlets are about 1 mm. ($\frac{1}{25}$ in.) in diameter, spheroidal, and finely tuberculate. The odor is agreeable, the taste warm, aromatic and pungent.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Thymi.

Uses—As a carminative, emmenagogue, and antispasmodic; doses of one drachm (4 Gm.).

OLEUM THYMI. N. F. Oil of Thyme

(U.S.P. IX)

[**Ol. Thymi**—Thyme Oil]

A volatile oil distilled from the flowering plant of *Thymus vulgaris* Linné (Fam. *Labiatæ*), and containing not less than 20 per cent, by volume, of phenols.

The oil, as prepared in the south of France, is known commercially as *oil of origanum*. It is, after one distillation, of a reddish-brown color, and is called the *red oil*, but when again distilled is colorless, and in this condition is distinguished as the *white oil*. The specific gravity of the red or common oil is stated at 0.905, but probably varies, as the oil is a complex body. The more volatile portion, that coming over below 180° C. (356° F.) in distilla-

tion, is a mixture of *cymene*, $C_{10}H_{14}$, boiling at 175° C. (347° F.), and *pinene*, $C_{10}H_{16}$, boiling at 161° C. (321.8° F.). The less volatile and most valuable portion is *thymol*, $C_{10}H_{14}O$, the stearoptene, a white, crystalline solid, melting at 50° C. (122° F.), and possessing a pungent taste. *Carvacrol*, an isomer of thymol is also present, at times replacing part or all of the thymol, and in addition *linaloöl* and *bornyl acetate* have been found in small amount. This substance is also found in oil of monarda (horsemint). (See Thymol, below.)

Official Description—A colorless or red liquid.
Odor and Taste—Characteristic.
Solubility—Soluble in two volumes of 80 per cent alcohol.
Specific gravity: 0.894 to 0.930 at 25° C.
Tests for Identity—It is slightly lævorotatory.

Shake 1 cc. of the Oil with 10 cc. of hot distilled water, and, after cooling, pass the aqueous layer through a wetted filter: the filtrate does not assume a blue or violet color upon the addition of a drop of ferric chloride T.S.

Assay—Introduce 75 cc. of sodium hydroxide T.S. into a flask with a long graduated neck (cassia flask), add 10 cc. of the Oil to be assayed, stopper the flask tightly, shake the mixture thoroughly, and set it aside for from twelve to twenty-four hours. Then add sufficient sodium hydroxide T.S. to raise the lower limit of the oily layer within the graduated portion of the neck of the flask, and, after the alkaline solution has become clear, adjust it to the temperature at which it was measured, and note the volume of the residual liquid. This measures no more than 8 cc., indicating the presence of not less than 20 per cent by volume, of phenols.

This assay is explained on page 1483.

Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light.

N. F. Preparations—Linimentum Saponato-Camphoratum; Liquor Antisepticus; Mistura Oleo-Balsamica; Oleum Hyoscyami Compositum.

Uses—Oil of thyme is a powerful germicide but is chiefly used in liniments as a stimulant. The official preparations are given above.

THYMOL. U. S. Thymol, Thyme

A phenol [$C_6H_3.CH_3.OH.C_3H_7$ 1:3:4 = 150.16]. It occurs in the volatile oil of *Thymus vulgaris* Linné (Fam. *Labiatæ*) and some other volatile oils.

Preparation—Thymol has been made synthetically and is obtained from the volatile oils of several plants by fractional distillation, by which terpenes are separated. The portion distilling above 190° C. is collected, agitated with solution of sodium hydroxide to separate more of the terpenes, and cooled; the compound of thymol with sodium hydroxide is then decomposed by hydrochloric acid. Thymol is recrystallized from an alcoholic solution. This stearoptene has also been obtained from *Monarda didyma* Linné, *M. punctata* (horsemint), *Ammi copticum*, *Ocymum basilicum*, and *Ptychotis ajowan*.

Description and Physical Properties—Large, colorless, transparent crystals, having an aromatic, thyme-like odor and a pungent, aromatic taste.

One Gm. of Thymol is soluble in about 1000 cc. of water, about 1 cc. of alcohol, 0.7 cc. of chloroform, 1.5 cc. of ether, and in 1.7 cc. of olive oil, at 25° C. It is soluble in glacial acetic acid and in fixed or volatile oils.

Tests for Identity and Purity—Thymol melts between 48° and 51° C., remaining liquid at a considerably lower temperature.

Thymol is heavier than water, but when liquified by fusion it is lighter than water.

An alcoholic solution of Thymol (1 in 20) is neutral to litmus paper, and is optically inactive.

When Thymol is triturated with about an equal weight of camphor or menthol, the mixture liquefies.

Dissolve a very small crystal of Thymol in 1 cc. of glacial acetic acid, and add 6 drops of sulphuric acid and 1 drop of nitric acid: the liquid assumes a deep bluish-green color by reflected light.

Heat about 1 Gm. of Thymol in a test tube in a water bath with 5 cc. of a 10 per cent solution of sodium hydroxide: a clear, colorless, or pale red solution is formed, which becomes darker on standing, without the separation of oily drops. Upon the addition of a few drops of chloroform to this solution and agitating the mixture, a violet color is produced.

Volatilize about 2 Gm. of Thymol on a water bath: not more than 0.05 per cent of residue remains.

N. F. Preparations—Cataplasma Kaolini; Liquor Antisepticus; Liquor Aromaticus Alkalinus; Nebula Aromatica; Nebula Thymolis; Petroxolinum Sulphuratum Compositum; Pulvis Antisepticus.

Uses—Thymol is a powerful germicide; it is chiefly used in mouth washes. It is employed internally as an intestinal antiseptic and vermifuge, especially against the hook-worm. It liquefies, forming an *eutectic solution*, if triturated with an equal amount of chloral hydrate, menthol, or camphor, and some other substances. The dose, as an antiseptic, is two grains (0.125 Gm.); as an anthelmintic, divided into three doses, thirty grains (2 Gm.).

CATARIA. N. F. Catnep

[**Catar.**—CATMINT]

Catnep consists of the dried leaves and flowering tops of *Nepeta Cataria* Linné (Fam. *Labiatæ*).

Catnep contains not more than 5 per cent of its stems over 4 mm. in diameter or other foreign organic matter.

Description—Tops from 10 to 20 cm. long, much branched or crushed and broken; stems quadrangular, downy, up to 4 mm. in diameter; leaves opposite, the larger, petiolate, from 2 to 7 cm. long, ovate or oblong, rounded or heart-shaped at the base, pointed at the apex, pale gray-green, soft-hairy above, downy beneath, margin deeply crenate; floral leaves small, bract-like; flowers small, in dense, interrupted spikes; calyx hairy, tubular, curved obliquely and subequally 5-toothed, corolla whitish, dotted with purple, throat dilated, limb bilabiate, the upper lip erect and two cleft, the lower spreading and three cleft, the middle lobe largest, crenulate; stamens two pairs ascending under the upper lip, lower pair shorter. Odor faintly aromatic and mint-like; taste bitter, pungent and aromatic.

For further description see the N. F. V.

N. F. Preparations—Elixir Catariæ et Fœniculi; Fluidextractum Catariæ.

It contains a volatile oil and tannin.

Uses—Used popularly as a carminative stimulant, diaphoretic and emmenagogue. Dose, one drachm (4 Gm.).

SCUTELLARIA. N. F. Scutellaria

[**Scutell.**—SKULLCAP, HOODWORT, MADWEED]

Scutellaria is the dried over-ground portion of *Scutellaria lateriflora* Linné (Fam. *Labiatæ*).

Scutellaria contains not more than 3 per cent of foreign organic matter.

Description—About 50 cm. long, smooth; stem quadrangular, branched; leaves opposite, petiolate, about 5 cm. long, ovate-lanceolate or ovate-oblong, serrate; flowers in axillary, one-sided racemes, with a pale blue corolla and bilabiate calyx, closed in fruit, the upper lip helmet-shaped, odor slight; taste bitterish. For a further description see the N. F. V.

N. F. Preparations—Fluidextractum Scutellariæ; Tinctura Viburni Opuli Composita.

It contains volatile oil, tannin, and a bitter principle.

Uses—It is used as a tonic and antispasmodic. Dose, fifteen grains (1 Gm.).

Unofficial Plants of the Labiatæ

Brunella Heal-all Self heal	The herb of *B.* (*Prunella*) *vulgaris*. Found in North America, Asia, and Europe
Calamintha Wild Basil	The herb of *C. clinopodium*
Collinsonia Horsebalm	The herb of *Collinsonia canadensis*, grown in North America
Glechoma Ground Ivy	From *G. hederacea* and others, grown in Europe. It contains volatile oil, resin, etc.
Hedeoma American Pennyroyal	The dried leaves and flowering tops of *Hedeoma pulegioides* (Linné) Persoon (Fam. *Labiatæ*). It contains a volatile oil. It is stimulant and aromatic. Dose, two drachms (8 Gm.)
Hyssopus Hyssop	From *H. officinalis*, indigenous to Southern Europe. It contains about ½ per cent of volatile oil, etc.
Lavender	The flowers of *Lavandula vera*. It formerly was official, and contains a volatile oil
Leonurus Motherwort	The herb of *L. cardiaca*, grown in Europe. It contains a volatile oil and a bitter principle
Lycopus Bugleweed	The herb of *L. virginicus*, found in the United States. It contains a volatile oil, resin, etc.
Melissa Balm	The leaves and tops of *Melissa officinalis* Linné

Unofficial Plants of the Labiatæ—*Continued*

Mentha pulegium European Pennyroyal	This plant yields an oil which must not be confounded with the American oil of the same name
Monarda Horsemint	The leaves and tops of *M. punctata*, indigenous to the United States. It contains thymol and a volatile oil, etc.
Rosemary	The leaves of *Rosmarinus officinalis*. It was formerly official, and contains a volatile oil
Salvia Sage	The dried leaves of *Salvia officinalis* Linné (Fam. *Labiatæ*). It contains a terpene, $C_{10}H_{16}$, and an oxygenated portion, *salviol*, $C_{10}H_{18}O$. It is used as a condiment and an *infusion of sage* is used in sore throat. Dose, thirty grains (2 Gm.)

Official Products of the Aromatic Umbelliferæ

The aromatic plants belonging to the family Umbelliferæ are all characterized by the very distinctive properties of the volatile oils obtained by distilling their fruits (sometimes called seeds because of their seed-like appearance) with water. These oils are oxygenated, and are soluble in alcohol. Cumin and dill are unofficial oils which belong to this class.

CARUM. U.S. Caraway

[Caraway Seed, Kümmel, Caraway, Caraway (Seed) Fruit]

Caraway is the dried ripe fruit of *Carum Carvi* Linné (Fam. *Umbelliferæ*).

Caraway contains not more than 3 per cent of other fruits, seeds, or foreign organic matter, and yields not more than 1.5 per cent of acid-insoluble ash.

This fruit, commonly called caraway seed or kümmel, contains about 5 per cent of volatile oil, with a little fixed oil and other constituents.

Description—Oblong, laterally compressed, about 4 or 5 mm. long, usually separated into the two mericarps, which are curved, narrower at both ends, brown, with five yellowish, filiform ribs, and with six oil-tubes. Caraway has an agreeable odor, and a sweetish, spicy taste. For a further description see the U. S. P. X.

U. S. P. Preparation—Tinctura Cardamomi Composita.

Uses—It is used as a carminative and stimulant. Dose, fifteen grains (1 Gm.).

OLEUM CARI. U.S. Oil of Caraway

[Ol. Cari—Caraway Oil]

The volatile oil distilled from the dried ripe fruit of *Carum Carvi* Linné (Fam. *Umbelliferæ*). Oil of Caraway yields not less than 50 per cent by volume of carvone [$C_{10}H_{14}O$ = 150.16].

It consists of two liquid oils of different boiling points and separable by distillation: one a hydrocarbon called *carvene*, $C_{10}H_{16}$, of the specific gravity 0.849 and boiling point 176° C., now recognized as identical with d-limonene, the other the valuable constituent, d-carvone, $C_{10}H_{14}O$, of the sp. gr. 0.9638 and boiling point 224° C. This latter constituent is often extracted from the oil and prepared in a pure state by taking advantage of the formation of a crystalline compound of carvone and hydrogen sulphide, which can then be decomposed by treatment with alcoholic potassium hydroxide.

Sulphides are found in the aqueous distillate which comes over with the oil, as are also several constituents which are ordinarily considered only to accompany destruction distillation products, as methyl alcohol, acetaldehyde, etc.

Description and Physical Properties—A colorless or pale yellow liquid, having the characteristic odor and taste of caraway.

Tests for Identity and Purity—The Oil is soluble in 8 volumes of 80 per cent alcohol, by volume.
Specific gravity: 0.900 to 0.910 at 25° C.
Optical rotation: varies from +70° to +80° in a 100 mm. tube at 25° C., page 1524.
Refractive index: 1.4840 to 1.4880 at 20° C., page 1525.
Oil of Caraway meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

Assay—Place 10 cc. of Oil of Caraway, measured from a pipette, in a 100 cc. cassia flask and add 50 cc. of a saturated solution of sodium sulphite, which has been carefully rendered neutral to 2 drops of phenolphthalein T.S. by means of a 5 per cent sodium bisulphite solution. Heat the mixture in a bath containing boiling water, and shake the flask repeatedly, neutralizing the mixture from time to time by the addition of a few drops of the 5 per cent sodium bisulphite solution. When no coloration appears upon the addition of a few more drops of phenolphthalein T.S. and heating for fifteen minutes, cool to room temperature, and, when the liquids have separated completely, add sufficient sodium sulphite solution to raise the lower limit of the oily layer within the graduated portion of the neck. Note the volume of the residual liquid. This measures not more than 5 cc. indicating the presence of not less than 50 per cent by volume of carvone.

This assay is explained on page 1483.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

N. F. Preparations—Elixir Cardamomi Compositum (from Compound Spirit); Mistura Carminativa; Spiritus Cardamomi Compositus.

Uses—It is a valuable aromatic oil, sometimes called *oil of kümmel*, used in making caraway water and formerly in compound spirit of juniper. Dose, one and one-half minims (0.1 cc.).

FŒNICULUM. N. F. Fennel

(U.S.P. IX)

[**Foenic.**—Fennel Seed]

Fennel is the dried, ripe fruit of cultivated varieties of *Fœniculum vulgare* Miller (Fam. *Umbelliferæ*).

Fennel contains not more than 4 per cent of foreign organic matter.

Description—Oblong, nearly cylindrical, slightly curved, from 4 to 8 mm. long, brownish or greenish-brown; readily separable into the two prominent mericarps, each with five light brown, obtuse ribs, four oil-tubes on the back, and two or four oil-tubes upon the flat face; odor and taste aromatic, anise-like.

For further description see the N. F. V.

N. F. Preparations—Infusum Sennæ Compositum; Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Species Laxativæ; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe.

This fruit contains about 5 per cent of an oxygenated volatile oil, with 10 per cent of fixed oil. It is used as a flavor and to modify the action of purgatives. Dose, fifteen grains (1 Gm.).

OLEUM FŒNICULI. U. S. Oil of Fennel

[**Ol. Fœnic.**—Fennel Oil]

The volatile oil distilled from the dried ripe fruit of *Fœniculum vulgare* Miller (Fam. *Umbelliferæ*). If solid material has separated, carefully warm the Oil until completely liquefied and thoroughly mix it before dispensing.

The property of this oil of solidifying at a low temperature is used in the official test to indicate its purity. Oil of fennel consists of *anethol*, $C_{10}H_{12}O$ (a phenol-ether forming a white solid melting at 21° C. (see *Oleum Anisi*), the latter usually in amounts of about 60 per cent, d-pinene, phellandrene, dipentene, *fenchone*, $C_{10}H_{16}O$ (a liquid ketone), chavicol, anisic aldehyde, and anisic acid. Fenchone is the constituent which when present gives the disagreeable bitter taste to many of the commercial oils. Limonene is also at times present as a constituent. There is reason to believe that much of the commercial oil is adulterated with oil from which the anethol or crystalline constituent has been separated; the official solidifying point, not below 3° C., should be required.

Description and Physical Properties—A colorless or pale yellow liquid, having the characteristic odor and taste of fennel.

Tests for Identity and Purity—The Oil is soluble in 8 volumes of 80 per cent alcohol, by volume, and in 1 volume of 90 per cent alcohol, by volume.

Specific gravity: 0.0953 to 0.0973 at 25° C.
Optical rotation: varies from +12° to +24° in a 100 mm. tube at 25° C., page 1524.
Refractive index: 1.5280 to 1.5380 at 20° C., page 1525.
A solution of the recently distilled Oil in 80 per cent alcohol (1 in 8) is neutral to moistened litmus paper.
The Oil meets the requirements of the test for *heavy metals in volatile oils*, page 1519.
The congealing point of Oil of Fennel does not fall below 3° C. when determined by the method described on page 1524.
Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparations—Aqua Fœniculi; Pulvis Glycyrrhizæ Compositus.
N. F. Preparations—Elixir Anisi; Elixir Catariæ et Fœniculi; Fluidglyceratum Cascaræ Sagradæ Aromaticum; Mistura Carminativa; Syrupus Ficorum Compositus; Syrupus Rhamni Catharticus.

Uses—It is used as a stimulant and flavor, and to overcome flatulence and modify the action of purgatives. The dose is one and one-half minims (0.1 cc.).

CORIANDRUM. N. F. Coriander
(U.S.P. IX)

[**Coriand.**—Coriander Seed]

Coriander is the dried ripe fruit of *Coriandrum sativum* Linné (Fam. *Umbelliferæ*). Coriander contains not more than 5 per cent of other fruits, seeds, or other organic matter and yields not more than 1.5 per cent of acid-insoluble ash, not less than 0.5 per cent of volatile ether-soluble extractive.

Description—Globular; about 4 mm. in diameter; crowned with the calyx-teeth and stylepod, brownish-yellow, with slight, longitudinal ridges; the two mericarps cohering, enclosing a lenticular cavity, and each furnished on the face with two oil-tubes; odor and taste agreeably aromatic.
For further description see the N. F. V.

N. F. Preparations—Fluidextractum Stillingiæ Compositum; Infusum Gentianæ Compositum.

Uses—This fruit furnishes an agreeable aromatic oil. The yield is about 1 per cent. It also contains about 10 per cent of fixed oil. The fruit is seldom used alone, but is often combined with other remedies, chiefly as a flavor. It is also used as a condiment and flavor in cooking. Dose, eight grains (0.5 Gm.).

OLEUM CORIANDRI. U. S. Oil of Coriander

[**Ol. Coriand.**—Coriander Oil]

The volatile oil distilled from the dried ripe fruit of *Coriandrum sativum* Linné (Fam. *Umbelliferæ*).

This is an oxygenated oil, consisting chiefly of a compound, *coriandrol*, $C_{10}H_{18}O$, which boils between 194° and 198° C. Coriandrol is now known as dextrogyrate *linaloöl*. Coriander oil also contains about 5 per cent of dextropinene.

Description and Physical Properties—A colorless or pale yellow liquid, having the characteristic odor and taste of coriander.
Tests for Identity and Purity—The Oil is soluble in 3 volumes of 70 per cent alcohol, by volume.
Specific gravity: 0.863 to 0.875 at 25° C.
Optical rotation: varies from +8° to +13° in a 100 mm. tube at 25° C., page 1524.
Refractive index: 1.4630 to 1.4760 at 20° C., page 1525.
Oil of Coriander meets the requirements of the test for *heavy metals in volatile oils*, page 1519.
Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparations—Elixir Aromaticum (from Spirit); Fluidextractum Cascaræ Sagradæ Aromaticum; Spiritus Aurantii Compositus; Syrupus Sennæ.
N. F. Preparation—Confectio Sennæ; a flavor in emulsions.

Uses—It is used as a carminative and corrective in a dose of one and one-half minims (0.1 cc.).

SUMBUL. N. F. Sumbul
(U. S. P. IX)

[Musk-root]

Sumbul is the rhizome and roots of *Ferula Sumbul* (Kauffmann) Hooker filius or of other closely related species of *Ferula* possessing a characteristic musk-like odor (Fam. *Umbelliferæ*).

Sumbul contains not more than 2 per cent of foreign organic matter.

This Asiatic root contains about ½ per cent of volatile oil and about 10 per cent of a resinous compound having a musky odor.

Description—In transverse segments, varying in diameter from about 2 to 7 cm., and in length from 15 to 30 mm.; light, spongy, annulate or longitudinally wrinkled; bark thin, brown, more or less bristly fibrous; the interior whitish, with numerous brownish-yellow resin-dots and irregular, easily separated fibers; odor strong, musk-like; taste bitter and balsamic

For further description see N. F. V.

N. F. Preparations—Extractum Sumbul; Tinctura Sumbul.

Uses—It is used as a nervine, especially in uterine disorders. Dose, 30 grains (2 Gm.).

ANISUM. N. F. Anise
(U. S. P. IX)

[**Anis.**—Aniseed, Anise Seed, European Aniseed]

Anise is the dried ripe fruit of *Pimpinella Anisum* Linné (Fam. *Umbelliferæ*).

Anise contains not more than 3 per cent of other fruit seeds, or foreign organic matter and yields not more than 1.5 per cent of acid-insoluble ash.

Description—About 4 or 5 mm. long, ovate, compressed at the sides, grayish, finely hairy, and consisting of two mericarps, each with a flat face, and five light brownish, filiform ridges, and about fifteen thin oil-tubes, which can be seen in a transverse section by the microscope. It has an agreeable, aromatic odor, and a sweet, spicy taste.

It may be distinguished from conium fruit (which it somewhat resembles, and which has been mistaken for it) by the odor and taste, and by the conium fruit consisting usually of single mericarps, which are smooth, grooved upon the face, and have crenate ridges with wrinkles between them, and no oil-tubes.

For further description see N. F. V.

N. F. Preparations—Species Laxativæ; Species Pectorales; Tinctura Rhei Dulcis.

Uses—The flavor of this drug is very popular and is usually called licorice flavor by the laity because of the frequent association of the two. This fruit contains about 2 per cent of volatile oil and 3 per cent of fixed oil. It is a useful carminative. Dose, eight grains (0.5 Gm.)

OLEUM ANISI. U. S. Oil of Anise. Oil of Star Anise
[**Ol. Anisi**—Anise Oil]

The volatile oil distilled from the dried ripe fruit of *Pimpinella Anisum* Linné (Fam. *Umbelliferæ*) or from the dried ripe fruit of *Illicium verum* Hooker filius (Fam. *Magnoliaceæ*). The botanical source from which the Oil is derived must be stated on the label. If solid material has separated, carefully warm the Oil until completely liquefied, and mix it thoroughly before dispensing.

Oil of Illicium (*Star Anise*) has the same properties as the oil from *Pimpinella Anisum*. It consists of a small quantity of terpene, $C_{10}H_{16}$, but mainly of *anethol*, parapropenylanisol, $C_6H_4C_3H_5OCH_3$ (about 85 per cent), which is present, however, in two isomeric modifications, one solid at ordinary temperatures and heavier than water (*solid anethol*), the other liquid and more volatile (*estragol* or *methyl chavicol*). *Anethol*, both in the liquid and in the solid form, is present, and is the chief constituent of the oils of *anise*, *star anise*, and *fennel*. The solidification test of the U. S. P. is based upon the anethol content. By oxidation, by means of nitric acid, or chromic anhydride, the different forms of anethol yield *anisic acid*, $C_8H_8O_3$. Oil of anise, by exposure to air, is oxidized, with the formation of *anisic aldehyde*, *acetic aldehyde* and *anisic acid*, and becomes less disposed to congeal.

Description and Physical Properties—A colorless or pale yellow, strongly refractive liquid, having the characteristic odor and taste of anise.

Tests for Identity and Purity—The Oil is soluble with not more than a slight cloudiness in 3 volumes of 90 per cent alcohol, by volume.

Specific gravity: 0.978 to 0.988 at 25° C.

Optical rotation: varies from +1° to −2° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.5440 to 1.5600 at 20° C., page 1525.

A solution of the recently distilled Oil in 90 per cent alcohol (1 in 3) is neutral to moistened litmus paper, and develops no blue or brownish color upon the addition of 1 drop of ferric chloride T.S. to 5 cc. of the solution (*phenols*).

The Oil meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

The congealing point of Oil of Anise does not fall below 15° C., as determined by the method described on page 1524.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparations—Aqua Anisi; Elixir Aromaticum (from Spirit); Fluidextractum Cascaræ Sagradæ Aromaticum; Spiritus Anisi; Spiritus Aurantii Compositus; Syrupus Sarsaparillæ Compositus; Tinctura Opii Camphorata.

N. F. Preparations—Elixir Phosphori; Syrupus Trifolii Compositus; Tinctura Gambir Composita.

Uses—Oil of Anise is usually shipped in lead vessels and sometimes becomes contaminated with that metal; hence the U. S. P. test for heavy metals in this oil. Oil of anise is given as a carminative in the dose of one and one-half minims (0.1 cc.). It is also a valuable flavoring agent, often associated with licorice.

ANETHOL. N. F. Anethol

The methyl ether of para-propenyl phenol [$C_6H_4.C_3H_5.OCH_3$ = 148.15]. It is the main constituent in the oils of anise, star anise, and fennel, and is usually obtained from these by fractionating, chilling and crystallizing.

Official Description—A colorless or faintly yellow, highly refractive liquid at a temperature of 23° C. or above, having a sweet taste and the aromatic odor of anise. At from 20° to 21° C. it solidifies to a white, glistening, crystalline mass which melts at from 22° to 23° C.

Solubility—Almost insoluble in water; readily soluble in ether or chloroform, and forms a clear solution with two volumes of alcohol.

Specific gravity: 0.984 to 0.986 at 25° C.

Tests for Identity and Purity—Boiling point: 235° to 236° C.

Refractive index: 1.558 to 1.561 at 25° C.

It is optically inactive or shows a deviation of not more than 0.08° in a 100 mm. tube at 25° C. due to slight traces of the oil from which the Anethol has been prepared (if prepared from oil of anise, this deviation will be lævorotatory, if from oil of fennel, dextrorotatory).

Aldehydes—Shake 10 cc. of Anethol with 50 cc. of a saturated aqueous solution of sodium bisulphite in a graduated cylinder and allow the mixture to stand for six hours. No appreciable diminution in the volume of Anethol will be observed nor does a crystalline deposit separate.

Preserve in well-stoppered, amber-colored bottles, protected from light and air.

N. F. Preparations—Elixir Anisi; Elixir Cardamomi Compositum (from Compound Spirit of Cardamom); Pulvis Rhei et Magnesiæ Anisatus; Spiritus Ammoniæ Anisatus; Spiritus Cardamomi Compositus.

Uses—Its uses are similar to those described under Oil of Anise. It is frequently sold as *Synthetic* or *Artificial Oil of Anise*.

Average dose—3 minims (0.2 cc.).

ANGELICÆ FRUCTUS. N. F. Angelica Fruit

[**Angel Fruct.**—Angelica Seed, European Angelica Seed]

Angelica fruit is the dried ripe fruit of *Angelica Archangelica* Linné and of other species of *Angelica* (Fam. *Umbelliferæ*).

Angelica Fruit contains not more than 3 per cent of foreign fruits, seeds or other foreign organic matter.

Description—The fruit is oval, about 3 to 5 mm. long, dorsally compressed, of a brown color, and separates when ripe into 2 mericarps, which are flat upon the face and somewhat convex upon the back, the 3 dorsal ribs filiform and rather sharply keeled, while the 2 lateral ones are extended into a broad light-colored membranous margin; oil-tubes 6; odor and taste strong, resembling those of caraway.

For further description see N. F. V.

N. F. Preparations—Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Tinctura Antiperiodicæ; Tinctura Antiperiodicæ sine Aloe.

Uses—It is used as an aromatic in doses of fifteen grains (1 Gm.).

ANGELICÆ RADIX. N. F. Angelica Root

[**Angel. Rad.**—GARDEN ANGELICA ROOT, ARCHANGEL]

Angelica Root consists of the dried rhizome and roots of *Angelica Archangelica* Linné and of other species of *Angelica* (Fam. *Umbelliferæ*).

Angelica Root contains not more than 5 per cent of its stem bases or other foreign organic matter and yields not more than 4 per cent of acid insoluble ash.

Description—A short, thick root-stock, which is closely annulated above, and below abruptly divided into a large number of nearly simple branches, which are about 6 mm. thick and 15 cm. or more long, longitudinally wrinkled, of a dark brown color externally, yellowish inside, with a spongy, radiated meditullium and numerous shining resin-cells in the thick bark. It has a strong aromatic odor and a sweetish, pungently aromatic and bitter taste, and breaks with a smooth, somewhat waxy fracture. The roots frequently come braided into fanciful forms.

For a further description see N. F. V.

N. F. Preparation—Fluidextractum Angelicæ Radicis.

Uses—It is used as an aromatic and emmenagogue in doses of thirty grains (2 Gm.).

APII FRUCTUS. N. F. Celery Fruit

[**Apii. Fruct.**—CELERY SEED]

Celery Fruit is the dried ripe fruit of *Apium graveolens* Linné (Fam. *Umbelliferæ*).

Description—Celery Fruit contains not more than 5 per cent of unsound or foreign fruit or other foreign organic matter and yields not more than 3 per cent of acid-insoluble ash.

It is about 1 to 1.5 mm. long, roundish-ovate, laterally flattened, brown, with lighter-colored ribs and smooth; the mericarps are usually separate, somewhat curved, flat on the face, and contain about 12 thin oil-tubes; odor and taste agreeably aromatic. The fruit yields 2 or 3 per cent of a colorless volatile oil, having the characteristic odor and taste of the plant, and small quantities of *apiol*.

For further description see N. F. V.

N. F. Preparation—Fluidextractum Apii Fructus.

Uses—Used as a condiment and medicinally as a nerve sedative. The dose is thirty grains (2 Gm.).

Unofficial Volatile Oils and Plants of the Umbelliferæ

Anethum Graveolens Dill	An umbelliferous fruit, indigenous to Southern Europe. The herb is used in flavoring the variety of salt pickles which bear the name "*dill pickles*"
Oleum Anethi Oil of Dill	An oxygenated oil. The yield is about 4 per cent
Carota Carrot Fruit	The fruit of *Daucus Carota*, indigenous to Northern Asia
Oil of Carrot	An oxygenated oil
Cicuta Water Hemlock	The herb of *Cicuta virosa*, found in Northern Canada
Cuminum Cumin	The fruit of *Cuminum Cyminum*, indigenous to Egypt
Oil of Cumin	Consists of several hydrocarbons. The yield is about ¼ per cent
Heracleum Cow Parsnip (Masterwort)	From *Heracleum lanatum*, grown in the United States. It contains a volatile oil, resin, etc.
Levisticum Lovage	The root of *Levisticum officinale*, indigenous to Southern Europe. It contains soft and pungent resins
Phellandrium Water Fennel	The fruit of *Œnanthe Phellandrium*, grown in Europe. It contains about 1½ per cent of volatile oil and resins

Official Products from the Lauraceæ

CINNAMOMUM. U. S. Cinnamon

[**Cinnam.**—CINNAMOMUM SAIGONICUM U. S. P. IX, TRUE CINNAMON, SAIGON CINNAMON, SAIGON CASSIA]

Cinnamon is the dried bark of *Cinnamomum Loureirii* Nees (Fam. *Lauraceæ*).

Cinnamon yields not less than 2 per cent of volatile ether-soluble extractive.

Description—In quills about 15 cm. long, and 10 to 15 mm. in diameter, the bark 2 or 3 mm. thick; outer surface gray or light grayish-brown with whitish patches, more or less wrought from numerous warts and some transverse ridges and fine longitudinal wrinkles; the inner surface cinnamon-brown or dark brown, granular and slightly striate; fracture short, granular, in the outer layer cinnamon-colored, having near the cork numerous whitish striæ forming an almost uninterrupted line; odor fragrant; taste sweet, warmly aromatic, somewhat astringent.

Assay—Proceed as directed under volatile ether-soluble extractive, page 1523.

Preserve in tightly-closed containers.

For a further description see the U. S. P. X.

U. S. P. Preparations—Tinctura Cardamomi Composita; Tinctura Gambir Composita; Tinctura Lavandulæ Composita; Tinctura Rhei Aromatica.

N. F. Preparations—Elixir Taraxaci Composita (from Tincture); Mistura Rhei Alkalina (from Tincture); Pulvis Aromaticus; Pulvis Aromaticus Rubefaciens; Pulvis Cretæ Aromaticus; Syrupus Cinnamomi; Syrupus Sennæ Aromaticus; Tinctura Antiperiodicæ; Tinctura Antiperiodicæ sine Aloe; Tinctura Aromatica; Tinctura Cinnamomi; Tinctura Opii Crocata; Tinctura Viburni Opuli Composita.

Uses—Cinnamon owes its virtue to a volatile oil. There are also present tannin, mannite, mucilage, sugar, etc. The tannin present often causes a fluidextract of cinnamon to gelatinize through its alteration. It is used chiefly as a vehicle, also as a local stimulant and mild astringent in certain types of diarrhea in doses of four grains (0.25 Gm.) and also as a flavor.

OLEUM CINNAMOMI. U. S. Oil of Cinnamom

[**Ol. Cinnam.**—OLEUM CASSIÆ U. S. P. IX]

The volatile oil distilled from the leaves and twigs of *Cinnamomum Cassia* (Linné) Blume (Fam. *Lauraceæ*), rectified by steam distillation. Oil of Cinnamon yields not less than 80 per cent by volume of cinnamic aldehyde [C_9H_8O].

Description and Physical Properties—A yellowish or brownish liquid, becoming darker and thicker by age or exposure to the air, and having the characteristic odor and taste of cassia cinnamon.

Tests for Identity and Purity—The Oil is soluble in an equal volume of alcohol, in 2 volumes of 70 per cent alcohol, by volume, and in an equal volume of glacial acetic acid.

Specific gravity: 1.045 to 1.063 at 25° C.

Optical rotation: varies from +1° to −1° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.6020 to 1.6060 at 20° C., page 1525.

A solution of the recently rectified oil in 70 per cent alcohol (1 in 2) is slightly acid to moistened blue litmus paper.

The Oil meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

Shake 2 cc. of the Oil in a test tube with from 5 to 10 cc. of purified petroleum benzin, allow the liquids to separate, and decant the benzin layer into another test tube: this liquid is but slightly colored, and does not assume a green color upon shaking with an equal volume of copper acetate solution (1 in 1000) (*rosin or rosin oils*).

Rinse the interior surface of a well-cleaned, 1000 cc. beaker with distilled water, and pass the washings through a small filter until the addition of 1 drop of silver nitrate T.S. to a portion of the filtrate, acidulated with 1 drop of nitric acid, shows no turbidity. Place 3 or 4 drops of the Oil on a clean watch glass supported on a triangle, ignite, and immediately cover with the moistened beaker. Wash the products of combustion from the sides of the beaker through the washed filter with from 10 to 20 cc. of distilled water, and acidulate the filtrate with 1 drop of nitric acid; the addition of 1 drop of silver nitrate T.S. produces no turbidity (*chlorinated products*).

Assay—Proceed as directed under *Oleum Cari*, page 965, using 10 cc. of Oil of Cinnamon, measured from a pipette. The volume of the residual oily layer measures not more than 2 cc., indicating the presence of not less than 80 per cent by volume of cinnamic aldehyde.

For a description of this assay see page 1483.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparations—Acidum Sulphuricum Aromaticum; Aqua Cinnamomi; Fluidextractum Cascaræ Sagradæ Aromaticum; Infusum Digitalis (from Water); Mistura Cretæ (from Water); Spiritus Cinnamomi; Syrupus Rhei (from Spirit).

N. F. Preparations—Acetum Aromaticum; Dentifricium; Elixir Cardamomi Compositum (from Compound Spirit); Elixir Vanillini Compositum (from Compound Spirit); Fluidglyceratum Cascaræ Sagradæ Aromaticum; Lavatio Ori; Liquor Pepsini Aromaticus; Mistura Oleo-Balsamica; Nebula Aromatica; Nebula Mentholis Composita; Odontalgicum Oleum Ricini Aromaticum; Spiritus Cardamomi Compositus; Spiritus Vanillini Compositus; Syrupus Ipecacuanhæ et Opii (from Spirit); Syrupus Rhamni Catharticæ.

There are two oils of cinnamon in commerce: one procured from the Ceylon cinnamon, the other from the Chinese cinnamon. The latter (*oil of cassia*) is now the only official one. The Chinese cinnamon is much the cheaper and more abundant of the two and will probably continue to be generally employed, notwithstanding the fact that the Ceylon product has the finer flavor. The value of cassia oil depends upon the percentage of cinnamic aldehyde which it contains. Cinnamyl acetate and cinnamic acid are also present, as well as small amounts of phenyl propyl acetate and orthocumaric aldehyde. In the oil of Ceylon cinnamon, cinnamic aldehyde is the chief constituent, but eugenol is present to the extent of over 5 per cent, and phellandrene has also been reported. Cinnamon leaf oil contains much eugenol and very little cinnamic aldehyde, safrol and benzaldehyde being present as minor constituents. Moderate oxidation of the oil yields the corresponding cinnamic acid, $C_9H_8O_2$, but by more energetic oxidation yields benzoic acid, $C_7H_6O_2$.

Oil of Ceylon cinnamon has a slightly acid reaction. Specific gravity between 1.024 and 1.040. It is readily soluble in alcohol, and contains between 65 and 75 per cent of cinnamic aldehyde and from 4 to 8 per cent of eugenol. When cooled to $-10°$ C. it remains clear, but at a lower temperature a solid portion separates from it. *Oil of Chinese cinnamon* (oil of cassia) has similar properties, the marked difference being that its specific gravity is between 1.045 and 1.063, the aldehyde content being 80 per cent or above, and that it contains no eugenol. The odor and taste are not quite so agreeable as that of the Ceylon variety.

Oil of Ceylon cinnamon when not very fresh contains cinnamic acid in sufficient quantity to give a permanent cloudiness to cinnamon water made from it. Dose, one minim (0.05 cc.).

Cinnamic Aldehyde (C_9H_8O), known as *Synthetic Oil of Cassia*, was official in the U. S. P. VIII, but has not been admitted to subsequent revisions. It was described as an aldehyde obtained from Oil of Cinnamon or prepared synthetically, containing not less than 95 per cent of pure cinnamic aldehyde [$C_6H_5.CH:CH.COH$]. It is nearly identical with the oil distilled from Cassia Cinnamon, and should be kept in small, amber-colored, well-stoppered bottles. This liquid is found in both oil of cassia and oil of Ceylon cinnamon, and can be separated by treatment with solution of sodium sulphite. It may also be made synthetically by saturating a mixture of acetaldehyde and benzaldehyde with hydrochloric acid gas. It is a colorless liquid. Optically inactive, with a cinnamon-like odor and a burning, aromatic taste. The specific gravity is about 1.047 at 25° C. Sparingly soluble in water, miscible in all proportions with alcohol, ether and fixed and volatile oils. It boils at about 250° C. with partial decomposition. Cinnamic aldehyde should partially solidify when the temperature is reduced by a freezing mixture of ice and salt, and should melt again at $-7.5°$C. If the looped end of a piece of clean copper wire be held in a non-luminous flame until it glows, then cooled, and the loop dipped into cinnamic aldehyde, ignited, and held so that the liquid burns outside of the flame, then if the loop be slowly brought in contact with the lower outer edge of the flame, no green tinge should be discernible (*chlorinated products*). It may be assayed as directed under oil of cinnamon. Cinnamic aldehyde is often used to replace oil of cassia as a flavor.

Uses—Oil of cinnamon is used as a flavor and to modify the action of griping or drastic drugs. Also used in flatulent colic. Dose, one to three minims (0.06 to 0.2 cc.). Like oil of anise this oil is usually shipped in lead vessels from China and a test for heavy metals is therefore necessary.

Official Products from the Myrtaceæ

CARYOPHYLLUS. U. S. Clove

[Caryoph.—Cloves]

Clove is the dried flower-buds of *Caryophyllus aromaticus* Linné (Fam. *Myrtaceæ*).

Clove contains not more than 5 per cent of its stems and not more than 1 per cent of other foreign organic matter, and yields not less than 15 per cent of volatile ether-soluble extractive, not more than 10 per cent of crude fiber, and not more than 0.75 per cent of acid-insoluble ash.

Description—About 15 mm. long, dark brown, consisting of a subcylindrical solid and glandular calyx-tube, terminated by four teeth, and surmounted by a globular head, formed by four petals, which cover numerous curved stamens, and one style. Clove emits oil, when scratched, and has a strong, aromatic odor, and a pungent, spicy taste.

Assay—Proceed as directed under volatile ether-soluble extractive, page 1523.

For further description see the U. S. P. X.

U. S. P. Preparations—Tinctura Lavandulæ Composita; Tinctura Rhei Aromatica.

N. F. Preparations—Pulvis Aromaticus Rubefaciens; Pulvis Cretæ Aromaticus; Pulvis Myrciæ Compositus; Syrupus Sennæ Aromaticus; Tinctura Aromatica; Tinctura Opii Crocata; Tinctura Viburni Opuli Composita.

Clove contains about 16 per cent of volatile oil, 10 per cent of tannin, *Caryophyllin*, $C_{10}H_{16}O$, a crystalline principle, and *eugenin*, $C_{10}H_{12}O_2$, also crystalline.

Uses—It is used as an aromatic in doses of four grains (0.25 Gm.).

OLEUM CARYOPHYLLI. U. S. Oil of Clove

[Ol. Caryoph.—Clove Oil, Oil of Cloves]

The volatile oil distilled from the dried flower-buds of *Caryophyllus aromaticus* Linné (Fam. *Myrtaceæ*). Oil of Clove yields not less than 82 per cent by volume of eugenol [$C_{10}H_{12}O_2 = 164.15$].

Oil of clove, when recently distilled, is a thin fluid, clear, and colorless, but becomes yellowish by exposure, and ultimately reddish-brown. Oil of clove contains small amounts of vanillin, methyl alcohol, and furfurol, but is mainly composed of an unsaturated phenol termed eugenol, which is now an official product, and its acetic derivative (see *Eugenol*), and a sesquiterpene, *caryophyllene*. Eugenol acetyl salicylate has also been reported. The U. S. P. contains an assay process for the eugenol content. *Eugenol* has been shown to be the methyl ether of allyldioxybenzene,

$$C_6H_3\begin{cases} C_3H_5 \\ OCH_3 \\ OH \end{cases}$$

. One of its most important reactions is its conversion into *vanillin*. For this purpose it is boiled with acetic anhydride, whereby *aceteugenol* is formed, which, oxidized in weak acid solution by potassium permanganate, yields *acetvanillic acid*, and this with weak potassium hydroxide solution is changed into vanillin, which is then extracted by acidifying and shaking up with ether. The characteristic aromatic odor of oil of clove is due to *methylamylketone*, $CH_3.CO.C_5H_{11}$, which has been found to be present only in minute quantity. The proportion of eugenol in oil of clove is regarded as an index of the quality of the oil (see official assay below).

Description and Physical Properties—A colorless or pale yellow liquid, becoming darker and thicker by age or exposure to the air, and having the characteristic odor and taste of clove.

Tests for Identity and Purity—The Oil is soluble in 2 volumes of 70 per cent alcohol, by volume.
Specific gravity: 1.038 to 1.060 at 25° C.
Optical rotation: does not exceed −1° 10′ in a 100 mm. tube at 25° C., page 1524.
Refractive index: 1.5300 to 1.5350 at 20° C., page 1525.
The Oil meets the requirements of the test for *heavy metals in volatile oils*, page 1519.
A solution of the recently distilled Oil in 70 per cent alcohol (1 in 2) is slightly acid to moistened blue litmus paper.
Shake 1 cc. of the Oil with 20 cc. of hot distilled water; the water shows not more than a scarcely perceptible acid reaction with blue litmus paper. Cool the mixture and pass the aqueous layer through a wetted filter: the clear filtrate, with 1 drop of ferric chloride T.S., yields only a transient, grayish-green color, but not a blue or violet color (*phenol*).
Assay—Place 10 cc. of Oil of Clove, measured from a pipette, in a 100 cc. cassia flask, add 50 cc. of potassium hydroxide T.S., shake the mixture for five minutes, and heat it for ten minutes in a bath containing boiling water. Remove it from the bath, and cool to room temperature. When the liquids have separated completely, add sufficient potassium hydroxide T.S. to raise the lower limit of the oily layer within the graduated portion of the neck, and note the volume of the residual liquid. This measures not more than 1.8 cc., indicating the presence of not less than 82 per cent by volume of eugenol.
This assay is explained on page 1483.
Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

N. F. Preparations—Acetum Aromaticum; Dentifricium; Elixir Cardamomi Compositum (from Compound Spirit); Fluidglyceratum Cascaræ Sagradæ Aromaticum; Lavatio Ori; Liquor Pepsini Aromaticus; Nebula Aromatica; Oleum Ricini Aromaticum; Spiritus Cardamomi Compositus; Syrupus Eriodictyi Aromaticus.

Uses—Oil of clove is a powerful germicide but is too irritant for most purposes. It is largely used as a remedy for toothache. It produces relief if the pain is caused by an exposed dentine, and may be used by applying a little upon cotton to the affected tooth. Dose, one and one-half minims (0.1 cc.).

EUGENOL. U. S. Eugenol

[Synthetic Oil of Cloves]

A phenol [$C_6H_3.C_3H_5.OCH_3.OH$ 1:3:4 = 164.15] obtained from clove and other sources.

Preparation—Eugenol is found in the volatile oils from clove, pimenta, bay leaves, Ceylon cinnamon, camphor, sassafras, massoy bark, canella, culilawan and others. It is principally obtained, however, from oil of clove. It may be made by treating oil of clove with an excess of solution of sodium hydroxide and shaking the mixture with ether to remove terpenes. The aqueous solution of sodium eugenol is decomposed by hydrochloric acid, and the eugenol purified by repeated washing.

Description and Physical Properties—A colorless or pale yellow, thin liquid, having a strongly aromatic odor of clove and a pungent, spicy taste. Exposure to air causes it to become darker and thicker.
Eugenol is slightly soluble in water, but is miscible with alcohol, chloroform, ether, and with fixed oils. It is soluble in twice its volume of 70 per cent alcohol.
Specific gravity: 1.064 to 1.070 at 25° C.
Tests for Identity and Purity—Eugenol boils between 250° and 255° C.
It is optically inactive and strongly refractive.
A mixture of 1 cc. of Eugenol and 20 cc. of hot distilled water is only very slightly acid to litmus paper.
Dissolve 1 cc. of Eugenol in 12 cc. of sodium hydroxide T.S., and add 18 cc. of distilled water: a clear solution results which becomes turbid when exposed to air (*hydrocarbons*).
Shake 1 cc. of Eugenol with 20 cc. of distilled water, filter, and add 1 drop of ferric chloride T.S. to 5 cc. of the clear filtrate; a transient grayish-green color, but not a blue or violet color, is produced (*phenol*).
Preserve in well-stoppered containers, in a cool place, protected from light.

N. F. Preparation—Mistura Oleo-Balsamica.

Uses—Eugenol is used extensively to replace oil of clove. It is also used by dentists, for its disinfectant action. in filling root canals. The dose is one and one-half minims (0.1 cc.).

OLEUM MYRCIÆ. N. F. Oil of Myrcia

[Ol. Myrc.—Oil of Bay]

A volatile oil distilled from the leaves of *Pimenta acris* (Swartz) Kostel (Fam. *Myrtaceæ*).

Official Description—A yellow or brownish-yellow liquid.

Odor, Taste and Reaction—A pleasant, aromatic odor and a pungent, spicy taste. An alcoholic solution is slightly acid to litmus paper.

Solubility—With an equal volume of alcohol, glacial acetic acid, or carbon disulphide, it yields slightly turbid solutions.

Specific gravity: 0.962 to 0.990 at 25° C.

Tests for Identity and Purity—It is lævorotatory, the angle of rotation not exceeding −3°, in a 100 mm. tube, at 25° C.

When mixed with an equal volume of a concentrated solution of sodium hydroxide, it forms a semi-solid mass.

Dissolve 2 drops of the Oil in 4 cc. of alcohol, and add a drop of ferric chloride T.S.: a light green color is produced. If the same test is made with a drop of dilute ferric chloride T.S., prepared by diluting the test solution with four times its volume of distilled water, a light bluish coloration is produced, which soon disappears.

Shake 1 cc. of the Oil with 20 cc. of hot distilled water and filter: the filtered aqueous solution does not give more than a scarcely perceptible acid reaction with litmus paper and on adding a drop of ferric chloride T.S. it yields only a transient, grayish-green but not a blue or violet color (*phenol*).

Preserve in small, well-stoppered, amber-colored bottles, in a cool place, protected from light.

N. F. Preparation—Spiritus Myrciæ Compositus.

Uses—A perfume, used chiefly in the preparation of *Bay Rum*. (See page 313.)

PIMENTA. N. F. Pimenta

[Piment.—Allspice]

Pimenta is the dried, nearly ripe fruit of *Pimenta officinalis* Lindley (Fam. *Myrtaceæ*).

Pimenta contains not more than 3 per cent of foreign organic matter and not more than 0.4 per cent of acid-insoluble ash.

Description—About 5 mm. in diameter, nearly globular, crowned with the short, four-parted calyx or its remnants, and a short style; brownish or brownish-gray, granular and glandular, two-celled; each cell containing one brown, plano-convex, roundish-reniform seed; odor and taste pungently aromatic, clove-like.

For further description see N. F. V.

N. F. Preparation—Tinctura Guaiaci Composita.

Uses—This aromatic fruit contains about 3 per cent of volatile oil, with tannin, fat, resin, gum, sugar, etc. It is used chiefly in medicine as an adjuvant to tonics and purgatives. The dose is fifteen grains (1 Gm.).

OLEUM PIMENTÆ. N. F. Oil of Pimenta

(U. S. P. IX)

[Ol. Piment.—Pimento Oil, Oil of Allspice]

A volatile oil distilled from the fruit of *Pimenta officinalis* Lindley (Fam. *Myrtaceæ*), yielding not less than 65 per cent, by volume, of eugenol [$C_{10}H_{12}O_2$ = 164.15].

Official Description—A colorless, yellow or reddish liquid, becoming darker with age.

Odor and Taste—Characteristic odor and taste of allspice.

Solubility—Soluble in an equal volume of 90 per cent alcohol; also soluble in 2 volumes of 70 per cent alcohol.

Specific gravity: 1.018 to 1.048 at 25° C.

Tests for Identity and Purity—The optical rotation varies from 0° to −4° in a 100 mm. tube at 25° C.

Assay—Introduce 10 cc. of the oil into a flask with a long graduated neck (cassia flask), add 50 cc. of potassium hydroxide T.S., shake the mixture for five minutes, and then heat it on a water bath during ten minutes, cool, and when the liquids have separated completely add sufficient potassium hydroxide T.S. to raise the lower limit of the oily layer within the graduated portion of the neck, and note the volume of the residual liquid. The residual liquid measures not more than 3.5 cc. indicating the presence of not less than 65 per cent by volume, of eugenol.

An explanation of this assay will be found on page 1483.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

N. F. Preparations—Liquor Pepsini Aromaticus; Spiritus Myrciæ Compositus.

Uses—The oil is used as a stimulant and carminative in doses of three minims (0.2 cc.).

VANILLA. N. F. Vanilla

[Vanill.—Vanilla Bean]

Vanilla is the cured, full-grown, unripe fruit of *Vanilla planifolia* Andrews (Fam. *Orchidaceæ*).

This valuable drug contains a trace of a volatile oil, 10 per cent of fixed oil, resin, sugar, etc., and *vanillin*. $C_8H_8O_3$, which is the aldehyde of methylprotocatechuic acid, and is now official (see page 977).

The agrecable odor and taste of " vanilla bean " is due to a fermentation occurring during the curing process; the fruit when first plucked from the plant has little odor or taste.

Description—From 15 to 35 cm. long, and about 8 mm. thick, linear, narrowed and bent or hooked at the base, rather oblique at the apex, wrinkled, somewhat warty, dark brown, glossy-leathery, one-celled, and containing a blackish-brown pulp, with numerous, minute seeds, and more or less acicular crystals; odor and taste peculiar, fragrant.

For further description see N. F. V.

N. F. Preparations—Elixir Ammonii Valeratis (from Tincture); Syrupus Bromidorum; Tinctura Vanillæ.

Uses—It is used as a flavor.

Flavoring Extracts—A brief review of the legal requirements for other flavoring extracts will be found in a footnote[1].

---

[1] **Flavoring Extracts**

Flavoring Extracts—By tradition, training, and experience the pharmacist is peculiarly well fitted to manufacture and dispense flavoring extracts. Before the passage of the Food and Drugs Act the flavoring extracts obtainable at the average pharmacy were far superior to similar products procurable at the average grocery. That this condition is no longer true is no reflection upon the quality of the extracts made by the pharmacist, but is an evidence of the effectiveness of legislation in improving the quality of commercial products made upon a large scale. Substandard or adulterated flavoring extracts are now rarely reported in the lists of products upon which prosecutions are based for violation of food laws.

According to the definition given by the U. S. Department of Agriculture in Circular 136, entitled *Standards of Purity for Food Products, a Flavoring Extract is a solution in ethyl alcohol of proper strength, of the sapid and odorous principles derived from an aromatic plant or parts of the plant, with or without its coloring matter, and conforms in name to the plant used in its preparation.*

The strengths of flavoring extracts as established in this list of standards are given below:

The volatile oil extracts, made by dissolving the proper amount of the volatile oil in alcohol of appropriate concentration, are of the following strengths:

Almond	1 per cent of oil of almond, free from hydrocyanic acid	Peppermint	3 per cent of oil of peppermint
Anise	3 per cent of oil of anise	Rose	0.4 per cent of oil of rose
Celery	0.3 per cent of oil of celery	Savory	0.35 per cent of oil of savory
Cassia	2 per cent of oil of cassia	Spearmint	3 per cent of oil of spearmint
Cinnamon	2 per cent of oil of cinnamon	Star Anise	3 per cent of oil of star anise
Clove	2 per cent of oil of clove	Sweet Basil	0.1 per cent of oil of sweet basil
Lemon	5 per cent of oil of lemon	Sweet Marjoram	1 per cent of oil of sweet marjoram
Lemon (terpeneless)	0.2 per cent of terpeneless oil of lemon	Thyme	0.2 per cent of oil of thyme
Nutmeg	2 per cent of oil of nutmeg	Wintergreen	3 per cent of oil of wintergreen
Orange	5 per cent of oil of orange		
Orange (terpeneless)	0.2 per cent of terpeneless oil or orange		

The extracts made directly from the plant materials are as follows:

Ginger	Must contain in each 100 cc. the alcohol soluble matters from not less than 20 Gm. of ginger
Tonka	Prepared from tonka bean, with or without sugar or glycerin, and containing not less than 0.1 per cent of coumarin, together with the soluble constituents of the tonka bean
Vanilla	Prepared from vanilla bean, with or without sugar or glycerin, and containing in 100 cc. the soluble matters from not less than 10 Gm. of vanilla bean.

The standards quoted above for ginger and vanilla extracts are in conformity with the standards for Tincture of Ginger U. S. P. and Tincture of Vanilla N. F., respectively. A ruling of the Federal Prohibition Director makes the sale of U. S. P. Tincture of Ginger illegal except upon prescription; double strength tincture was for a time permitted to be sold under this regulation. This is complicated in some states by the fact that no preparation of ginger may legally be sold unless it be of U. S. P. strength. In Pennsylvania no Tincture of Ginger sales whatever are legal, as this is one of the states in which such legislation has been passed.

In labeling flavoring extracts care must be taken to avoid such descriptive terms as " concentrated," " double strength," etc., unless they are actually true. Extracts which are not of full standard strength must be labeled correctly as " half strength " or whatever they happen to be. Extracts which are not made from the genuine flavoring materials in any particular case must be labeled " imitation " or " substitute". A vanilla extract which contains added vanillin, tonka, or coumarin, may not be labeled " vanilla compound, but must be labeled, " imitation vanilla " or " vanilla substitute". Any other method of labeling is in violation of the law and subjects the seller to the risk of prosecution.

VANILLINUM. U.S. Vanillin

[Vanillin.—Vanilla Crystals]

Methylprotocatechuic aldehyde [$C_6H_3.CHO.OCH_3.OH$ 1:3:4 = 152.10].

Preparation—Vanillin may be obtained from vanilla, which contains from 2 to 3 per cent. It is also found in many substances, and in the tissues of certain plants, in crude beet sugar, asparagus, and even in asafetida. The vanillin of commerce is made artificially, and, while chemically identical with the product obtained from the "vanilla bean", owing to the fact that the vanilla contains other odorous products, "flavoring preparations", made from vanillin, never equal in flavor the preparation in which vanilla alone is used. Vanillin is made synthetically by oxidizing either coniferin or eugenol, by treating guaiacol with chloroform in the presence of an alkali, and by other methods. It is frequently adulterated. Some of the substances which have been detected are acetanilid, boric acid, benzoic acid, sugar, and coumarin.

Description and Physical Properties—Fine, white, or only very slightly yellowish, needle-like crystals, having an odor and taste resembling vanilla.

One Gm. of Vanillin is soluble in 100 cc. of water and in about 20 cc. of glycerin, at 25° C. One Gm. is soluble in 16 cc. of water at 80° C. It is freely soluble in alcohol, chloroform, and ether.

Tests for Identity and Purity—Vanillin is easily dissolved by aqueous solutions of alkali hydroxides, and from these solutions, when not too dilute, it is precipitated at once by the addition of acids.

Vanillin melts between 80° and 82° C.

Its aqueous solution is acid to litmus paper and is optically inactive.

A saturated aqueous solution of Vanillin gives a blue color with ferric chloride T.S. On boiling the mixture, the blue color changes to brown, and on cooling, a white, or nearly white precipitate of dihydrodivanillin separates.

Vanillin is extracted completely from its solution in ether by shaking with a saturated, aqueous solution of sodium bisulphite, from which it is precipitated by the addition of sulphuric acid.

A cold aqueous solution of Vanillin gives with lead acetate T.S. a white precipitate of a lead compound of vanillin, which is soluble in hot water.

Ash: not more than 0.5 per cent.

Warm 0.1 Gm. of Vanillin with a concentrated alcoholic solution of sodium hydroxide, add a drop of chloroform, and again warm; the odor of phenylisocyanide is not perceptible (*acetanilid*).

Preserve in well-closed containers, protected from light.

N. F. Preparations—Elixir Amygdalæ Compositum; Elixir Vanillini Compositum (from Compound Spirit); Liquor Ferri Peptonati; Liquor Ferri Peptonati et Mangani; Oleum Ricini Aromaticum; Spiritus Vanillini Compositus; Tabellæ Santonini; Tabellæ Santonini Compositæ.

Uses—Vanillin is used as a flavoring agent. Dose of one-half to one grain (0.03 to 0.65 Gm.).

COUMARINUM. N. F. Coumarin

[Coumar.—Cumarin]

The anhydride of ortho-oxycinnamic acid [$C_6H_4(CH)_2OCO$ = 146.09], occurring naturally in tonka, melilot, and other plants, or prepared synthetically.

Official Description—In colorless, prismatic crystals.

Odor and Taste—Characteristic, fragrant odor and a bitter, aromatic and burning taste.

Solubility—Sparingly soluble in cold water, more readily soluble in hot water, freely soluble in alcohol, ether, or chloroform; also soluble in fixed or volatile oils.

Tests for Identity and Purity—When heated to between 67° and 68° C. it melts, and at about 100° C. commences to sublime; at from 290° to 291° C. it boils without decomposition.

Coumarin dissolves in solution of sodium or potassium hydroxide, producing a yellow color and forming sodium or potassium coumarate, from which carbon dioxide precipitates the Coumarin. Coumarin is precipitated in colorless needles on the addition of hydrochloric acid to its hot concentrated sodium or potassium hydroxide solution.

A saturated aqueous solution of Coumarin forms a precipitate upon the addition of iodine T.S. The precipitate is at first brown and flocculent and afterwards on shaking, clots together, forming a dark green curdy mass and leaving the liquid clear (distinction from *vanillin*).

Coumarin is not extracted from its solution in ether by ammonia water (distinction from *vanillin*).

Acetanilid—Warm 0.1 Gm. of Coumarin with 1 cc. of an alcoholic solution of sodium hydroxide (1 in 4), add a few drops of chloroform, and again warm; the mixture does not possess the disagreeable odor of phenylisocyanide.

N. F. Preparation—Oleum Ricini Aromaticum.

Uses—As a flavor, fixative, and perfume, having the odor known as *new-mown hay.*

OLEUM CAJUPUTI. U. S. Oil of Cajuput

[**Ol. Cajup.**—Cajuput Oil, Oil of Cajeput]

The volatile oil distilled from the fresh leaves and twigs of several varieties of *Melaleuca Leucadendron* Linné, especially the var. *Cajeputi* (Roxburgh) Niedenzu and the var. *minor* (Smith) Duthie (Fam. *Myrtaceæ*), rectified by steam distillation.

This aromatic oil has a penetrating odor, analogous to that of cardamom, and a warm, pungent taste. Its chief constituent has the formula $C_{10}H_{18}O$, and by repeated distillation over phosphoric oxide the hydrocarbon, $C_{10}H_{16}$, called *cajuputene*, can be obtained. The oil is, therefore, said to contain *cajuputene hydrate*, or *cajuputol*. The identity of cajuputol with *cineol* and *eucalyptol* from *Eucalyptus Globulus* in both chemical and physical properties has been established. It boils at 175° C. A second constituent of the formula, $C_{10}H_{18}O$, is the solid *terpineol*, which is present both in the free state and as acetic ester. A small amount of *l-pinene* and traces of aldehydes have been found, including *valeraldehyde* and *benzaldehyde*. When oil of cajuput is distilled, a light, colorless liquid first comes over, and afterwards a green and denser one. The green color has been ascribed to a salt of copper derived from the vessels in which the distillation is performed, and various investigators have found traces of copper present in it. Others, again, have carefully tested the green oil and proved its absence. A fair inference is that the oil of cajuput is naturally green, but as found in commerce it sometimes contains copper, either accidentally present, or added with a view of imitating or maintaining the fine color of the oil.

Description and Physical Properties—A colorless or yellowish liquid, having a peculiar, agreeable, distinctly camphoraceous odor, and an aromatic, slightly bitter taste.

Tests for Identity and Purity—The Oil is soluble in 1 volume of 80 per cent alcohol.

Specific gravity: 0.912 to 0.925 at 25° C.

Optical rotation: does not exceed −4° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4660 to 1.4710 at 20° C., page 1525.

Oil of Cajuput meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

Uses—Oil of cajuput is used chiefly as a local application in skin diseases. Sometimes it is employed in place of oil of eucalyptus as a stimulating expectorant, and is given in doses of eight minims (0.5 cc.).

EUCALYPTUS. U. S. Eucalyptus

[**Eucalypt.**—Blue Gum Leaves, Eucalyptus Leaves, Gum Wood, Blue Gum Tree, Fever Tree, Woody But.]

Eucalyptus is the dried, scythe-shaped leaf of *Eucalyptus Globulus* Labillardière (Fam. *Myrtaceæ*).

Eucalyptus contains not more than 3 per cent of stems, fruits, or other foreign organic matter.

Description—Petiolate, lanceolately scythe-shaped, from 15 to 30 cm. long, rounded below, tapering above, entire, leathery, grayish-green, glandular, feather-veined between the midrib and marginal veins; odor strongly camphoraceous; taste pungently aromatic and somewhat cooling, bitter, and astringent.

For further description see the U. S. P. X.

U. S. P. Preparation—Fluidextractum Eucalypti.

The virtues of eucalyptus leaves depend upon a volatile oil which should contain about 70 per cent of eucalyptol. There are also present resin, tannin, chlorophyl, fatty acid, etc.

Uses—The leaves are rarely used. Their virtues are the same as those of oil of eucalyptus. Dose, thirty grains (2 Gm.).

OLEUM EUCALYPTI. U. S. Oil of Eucalyptus

[**Ol. Eucalypt.**—Eucalyptus Oil]

The volatile oil distilled from the fresh leaves of *Eucalyptus Globulus* Labillardière, and from some other species of *Eucalyptus* (Fam. *Myrtaceæ*). Oil of Eucalyptus yields not less than 70 per cent of eucalyptol (cineol) [$C_{10}H_{18}O$].

The oil from *eucalyptus globulus* contains *pinene*, $C_{10}H_{16}$, and *eucalyptol* (or *cineol*), $C_{10}H_{18}O$, also several of the aldehydes of the fatty series, notably *valeraldehyde*, and probably *butyraldehyde* and *capronaldehyde*. The most valuable portion of the oil consists of *eucalyptol*, which is very soluble in alcohol. The proportion of eucalyptol is recognized as a useful test for the quality of the oil (see official assay below).

Description and Physical Properties—A colorless or pale yellow liquid, having a characteristic, aromatic, somewhat camphoraceous odor, and a pungent, spicy, cooling taste.

Tests for Identity and Purity—The Oil is soluble in 4 volumes of 70 per cent alcohol, by volume.

Specific gravity: 0.905 to 0.925 at 25° C.

Optical rotation: varies from −10° to +10° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4600 to 1.4690 at 20° C., page 1525.

A solution of the recently distilled Oil in 70 per cent alcohol (1 in 4) is neutral to moistened litmus paper.

Mix 2 cc. of Oil of Eucalyptus with 4 cc. of glacial acetic acid, and gradually add 3 cc. of a 20 per cent aqueous solution of sodium nitrite. When the mixture is gently stirred with a glass rod, crystals of phellandrene nitrite do not form (*eucalyptus oils containing large amounts of phellandrene*).

The Oil meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

Assay—The congealing point of Oil of Eucalyptus does not fall below −15.4° C., as determined by the method described on page 1524.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

Uses—Oil of eucalyptus is used as an expectorant in chronic bronchitis in doses of eight minims (0.5 cc.). Eucalyptol is preferred by some to oil of eucalyptus (see below).

EUCALYPTOL. U. S. Eucalyptol

[Cineol, Cajeputol]

A substance [$C_{10}H_{18}O = 154.19$] obtained from oil of eucalyptus and from other sources.

Preparation—Eucalyptol may be obtained from many volatile oils, and for that reason chemists prefer to call it *cineol*. It may be separated from the purified volatile oils by taking advantage of its property of forming crystals when subjected to a low temperature (−1° C.; 30.2° F.).

Description and Physical Properties—A colorless liquid, having a characteristic, aromatic, distinctly camphoraceous odor, and a pungent, spicy taste.

Eucalyptol is very slightly soluble in water. It is miscible with alcohol, chloroform, ether, glacial acetic acid, and with fixed or volatile oils.

Specific gravity: 0.921 to 0.923 at 25° C.

Tests for Identity—It boils between 174° and 177° C.

Congealing point: not below 0° C., page 1524.

Place 1 cc. of Eucalyptol in a freezing mixture, and gradually add an equal volume of phosphoric acid: a solid, white, crystalline mass of eucalyptol-phosphoric acid forms, and upon the addition of warm water, the Eucalyptol separates.

Tests for Purity—Its alcoholic solution (1 in 10) is neutral to moistened litmus paper.

Eucalyptol is optically inactive (*difference from oil of eucalyptus and many other volatile oils*).

Shake 5 cc. of Eucalyptol with 5 cc. of sodium hydroxide T.S.: the volume of the Eucalyptol is not diminished (*phenols, etc*).

Shake 1 cc. of Eucalyptol with 20 cc. of distilled water, and allow the liquids to separate. To 10 cc. of the aqueous layer, separated from the Eucalyptol, add 1 drop of ferric chloride T.S.: no violet color is produced (*phenols*).

U. S. P. Preparation—Fluidextractum Eucalypti.

N. F. Preparations—Liquor Antisepticus; Liquor Aromaticus Alkalinus; Liquor Pepsini Antisepticus; Nebula Aromatica; Nebula Eucalyptolis; Nebula Mentholis Composita; Petroxolinum Eucalyptolis; Petroxolinum Sulphuratum Compositum; Pulvis Antisepticus.

Uses—Eucalyptol is used internally as a stimulating expectorant. Locally it is employed for its antiseptic effect in inflammations of the nose and throat and in certain skin diseases. It is sometimes used also by inhalation in bronchitis. Dose, five minims (0.3 cc.).

Official Products from the Myristicaceæ

MYRISTICA. U. S. Myristica

[**Myrist.**—Nutmeg]

Myristica is the dried ripe seed of *Myristica fragrans* Houttuyn (Fam. *Myristicaceæ*), deprived of its seed coat and with or without a thin coating of lime.

Myristica yields not less than 25 per cent of non-volatile, ether-soluble extractive and not more than 0.5 per cent of acid-insoluble ash.

Description—Oval or roundish-ovate, about 25 mm. long, light brown, reticulately furrowed, with a circular scar on the broad end; internally pale brownish, with dark orange-brown veins, and of a fatty luster; odor strongly aromatic; taste aromatic, warm, and somewhat bitter. (For further description and tests see U. S. P. X.)

Assay—Proceed as directed under non-volatile ether-soluble extractive, page 1523.

For further description see the U. S. P. X.

U. S. P. Preparations—Tinctura Lavandulæ Composita; Tinctura Rhei Composita.

N. F. Preparations—Pulvis Aromaticus; Pulvis Cretæ Compositus; Syrupus Sennæ Aromaticus.

Uses—This valuable spice owes its activity to the presence of an oxygenated volatile oil. Nutmeg contains about 25 per cent of fixed oil, with proteins, starch, etc. It is used as a stimulating aromatic and as a flavor. Dose, eight grains (0.5 Gm.).

OLEUM MYRISTICÆ. U. S. Oil of Myristica

[**Ol. Myrist.**—Myristica Oil, Oil of Nutmeg]

The volatile oil distilled from the dried kernels of the ripe seed of *Myristica fragrans* Houttuyn (Fam. *Myristicaceæ*).

This oil consists chiefly of pinene, with probably some dipentene, also *myristicol*, $C_{10}H_{16}O$, and *myristicin*, $C_{11}H_{12}O$, linaloöl, borneol, terpineol, geraniol, eugenol, and a number of organic acids.

Expressed oil of nutmeg, or *oil of mace*, is made by expressing nutmegs between hot plates, or macerating them in carbon disulphide, and distilling the liquid to get rid of the solvent. It has been reported as containing the glyceride of myristic acid, $C_{14}H_{28}O_2$. It contains both fixed and volatile oil and is said to contain a toxic principle.

Description and Physical Properties—A colorless, or pale yellow liquid, having the characteristic odor and taste of nutmeg.

Tests for Identity and Purity—The Oil is soluble in an equal volume of alcohol and in 3 volumes of 90 per cent alcohol, by volume.

Specific gravity: 0.859 to 0.924 at 25° C.

Optical rotation: varies from +12° to +30° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4780 to 1.4895 at 20° C., page 1525.

A solution of the recently distilled Oil in an equal volume of alcohol is neutral or only slightly acid to moistened litmus paper.

Evaporate 3 Gm. of the Oil in a small tared dish on a bath of boiling water: the weight of the residue does not exceed 0.06 Gm.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparation—Spiritus Ammoniæ Aromaticus.

N. F. Preparations—Elixir Pepsini et Rennini Compositum; Mistura Oleo-Balsamica.

Uses—Oil of myristica is used in aromatic spirit of ammonia. In overdoses it acts as a narcotic poison. This oil is very difficult to keep and even if slightly terebinthinate is unfit for flavoring purposes. Dose, one-half minim (0.03 cc.).

Official Products from the Lauraceæ

SASSAFRAS. N. F. Sassafras

(U. S. P. IX)

[Sassaf.]

Sassafras is the dried bark of the root of *Sassafras variifolium* (Salisbury) O. Kuntze (Fam. *Lauraceæ*).

Sassafras contains not more than 4 per cent of adhering wood, outer corky tissues, or foreign organic matter and yields not more than 5 per cent of acid-insoluble ash.

Description—In irregular fragments, deprived of the gray, corky layer; bright rust-brown, soft, fragile, with a short, corky fracture; the inner surface smooth; strongly fragrant; taste sweetish, aromatic, and somewhat astringent.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Sarsaparillæ Compositum; Decoctum Sarsaparillæ Compositum; Syrupus Pini Albæ Compositus; Syrupus Pini Albæ Compositus cum Morphina.

This well known bark contains volatile oil (mainly safrol), sassafrid, tannin, starch, resin, etc.

Uses—It is principally used on account of its aromatic oil, largely in domestic practice, and as an addition to proprietary medicines for the purpose of covering the taste of disagreeable substances. Dose, two and one-half drachms (10 Gm.).

OLEUM SASSAFRAS. U. S. Oil of Sassafras

[Ol. Sassaf.—Sassafras Oil]

The volatile oil distilled from the root of *Sassafras variifolium* (Salisbury) O. Kuntze (Fam. *Lauraceæ*). If the Oil has solidified in whole or in part, carefully warm it until liquefied, then thoroughly mix it before dispensing.

This oil was formerly largely produced in New Jersey and Maryland from the wood and bark of the sassafras tree; the yield is about 2 per cent. It consists of a terpene, $C_{10}H_{16}$ (*safrene*), and an oxygenated portion, $C_{10}H_{10}O_2$, *safrol*, is the methylene ether of allyl pyrocatechol and is made on a large scale by chilling the oils of camphor and other safrol-containing oils; the crystals are separated, and allowed to melt, forming liquid safrol. It has also been made synthetically. It is a colorless or faintly yellow liquid with a sassafras-like odor. Specific gravity, 1.098 to 1.100 at 25° C. It is soluble in about an equal volume of strong alcohol, and in about 30 parts of 70 per cent alcohol. Miscible in all proportions with ether and chloroform. Boiling point: about 233° C.; optically inactive. On cooling to −20° C. or below, it solidifies to a mass of crystals,

which do not melt below 11° C. It is used for scenting soaps and as a substitute for oil of sassafras.

The oil is officially described as follows:

Description and Physical Properties—A yellow or reddish-yellow liquid, having the characteristic odor and taste of sassafras.

Tests for Identity and Purity—The Oil is soluble in 2 volumes of 90 per cent alcohol, by volume.

Specific gravity: 1.065 to 1.077 at 25° C.

Optical rotation: varies from +3° to +4° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.5250 to 1.5350 at 20° C., page 1525.

A solution of the recently distilled Oil in 90 per cent alcohol (1 in 2) is neutral to moistened litmus paper.

Oil of Sassafras meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

U. S. P. Preparation—Syrupus Sarsaparillæ Compositus.

N. F. Preparations—Syrupus Eriodictyi Aromaticus; Syrupus Pini Albæ Compositus; Syrupus Pini Albæ Compositus cum Morphina; Syrupus Trifolii Compositus.

Uses—Oil of sassafras is largely used as a flavoring agent by confectioners. It is a powerful antiseptic and is sometimes used as a local application in nose and throat diseases. The official preparations are given above. It may be given in the dose of one and one-half minims (0.1 cc.).

Official Products from the Betulaceæ

METHYLIS SALICYLAS. U. S. Methyl Salicylate

[**Methyl. Salicyl.**—Oil of Gaultheria, Oil of Wintergreen, Oil of Betula, Oil of Sweet Birch, Oil of Teaberry, Artificial Oil of Wintergreen, Synthetic Oil of Wintergreen]

Methyl Salicylate is produced synthetically or is obtained by distillation from the leaves of *Gaultheria procumbens* Linné (Fam. *Ericaceæ*) or from the bark of *Betula lenta* Linné (Fam. *Betulaceæ*). The label must indicate whether the Methyl Salicylate has been made synthetically or distilled from either of the above mentioned plants. It contains not less than 98 per cent of $C_6H_4(OH)CO_2CH_3$(152.10).

Preparation—In the U. S. P., oil of gaultheria, oil of betula, and methyl salicylate are combined under the latter title, as it is difficult to distinguish between them chemically, and practically the same tests apply to all. The most important differences in the tests are found in the specific gravity and optical rotation but these factors are not sufficiently characteristic to enable the detection of either in a mixture. The U. S. P. directs that the label shall indicate the source of the product and whether synthetic or natural. Methyl Salicylate is found naturally in the oils of gaultheria and betula and in many other plants, but the commercial product is usually made by distilling salicylic acid or a salicylate with methyl alcohol and strong sulphuric acid.

Description and Physical Properties—A colorless, yellowish, or reddish liquid, having the characteristic odor and taste of gaultheria.

Methyl Salicylate is slightly soluble in water, but is miscible with alcohol and with glacial acetic acid. It is soluble in about 7 volumes of 70 per cent alcohol at 25° C. with not more than a slight cloudiness.

Tests for Identity—Specific gravity at 25° C.: synthetic, 1.180 to 1.185; from gaultheria or betula, 1.176 to 1.182.

It boils between 219° and 224° C.

Synthetic Methyl Salicylate, or that from betula, is optically inactive. Methyl Salicylate from gaultheria is slightly levorotatory, not exceeding −1.5° in a 100 mm. tube at 25° C.

A deep violet color is produced by shaking a drop of Methyl Salicylate with about 5 cc. of distilled water and adding a drop of ferric chloride T.S.

Tests for Purity—An alcoholic solution of Methyl Salicylate is neutral or slightly acid to moistened litmus paper.

Add 10 cc. of potassium hydroxide T.S. to 1 cc. of Methyl Salicylate contained in a capacious test tube, and agitate the mixture: a clear, or slightly cloudy, and colorless or faintly yellowish solution results without the separation of any oily drops either on the surface or at the bottom of the liquid (*other volatile oils or petroleum products*).

Methyl Salicylate meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

Assay—Place about 2 cc. of Methyl Salicylate, accurately weighed, in a tared flask, add 50 cc. of half-normal alcoholic potassium hydroxide, connect the flask with a reflux condenser, and heat the mixture on a water bath for two hours. Add a few drops of phenolphthalein T.S., and titrate the excess of alkali with half-normal hydrochloric acid. Each cc. of half-normal alcoholic potassium hydroxide corresponds to 0.07605 Gm. of $C_6H_4(OH)CO_2CH_3$.

This assay is explained on page 1461.

Preserve in well-stoppered, amber-colored bottles, in a cool place.

U. S. P. Preparations—Emulsum Olei Morrhuæ; Fluidextractum Cascaræ Sagradæ Aromaticum; Syrupus Sarsaparillæ Compositus.

N. F. Preparations—Cataplasma Kaolini; Dentifricium; Inunctum Mentholis Compositum; Liquor Antisepticus; Liquor Aromaticus Alkalinus; Liquor Ferri Salicylatis; Liquor Pepsini Antisepticus; Nebula Aromatica; Nebula Mentholis Composita; Odontalgicum; Petroxolinum Methylis Salicylatis; Syrupus Trifolii Compositus; Trochisci Ulmi.

Uses—Methyl salicylate is used in place of salicylic acid in rheumatism, neuralgia, and kindred diseases. The synthetic product has largely replaced the natural oils, and by many is believed to be identical in its medical properties. As a flavoring agent it is equal in every respect to oil of wintergreen or oil of sweet birch. Care must be taken to select a product conforming to the official tests. Dose, twelve minims (0.75 cc.).

Official Products from the Zingiberaceæ

CARDAMOMI SEMEN. U. S. Cardamom Seed

[**Cardam. Sem.**—Cardamom, Ceylon or Malabar Cardamom]

Cardamom Seed is the dried ripe seed of *Elettaria Cardamomum* Maton (Fam. *Zingiberaceæ*), recently removed from the capsules.

Cardamom Seed yields not more than 5 per cent of acid-insoluble ash.

Description—The seeds are about 4 mm. long, reddish-brown, angular, rugose, depressed at the hilum, surrounded by a thin, membranous arillus, and have an agreeable odor and a pungent aromatic taste.

For further description see the U. S. P. X.

U. S. P. Preparations—Extractum Colocynthidis Compositum; Tinctura Cardamomi; Tinctura Cardamomi Composita; Tinctura Gentianæ Composita; Tinctura Rhei.

N. F. Preparations—Pulvis Aromaticus; Pulvis Cretæ Aromaticus; Elixir Gentianæ Glycerinatum (from Compound Tincture); Syrupus Eriodictyi Aromaticus (from Compound Tincture); Tinctura Aromatica; Tinctura Rhei Dulcis.

This valuable aromatic is imported from India. The seeds contain 5 per cent of an oxygenated volatile oil, of the sp. gr. 0.943, 10 per cent of fixed oil, starch, mucilage, etc. Owing to the presence of the fixed oil, the seeds are very difficult to powder alone, hence the practice in preparing compound powders containing cardamom of mixing the other ingredients with it, so that they may absorb the oil. An oil of cardamom which is a mixture of both volatile and fixed oils, is sometimes made by percolation with ether. This must not be confused with the official volatile oil.

Uses—It is a flavor, aromatic, stomachic, and carminative. Dose, fifteen grains (1 Gm.).

OLEUM CARDAMOMI. N. F. Oil of Cardamom

[**Ol. Cardam.**]

A volatile oil distilled from the seeds of *Elettaria Cardamomum* White et Maton (Fam. *Zingiberaceæ*).

Official Description—A colorless or very pale yellow liquid.

Odor and Taste—Characteristic, aromatic, penetrating and somewhat camphoraceous odor of cardamom, and a persistent, pungent, and strongly aromatic taste.

Solubility—Soluble in alcohol and readily soluble in four volumes of 70 per cent alcohol, forming a clear solution.

Specific gravity: 0.924 to 0.947 at 25° C.

Tests for Identity and Purity—It is dextrorotatory, the angle of rotation varying from +22° to +44°, in a 100 mm. tube, at 25° C.

Preserve it in small, well-stoppered, amber-colored bottles, in a cool place, protected from light.

N. F. **Preparations**—Elixir Cardamomi Compositum (from Compound Spirit); Elixir Vanillini Compositum (from Compound Spirit); Spiritus Cardamomi Compositus; Spiritus Vanillini Compositus.

Uses—It is used as a flavor and as a stomachic.

ZINGIBER. U. S. Ginger

[**Zingib.**—Jamaica Ginger, African Ginger, Cochin Ginger, Ginger Root, Black Ginger]

Ginger is the dried rhizome of *Zingiber officinale* Roscoe (Fam. *Zingiberaceæ*), known in commerce as Jamaica Ginger, Cochin Ginger, and African Ginger. The outer cortical layers are often either partially or completely removed.

Ginger yields not less than 2 per cent of non-volatile, ether-soluble extractive and not less than 12 per cent of cold water-extractive.

Descriptions—

Jamaica Ginger—Rhizome horizontal, laterally compressed, irregularly branched, from 4 to 16 cm. in length and from 4 to 20 mm. in thickness; the cork wholly removed; externally light brown, longitudinally striate, ends of the branches with depressed stem-scars; fracture short, fibrous, starchy and resinous; internally yellowish to light brown; odor agreeably aromatic; taste aromatic and pungent.

Cochin Ginger—Cork almost or wholly removed on the flattened sides, light brown to grayish-yellow, fracture shorter, less fibrous and more starchy than other varieties; internally yellowish-white; oil and resin cells vary from yellowish to brownish-red; odor aromatic, taste pungent.

African Ginger—Cork partly removed on the flattened sides, leaving light brownish areas; portions with cork, longitudinally or reticulately wrinkled and grayish-brown; internally light yellow to brown; taste aromatic and strongly pungent; otherwise resembling Jamaica Ginger.

Assay—Place 4 Gm. of ground Ginger in a 200 cc. flask, fill to the mark with distilled water, and agitate at half-hour intervals during eight hours. Then allow the mixture to stand for sixteen hours and filter. Evaporate 50 cc. of the filtrate, representing 1 Gm. of the drug, on a water bath, dry to constant weight at 100° C., and weigh. It yields not less than 12 per cent of cold water-extractive.

For non-volatile, ether-soluble extractive, proceed as directed on page 1523.

For further description see the U. S. P. X.

U. S. P. **Preparations**—Fluidextractum Zingiberis; Pulvis Rhei Compositus; Syrupus Zingiberis (from Fluidextract); Tinctura Zingiberis.

N. F. **Preparations**—Pulvis Aromaticus; Pulvis Aromaticus Rubefaciens; Pulvis Myricæ Compositus; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe; Tinctura Aromatica.

Uses—This well-known and largely used rhizome owes its virtues to about 4 per cent of volatile oil, having the composition $C_{10}H_{16}$, and therefore a terpene, and a soft, pungent, aromatic resin, which is soluble in alcohol and ether. Ginger is used as an intestinal stimulant and carminative in colic and diarrhea in doses of eight grains (0.5 Gm.).

ZEDOARIA. N. F. Zedoary

[**Zedoar.**]

Zedoary is the dried rhizome of *Curcuma Zedoaria* (Bergius) Roscoe (Fam. *Zingiberaceæ*).

Zedoary contains not more than 2 per cent of foreign organic matter.

Description—The rhizome, or, more properly, tuber, is terete and somewhat thicker than curcuma, and, to facilitate drying is sliced, mostly transversely. It occurs in nearly circular (occasionally oval) disks, from 1 to 4 cm. broad, and 4 to 10 mm. thick, the thickness almost uniform at margin and center. The edges are grayish-brown and wrinkled, the cut surfaces white or grayish-white and smooth, with a dark endodermal circle near the margin.

For further description see the N. F. V.

N. F. **Preparations**—Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Tinctura Amara; Tinctura Antiperiodicæ; Tinctura Antiperiodicæ sine Aloe.

Uses—It is a stimulating aromatic in colic and digestive debility. The dose is fifteen grains (1 Gm.).

Official Product from the Aristolochiaceæ

ASARUM. N. F. Asarum

[Asar.—Canada Snakeroot, Wild Ginger]

Asarum consists of the dried rhizome and roots of *Asarum canadense* Linné (Fam. *Aristolochiaceæ*).

Asarum contains not more than 5 per cent of foreign organic matter. Its chief constituent is a volatile oil largely used in perfumery.

Description—From 7 to 15 cm. long and about 3 mm. thick, somewhat bent and curved, with few branches and few thin, nearly simple roots, which are 5 to 7 cm. long; nodes often presenting a pointed appearance from the remains of the petioles; externally deep purple-brown, internally whitish; the bark occupying about $\frac{1}{6}$ of the diameter and containing the oil cells, the wood in about twelve small wedge-shaped bundles, forming an interrupted circle and enclosing a large pith; odor aromatic, taste pungent and bitter.

For further description see the N. F. V.

N. F. Preparation—Syrupus Asari Compositus.

Uses—A feeble aromatic, dose thirty grains (2 Gm.).

Unofficial Terpenes

Oil of Burgundy Pitch	From *Abies excelsa*. Fam. Coniferæ. Habitat, Europe
Calamus	From the rhizome of *Acorus calamus*. Fam. Araceæ. Habitat, North America
Canada Turpentine	From the oleoresin of *Abies balsamea*. Fam. Coniferæ
Cedrat	From *Citrus medica*. Fam. Rutaceæ. Used in perfumery
Elemi	From *Canarium commune*. Fam. Burseraccæ. Habitat, Philippine Islands
Gurjun Balsam	From *Dipterocarpus turbinatus*. Fam. Dipterocarpaceæ. Habitat, India
Hemlock Spruce	From *Abies canadensis*. Fam. Pinaceæ. Habitat, Canada
Hungarian Turpentine	From *Pinus pumilio*. Fam. Pinaceæ
Jaborandi	From the leaflets of *Pilocarpus pinnatifolius*. Fam. Rutaceæ. Habitat, Brazil
Oil of Myrtle	From *Myrtus communis*. Fam. Myrtaceæ
Sage	From the leaves of *Salvia officinalis*. Fam. Labiatæ
Strassburg Turpentine	From *Abies pectinata*. Fam. Pinaceæ
Templin	From the shoots of *Pinus pumilio*. It is a colorless or yellowish-green oil, of an agreeable, somewhat terebinthinate odor

Unofficial Oxygenated Oils

Oil of Absinthium	From *Artemisia absinthium*. Fam. Compositæ
Angustura	From the bark of *Galipea cusparia*. Fam. Rutaceæ. Habitat, South America. Composition, $C_{13}H_{24}O$
Anthemis	From the flower heads of *Anthemis nobilis*. Fam. Compositæ. Habitat, Europe
Arnica	From the root and flowers of *Arnica montana*. Fam. Compositæ. Habitat, Europe
Asarum	From the rhizome of *Asarum canadense*. It is used to give permanence to the odors of some cologne waters
Buchu	From the leaves of *Barosma betulina, B. crenulata, and B. serratifolia*. Fam. Rutaceæ. Habitat, Southern Africa
Camphor	From the preparation of crude camphor. Fam. Laurineæ. Habitat, Asia
Canella	From the bark of *Canella alba*. Fam. Canellaceæ. Habitat, Southern United States
Capsicum	From the fruit of *Capsicum fastigiatum*. Fam. Solanaceæ. Habitat, Southern and Central America
Carrot	From the fruit of *Daucus carota*. Fam. Umbelliferæ. Indigenous to Northern Asia
Cascarilla	From the bark of *Croton eluteria*. Fam. Euphorbiaceæ. Indigenous to the Bahama Islands
Catnep	From the leaves and tops of *Nepeta cataria*. Fam. Labiatæ. Habitat, Europe
Celery	From the fruit of *Apium graveolens*. Fam. Umbelliferæ. Habitat, Europe
Citronella	From the leaves of *Andropogon nardus*. Habitat, Ceylon. Contains a terpene, citronellol, and a heptoic aldehyde. Used in perfumery
Curcuma	From the rhizome of *Curcuma longa*. Fam. Zingiberaceæ. Habitat, India
Cyna	From the flowers of *Artemisia maritima*. Fam. Compositæ. Habitat, Asia. A pale yellow oil
Dahlia	From the tubers of *Dahlia pinnata*
Elder (European)	From the flowers of *Sambucus nigra*. Fam. Caprifoliaceæ. Habitat, Europe
Feverfew	From *Pyrethrum parthenium*. Fam. Compositæ. Habitat, Europe
Galangal	From the rhizome of *Alpinia officinarum*. Fam. Zingiberaceæ. Habitat, China
Ginger	From the rhizome of *Zingiber officinale*. Fam. Zingiberaceæ. Habitat, Jamaica
Ginger Grass	From the flowers of *Andropogon Schœnanthus*
Golden Rod	From the leaves of *Solidago odora*
Hedeoma	A volatile oil distilled from the leaves and flowering tops of Hedeoma, the dried
Oil of Pennyroyal	leaves and flowering tops of *Hedeoma pulegioides* (Linné) Persoon (Fam. *Labiatæ*). A pale yellow limpid liquid of characteristic, pungent, mint-like odor and taste. Sp. gr. 0.920 to 0.935 at 25° C. It forms a clear solution with 2 volumes or more of 70 per cent alcohol. Dextrogyrate, the angle of rotation varying from about +18° to +22° in a 100 mm. tube, at a temperature of 25° C. (77° F.). This is an oxygenated oil, and is used principally to protect the exposed parts of the body from the bites of flies, mosquitoes, fleas, etc. It is employed sometimes in amenorrhea, in doses of one to three minims (0.06 to 0.2 cc.). The drug was official in the U. S. P. VIII. It is a stimulant and aromatic. Dose, two drachms (8 Gm.).
Oil of Heliotrope	From the flowers of *Heliotropium peruvianum* and *H. grandiflorum*
Hop	From the strobiles of *Humulus lupulus*. Fam. Urticaceæ. Habitat, North America

Unofficial Oxygenated Oils—*Continued*

Horsemint	From the leaves and flowers of *Monarda punctata*. Fam. Labiatæ. Habitat, United States
Hyssop	From the herb of *Hyssopus officinalis*. Fam. Labiatæ. Habitat, Southern Europe
Indian Cannabis	From *Cannabis sativa*. Fam. Moraceæ. Habitat, Asia
Inula	From the root of *Inula helenium*. Fam. Compositæ. Habitat, Europe
Jessamine	From the flowers of *Jasminium grandiflorum* and *J. fragrans*. Fam. Jasmineæ. Used in perfumery
Laurel	From *Laurus nobilis*. Fam. Lauraceæ. Habitat, Southern Europe
Lilac	From the flowers of *Syringa vulgaris*. Fam. Oleaceæ. Used in perfumery
Lily of the Valley	From the flowers of *Convallaria majalis*. Fam. Liliaceæ. Used in perfumery
Oil of Linden	From the inflorescence of different species of *Tilia*. Fam. Tiliaceæ. Habitat, Europe and America.
Lovage	From the root of *Levisticum officinale*. Fam. Umbelliferæ. Habitat, Europe
Marrubium	From *Marrubium vulgare*. Fam. Labiatæ. Habitat, Europe and Asia
Marsh Tea	From the leaves of *Ledum palustre*. Fam. Ericaceæ. Habitat, Europe and Asia
Masterwort	From *Heracleum lanatum*. Fam. Umbelliferæ. Habitat, United States
Matico	From the leaves of *Piper angustifolium*. Fam. Piperaceæ. Habitat, tropical America
Matricaria	From the flowers of *Matricaria chamomilla*. Fam. Compositæ. Habitat, Europe and United States
Melissa	From the leaves and tops of *Melissa officinalis*. Fam. Labiatæ. Habitat, Europe and United States
Mignonette	From the flowers of *Reseda odorata*. Fam. Resecaceæ. Habitat, Southern France. The yield is very small. Used in perfumery
Mountain Balm	From the leaves of *Eriodictyon californicum*. Fam. Hydrophyllaceæ. Habitat, California
Myrrh	From the gum-resin of *Commiphora myrrh*. Fam. Burseraceæ. Habitat, Arabia
Olibanum	From *Boswellia Carterii*. Fam. Burseraceæ. Habitat, Arabia.
Parsley	From the fruit of *Petroselinum sativum*. Fam. Umbelliferæ. Habitat, Southern Europe
Patchouly	From *Pogostemon Patchouly*. Fam. Labiatæ. Habitat, East India
Phellandrium	From the fruit of *Œnanthe phellandrium*. Fam. Umbelliferæ
Red Cedar	From *Juniperus virginiana*. Fam. Pinaceæ. Habitat, Canada and United States
Rhodium	From the root of *Convolvulus Scoparius*. Habitat, Canary Islands. The oil *of rhodium* sold in pharmacy is usually a factitious article, made by mixing 1 part of oil of rose with 20 parts of oil of copaiba. It is used as a lure for rats
Saffron	From *Crocus sativus*. Fam. Irideæ. Habitat, Europe
Serpentaria	From the rhizome and roots of *Aristolochia Serpentaria* and *A. reticulata*. Fam. Aristolochiaceæ. Habitat, Virginia
Summer Savory	From the herb of *Satureja hortensis*. Fam. Labiatæ
Sweet Basil	From *Ocymum basilicum*. Fam. Labiatæ. Habitat, Asia and Africa
Sweet Cicely	From *Osmorhiza longistylis*. Fam. Umbelliferæ
Sweet Marjoram	From *Origanum marjorana*. Fam. Labiatæ
Sweet Violet	From the flowers of *Viola odorata*. Fam. Violaceæ
Tansy	From the leaves of *Tanacetum vulgare*. Fam. Compositæ. Habitat, Europe and North America
Tea	From the leaves of *Thea sinensis*. Fam. Ternstræmiaceæ. Habitat, China
Thuja	From the branches of *Thuja occidentalis*. Fam. Coniferæ. Habitat, Canada and United States
Tuberose	From the flowers of *Polianthes tuberosa*. Fam. Amaryllidaceæ
Verbena (Lemongrass)	From *Andropogon citratis*. A grass cultivated in Ceylon and Singapore
Wormwood	From the herb of *Artemisia absinthium*. Fam. Compositæ. Habitat, Europe
Ylang-Ylang	An annonaceous tree (*Canangium odoratum*) of Malaysia, the Philippines, etc. It has greenish-yellow, very fragrant flowers, and is often planted for shade. Also the name for an essence or perfume distilled from the flowers of this tree (see Part VI).
Zedoary	From the rhizome of *Curcuma Zedoaria*. Fam. Zingiberaceæ. Habitat, East India Islands

Stearoptenes from Volatile Oils

CAMPHORA. U.S. Camphor

[**Camph.**—Gum Camphor, Powdered Camphor]

A dextrorotatory ketone [$C_9H_{16}CO$], obtained from *Cinnamomum Camphora* (Linné) Nees et Ebermaier (Fam. *Lauraceæ*).

Preparation—Refined camphor is usually made by subliming in circular cakes the crude granular camphor imported from China and Japan. The vessels in which the camphor is sublimed are of cast iron, circular, from twelve to fifteen inches or more in diameter, and four inches deep, with perpendicular sides, and a ledge at the top, on which the cover rests. This consists of sheet iron, with a hole through the center about an inch in diameter, over which a small hollow cone of sheet iron is placed loosely. The crude camphor, mixed with lime—the object of which is to combine with the moisture present

which would interfere with the subsequent solidification of the camphor vapor—is placed in the iron vessels described, of which from twenty to fifty are arranged in a long sand bath. Heat is then applied until the camphor melts, after which the heat is kept as nearly uniform as possible, so that the vaporization may take place regularly, without violent ebullition. The camphor sublimes on the lower surface of the lid in a solid circular cake, care being taken, by the occasional removal of the iron cone and clearing of the opening by means of a knife, to allow the escape of any excess of the vapor; the round hole in the cakes is thus accounted for. Camphor is sometimes sublimed in powder by conducting the vapor into a large cold chamber (see Sublimation, page 146). This powder is often compressed into oblong cakes, forming *compressed camphor*. Japanese camphor, refined in Formosa, and put up in ounce cakes and pound packages is now supplied. Camphor is now made synthetically by the interaction of oil of turpentine and anhydrous oxalic acid, the resulting mixture being treated with lime, and then distilled. This product is optically inactive and, not being chemically identical with the natural article, is not recognized by the U. S. P.

When camphor is triturated in nearly molecular proportions, with menthol, thymol, phenol or hydrated chloral, liquefaction ensues, the solution being known as a *eutectic solution.*

Description and Physical Properties—White, translucent, tough masses or granules. It has a penetrating, characteristic odor, and a pungent aromatic taste. It is readily pulverizable in the presence of a little alcohol, ether, or chloroform. It slowly volatilizes at ordinary temperatures.

One Gm. of Camphor is soluble in about 800 cc. of water, 1 cc. of alcohol, 0.5 cc. of chloroform, and in 1 cc. of ether, at 25° C. It is freely soluble in carbon disulphide, petroleum benzin, and in fixed or volatile oils.

Tests for Identity—Specific gravity: about 0.990 at 25° C.

Camphor melts between 174° and 177° C.

The specific rotation $[\alpha]_D$ of Camphor, determined at 25° C. in a solution containing 10 Gm. of Camphor in 100 cc. of alcohol and using a 200 mm. tube, is between +41° and +42°.

Tests for Purity—A solution of Camphor in petroleum benzin (1 in 10) is clear (*water*).

Gradually heat about 2 Gm. of Camphor: it sublimes without carbonization and without leaving more than 0.05 per cent of non-volatile matter.

Wind the end of a copper wire into a spiral about 6 mm. in diameter and 6 mm. in length, and hold it in a non-luminous flame until it glows without coloring the flame green. Dip the spiral in the Camphor, ignite, allow it to burn outside of the flame, and then bring the spiral into contact with the lower, outer edge of a non-luminous flame: not even a transient green color is imparted to the flame (*chlorinated products*).

Preserve in well-closed containers, in a cool place.

U. S. P. Preparations—Aqua Camphoræ; Collodium Flexile; Linimentum Camphoræ; Linimentum Chloroformi (from Soap Liniment); Linimentum Saponis; Spiritus Camphoræ; Tinctura Opii Camphorata.

N. F. Preparations—Ampullæ Camphoræ; Ceratum Camphoræ (from Liniment); Ceratum Plumbi Subacetatis; Chloral Camphoratum; Emplastrum Fuscum Camphoratum; Linimentum Belladonnæ; Linimentum Opii Compositum; Linimentum Saponato-Camphoratum; Linimentum Sinapis Compositum; Lotio Ammoniacalis Camphorata (from Spirit of Camphor); Menthol Camphoratum; Mistura Opii et Chloroformi Composita (from Spirit); Mistura Opii et Rhei Composita (from Spirit); Nebula Aromatica; Nebula Mentholis Composita; Petroxolinum Chloroformi Camphoratum; Petroxolinum Phenolis Camphoratum; Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Pilulæ Opii et Camphoræ; Tinctura Antiperiodicæ; Tinctura Antiperiodicæ sine Aloe; Unguentum Camphoræ.

Uses—Camphor is used internally in hysteria and neuralgic headaches. Hypodermically it is a valuable heart stimulant. Locally it is employed in nose and throat diseases as a counterirritant in liniments. Doses of two to ten grains (0.125 to 0.6 Gm.) by the mouth, and in one-half to two grains (0.03 to 0.125 Gm.) hypodermically. When it is required as a diffusible stimulant in threatened collapse, it is injected hypodermically and a sterile 10 per cent solution in olive oil is used. There are numerous official preparations, the list being given above.

CAMPHORA MONOBROMATA. U. S. P. IX. Monobromated Camphor

Ortho-monobromcamphor [$C_{10}H_{15}C_9H_{15}Br.CO$ = 231.09].

Preparation—This compound of camphor may be made by adding 4 ounces of bromine gradually to a retort in which thirteen ounces of camphor have been previously placed. In fifteen or twenty minutes a brisk reaction will commence. When this subsides, eight or nine ounces more of bromine are to be poured in, in four portions, waiting after each addition until the reaction ceases. The liquid in the retort is now heated to about 132° C., then cooled and sufficient petroleum benzin added to dissolve the crystalline mass. The crystals which are formed on cooling may be purified by recrystallization from petroleum benzin or hot alcohol.

Description—In colorless, prismatic needles or scales, or as a powder.

Odor and Taste—It has a mild but characteristic, camphoraceous odor and taste. Permanent in the air. It is decomposed by prolonged exposure to the sunlight.

Solubility—One Gm. of Monobromated Camphor dissolves in 6.5 cc. of alcohol, 0.5 cc. of chloroform, and in 1.6 cc. of ether at 25° C. (77° F.); almost insoluble in water.

Tests for Identity and Purity—It melts between 74° and 76° C.

Heat a mixture of about 0.1 Gm. each of Monobromated Camphor and silver nitrate and 2 cc. each of nitric acid and sulphuric acid until nitrous vapors are no longer evolved: a yellowish precipitate of silver bromide is obtained.

Incinerate about 2 Gm. of Monobromated Camphor: not more than 0.05 per cent of ash remains.

Soluble Bromide—Shake about 0.5 Gm. of powdered Monobromated Camphor with 10 cc. of distilled water and filter. The filtrate is neutral to litmus and is not rendered more than slightly opalescent by the addition of a few drops of silver nitrate T.S.

Preserve it in well-closed containers, protected from light.

Uses—Monobromated camphor is given as a nerve sedative, especially in neuralgic headaches in doses of two to five grains (0.125 to 0.3 Gm.).

Unofficial Preparations of Camphor

Cream of Camphor

Castile Soap, dry and grated	120 gr.
Ammonium Carbonate (translucent)	120 gr.
Powdered Camphor	120 gr.
Oil of Thyme	1 fl. dr
Oil of Turpentine	2 fl. oz.
Tincture of Opium	2 fl. oz.
Water, a sufficient quantity	
To make	1 pint

Dissolve the soap and the ammonium carbonate in 10 fl. oz. of hot water and pour in a pint bottle. Dissolve the camphor in the mixed oils, add to the soap solution, shaking the mixture. Add the tincture of opium and sufficient water to make 1 pint.

Camphoric Acid, $C_8H_{14}(COOH)_2$, which was official in the U. S. P. VIII, is an oxidation product of camphor, obtained by treating camphor with hot nitric acid. It is used in the treatment of bronchitis and phthisis in doses of fifteen grains (1 Gm.).

Official Substances Containing Nitrogenated or Sulphurated Oils with Allied Products

OLEUM AMYGDALÆ AMARÆ. U. S. Oil of Bitter Almond

[Ol. Amygd. Amar.—Bitter Almond Oil]

The volatile oil is obtained by maceration with water and subsequent distillation with steam from the dried ripe kernels (deprived of fixed oil) of *Amygdalus communis* Linné (Fam. *Rosaceæ*), or from other kernels containing amygdalin. The botanical source from which the Oil is derived must be stated on the label.

Oil of Bitter Almond yields not less than 85 per cent of benzaldehyde [C_7H_6O] and not less than 2 per cent and not more than 4 per cent of hydrocyanic acid (HCN). Oil in which crystals have formed must not be dispensed.

Note—This Oil is intended for medicinal use and neither it nor its solution should be used or sold for flavoring foods. The oil from which the hydrocyanic acid has been removed is used for this purpose.

Preparation—Oil of bitter almond is produced as the result of the reaction of emulsin on amygdalin in aqueous mixture of ground almond; it therefore does not preëxist in the almond and cannot be obtained from sweet almond, because amygdalin is not present in the latter. It is now permitted to be made from other kernels containing amygdalin, such as peach and apricot kernels, but the source must be stated upon the label.

$$\underset{\text{amygdalin}}{C_{20}H_{27}NO_{11}} + \underset{\text{water}}{2H_2O} = \underset{\text{benzaldehyde}}{C_7H_6O} + \underset{\text{dextrose}}{2C_6H_{12}O_6} + \underset{\text{hydrocyanic acid}}{HCN}$$

The process consists in taking a mixture of the bitter almond press cake (obtained after the fixed oil has been extracted) with water, and distilling it by passing a current of steam through it. The proportions of benzaldehyde and hydrocyanic acid in the oil are recognized as valuable tests (see official assay below, also Benzaldehydum, page 990).

Description and Physical Properties—A clear, colorless or yellow, strongly refractive liquid, having the characteristic odor and taste of benzaldehyde.

When first prepared, the Oil is neutral to moistened litmus paper, but afterward develops an acid reaction, due to the formation of benzoic acid.

Tests for Identity and Purity—The Oil is slightly soluble in water and is soluble in all proportions in alcohol and in ether. It forms a clear solution with 2 volumes of 70 per cent alcohol, by volume.

Specific gravity: 1.038 to 1.060 at 25° C.

Optical rotation: varies from inactive to +0° 10′ in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.5428 to 1.5439 at 20° C., page 1525.

The Oil meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

Rinse the interior surface of a well-cleaned, 1000 cc. beaker, with distilled water, and pass the washings through a small filter until the addition of 1 drop of silver nitrate T.S. to a portion of the filtrate, acidulated with 1 drop of nitric acid, shows no turbidity. Place 3 or 4 drops of the Oil on a clean watch glass supported on a triangle, ignite, and immediately cover with the moistened beaker. Wash the products of combustion from the sides of the beaker through the washed filter with 10 to 20 cc. of distilled water, and acidulate the filtrate with 1 drop of nitric acid: the addition of 1 drop of silver nitrate T.S. produces no turbidity (*chlorinated products*).

Add 10 drops of Oil of Bitter Almond to 5 cc. of alcohol, then add a small amount of zinc dust and 2 cc. of acetic acid, and boil the mixture for about ten seconds: no odor of phenylisocyanide develops after rendering the liquid strongly alkaline with sodium hydroxide T.S. and then adding a few drops of chloroform and heating (*nitrobenzene*).

Assay for Benzaldehyde—Dissolve about 3 cc. of freshly redistilled phenylhydrazine in about 60 cc. of alcohol, and titrate 25 cc. of this solution, which must be freshly prepared, with half-normal hydrochloric acid, using 1 drop of methyl orange T.S. as indicator. To about 1 Gm. of Oil of Bitter Almond, accurately weighed, add another 25 cc. portion of the phenylhydrazine solution, and allow the mixture to stand thirty minutes. Add 1 drop of methyl orange T.S., and acidify the mixture by adding a measured excess of half-normal hydrochloric acid. Filter the mixture and wash the precipitate with small portions of distilled water until the washings cease to redden moistened blue litmus paper. Then titrate the excess of hydrochloric acid in the combined filtrates with half-normal sodium hydroxide and subtract the number of cc. of half-normal hydrochloric acid consumed from the number of cc. of half-normal hydrochloric acid used in titrating 25 cc. of the phenylhydrazine solution. The difference, multiplied by 0.05304, gives the weight of benzaldehyde.

This assay is explained on page 1460.

Assay for Hydrocyanic Acid—Dissolve 0.75 Gm. of magnesium sulphate in 45 cc. of distilled water, add 5 cc. of half-normal sodium hydroxide and 2 drops of potassium chromate T.S., and titrate the solution with tenth-normal silver nitrate to the production of a permanent reddish tint. Pour this mixture into a 100 cc. flask, containing about 1 Gm. of Oil of Bitter Almond, accurately weighed, mix well, and titrate again with tenth-normal silver nitrate until a red tint, which does not disappear on shaking, is reproduced. Conduct this titration as rapidly as possible. Each cc. of tenth-normal silver nitrate corresponds to 0.002702 Gm. of hydrocyanic acid.

This assay is explained on page 1464.

Preserve in small, well-stoppered, completely filled, amber-colored bottles, in a cool place, protected from light.

N. F. Preparations—Elixir Amygdalæ Compositum; Elixir Anisi (from Spirit); Spiritus Amygdalæ Amaræ; the N. F. Emulsions.

Uses—Oil of bitter almond is used chiefly as a flavor. It is actively poisonous, as it contains hydrocyanic acid. The dose is one-half minim (0.03 cc.). It must not be used for flavoring foods, but should always be replaced by the natural oil from which the HCN has been removed, or by benzaldehyde, neither of which involve the danger from hydrocyanic acid poisoning.

BENZALDEHYDUM. U.S. Benzaldehyde

[Benzaldehyd.]

Benzaldehyde contains not less than 85 per cent of $C_6H_5.CHO$ (106.08).

Preparation—Artificial benzaldehyde, which is identical with the product obtained from the almond, is now made from toluene, C_7H_8. By the action of chlorine upon the hot toluene, there is produced benzyl chloride, $C_6H_5CH_2Cl$, and benzal chloride, $C_6H_5CHCl_2$, and these yield benzaldehyde upon treatment with manganese dioxide or other oxidizing agents. Artificial benzaldehyde is free from hydrocyanic acid, but is liable to retain traces of chlorine compounds. *This product must not be confounded with nitrobenzene (nitrobenzol), or oil of mirbane, which is made by reaction on benzene with nitric acid.* Nitrobenzene is made in large quantities for perfuming soap, polishing compounds, etc. Its odor is similar to, but by no means identical with, that of oil of bitter almond or benzaldehyde.

Description and Physical Properties—A colorless or yellowish, strongly refractive liquid, having an odor resembling that of oil of bitter almond, and a burning aromatic taste.

Benzaldehyde is soluble in about 350 volumes of water, and is miscible with alcohol, ether, and with fixed or volatile oils.

Tests for Purity—Specific gravity: about 1.045 at 25° C.

Shake 0.5 cc. of Benzaldehyde with 5 cc. of distilled water, add 0.5 cc. of sodium hydroxide T.S. and 0.1 cc. of ferrous sulphate T.S., and warm the mixture gently. Upon the addition to the mixture of a slight excess of hydrochloric acid, no greenish-blue color or blue precipitate is produced within fifteen minutes (*hydrocyanic acid*).

Wind the end of a copper wire into a spiral about 6 mm. in diameter and 6 mm. in length, and hold it in a non-luminous flame until it glows without coloring the flame green. Cool the wire, dip the spiral in the Benzaldehyde, ignite, allow it to burn outside of the flame, and then bring the spiral into contact with the lower, outer edge of the non-luminous flame: not even a transient green color is imparted to the flame (*chlorinated compounds*).

Dissolve 1 cc. of Benzaldehyde in 20 cc. of alcohol, and add distilled water until a slight turbidity is produced. Add zinc and diluted sulphuric acid, maintaining a brisk evolution of hydrogen for one hour. Filter, evaporate the liquid to about 20 cc., and boil 10 cc. of the evaporated liquid with 1 drop of potassium dichromate T.S.: no violet color is produced (*nitrobenzene*).

Assay—Dissolve about 3 cc. of freshly redistilled phenylhydrazine in 60 cc. of alcohol, and titrate 25 cc. of the solution (this solution must always be freshly prepared) with half-normal hydrochloric acid, using 1 or 2 drops of methyl orange T.S. as indicator. To about 1 Gm. of the Benzaldehyde, accurately weighed, add 25 cc. of the phenylhydrazine solution, and allow the mixture to stand for thirty minutes. Add 1 or 2 drops of methyl orange T.S., acidify with a measured excess of half-normal hydrochloric acid, and add 20 cc. of distilled water. Filter, and wash the precipitate with small portions of distilled water until the washings cease to redden blue litmus paper. Titrate the excess of hydrochloric acid in the filtrate with half-normal sodium hydroxide. Subtract the number of cc. of half-normal hydrochloric acid consumed from the number of cc. of half-normal hydrochloric acid used in titrating the 25 cc. of phenylhydrazine solution. The difference, multiplied by 0.05304, indicates the weight of $C_6H_5.CHO$ present.

This assay is explained on page 1460.

Preserve in small, well-stoppered bottles, protected from light.

Uses—Benzaldehyde is used in place of oil of bitter almond for flavoring purposes; it is much safer than the latter because it contains no hydrocyanic acid. The dose is one-half minim (0.03 cc.).

PRUNUS VIRGINIANA. U. S. Wild Cherry

[Prun. Virg.—Wild Black Cherry Bark, Prunus Serotina]

Wild Cherry is the stem bark of *Prunus serotina* Ehrhart (Fam. *Rosaceæ*), collected in autumn and carefully dried. Borke, if present, should be removed.

Description—In curved pieces or irregular fragments, 2 mm. or more thick, outer surface greenish-brown, or yellow-brown, smooth and somewhat glossy, marked with transverse scars; if the bark is collected from old wood and deprived of the corky layer, the outer surface is nut-brown and uneven; inner surface somewhat striate or fissured. Upon maceration in water it develops a distinct bitter-almond odor; its taste is astringent, aromatic, and bitter.

For further description see the U. S. P. X.

U. S. P. Preparations—Syrupus Pruni Virginianæ.

N. F. Preparations—Elixir Taraxaci Compositum (from Fluidextract); Fluidextractum Pruni Virginianæ; Syrupus Pini Albæ Compositus; Syrupus Pini Albæ Compositus cum Morphina.

Uses—This bark contains a glucoside, l-mandelonitrile, emulsin, tannin, bitter principle, starch, resin, etc. This drug will be found referred to in the British Pharmacopœia and in English literature as Virginian Prune—a literal but incorrect translation of the older botanical name.

As with bitter almond, contact with water results in the production of benzaldehyde and hydrocyanic acid; as both of these principles are volatile and active, all preparations of wild cherry should be made without heat. An insoluble precipitate of altered tannin is often noticed in an old fluidextract. Wild cherry is often used in cough syrups but is of little value except as a flavoring agent. Dose, thirty grains (2 Gm.).

ACIDUM HYDROCYANICUM DILUTUM. U. S. P. IX. Diluted Hydrocyanic Acid

[Acid. Hydrocyan. Dil.—Diluted Prussic Acid, Acidum Hydrocyanicum Dilutum P. I.]

An aqueous solution containing not less than 1.9 per cent and not more than 2.1 per cent of HCN (27.02) and not more than 0.1 per cent of HCl. Preserve it in small, dark amber-colored, well-stoppered vials.

Preparation—It may be prepared extemporaneously by the following process:

	Metric	Alternative
Silver Cyanide	**6.00 Gm.**	93 gr.
Diluted Hydrochloric Acid	**15.54 cc.**	252 min.
Distilled Water	**44.10 cc.**	1½ fl. oz.

Mix the diluted hydrochloric acid with the distilled water, add the silver cyanide, and shake the whole together in a glass-stoppered bottle. When the precipitate has subsided, pour off the clear liquid.

Diluted Hydrocyanic Acid may also be made by mixing a solution of potassium ferrocyanide in a retort with diluted sulphuric acid, heating, and then condensing the hydrocyanic acid, collecting it in a well-cooled receiver; the distillate must be assayed and diluted with sufficient water to make a 2 per cent solution.

$$\underset{\text{potassium ferrocyanide}}{(K_4FeCN_6)_2} + \underset{\text{sulphuric acid}}{(H_2SO_4)_6} = \underset{\text{potassium ferrous ferrocyanide}}{K_2Fe_2CN_6} + \underset{\text{potassium acid sulphate}}{(KHSO_4)_6} + \underset{\text{hydrocyanic acid}}{6HCN}$$

Description—A colorless liquid. On account of its poisonous character *it must be handled with great caution.*

Odor and Taste—A characteristic odor resembling that of bitter almond; it is acid to litmus.

Tests for Identity—Render 1 cc. of the Acid alkaline with potassium hydroxide T.S., add a few drops of ferrous sulphate T.S., boil the mixture, and then acidulate with hydrochloric acid; a blue precipitate is formed.

Impurities and Tests for Impurities—Not more than 0.002 Gm. of residue remains on evaporating 10 cc. of Diluted Hydrocyanic Acid to dryness on a water bath.

Hydrogen Chloride—Pour 5 cc. of Diluted Hydrocyanic Acid into a tared, 100 cc. glass-stoppered flask containing 25 cc. of distilled water, accurately determine the weight of the Acid added and then add 50 cc. of tenth-normal silver nitrate and enough distilled water to make 100 cc. Agitate it well and filter through a dry filter, rejecting the first 10 cc. of the filtrate. In 50 cc. of the clear filtrate determine the excess of silver nitrate by titration with tenth-normal potassium

sulphocyanate, previously adding 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. From the number of cc. of tenth-normal silver nitrate consumed in this assay subtract twice the number of cc. of tenth-normal silver nitrate consumed in the assay of the same quantity of diluted Hydrocyanic Acid as ascertained below. The difference when calculated to free hydrogen chloride, using the factor 0.003647, does not amount to more than one-tenth of 1 per cent of the weight of Diluted Hydrocyanic Acid originally taken for the determination.

Assay—Pour about 5 cc. of Diluted Hydrocyanic Acid into a 100 cc. flask containing 25 cc. of distilled water and 5 cc. of potassium hydroxide T.S., the whole having been previously tared, and weigh the Acid accurately. Then add 3 drops of potassium iodide T.S. and titrate with tenth-normal silver nitrate, to the production of a slight permanent precipitate. It shows not less than 1.9 per cent nor more than 2.1 per cent of HCN. Each cc. of tenth-normal silver nitrate V.S. used corresponds to 0.005404 Gm. of HCN. Each gram of Diluted Hydrocyanic Acid corresponds to not less than 3.5 cc. nor more than 3.9 cc. of tenth-normal silver nitrate.

This solution consists of the very poisonous compound HCN in water. *Cyanogen*, CN or Cy, does not exist free in nature, but compounds of it are found in plants and these compounds are called cyanogenetic. It was the first compound radical discovered. It is more closely related to the halogens in the character of its combinations than any other class of bodies. It unites with hydrogen to form hydrocyanic acid, HCN, and its compounds with metals and bases are termed cyanides. These have been considered in previous chapters.

Scheele's hydrocyanic acid is a stronger solution, containing about 5 per cent of the anhydrous acid. Its use should be discouraged as unnecessary, tending to create confusion, and dangerous. Diluted hydrocyanic acid frequently decomposes upon keeping, a black insoluble precipitate (*paracyanogen*) forming in the bottle. This decomposition may be prevented by the addition of a small quantity of hydrochloric acid. The use of cork-stoppered vials is said to be an advantage.

Uses—Diluted hydrocyanic acid is used as a cough sedative in doses of one to three minims (0.05 to 0.2 cc.). Potassium or sodium cyanide is often prescribed in combination with an acid and syrup, so that hydrocyanic acid may be generated and dissolved.

SINAPIS NIGRA. U. S. Black Mustard

[**Sinap. Nig.**—Brown Mustard, Black Mustard Seed, Red Mustard Seed]

Black Mustard is the dried ripe seed of *Brassica nigra* (Linné) Koch and *Brassica juncea* (Linné) Cosson and varieties related to these species (Fam. *Cruciferæ*).

Black Mustard contains not more than 5 per cent of other seeds or other foreign organic matter, and yields not less than 0.6 per cent of volatile oil of mustard (calculated as allyl isothiocyanate).

Description—About 2 mm. in diameter, almost globular, with a circular hilum; testa blackish-brown or grayish-brown, finely pitted, hard; embryo oily, with a curved radicle, and two cotyledons, one folded over the other; free from starch; inodorous when dry, but when triturated with water, of a pungent, penetrating irritating odor; taste pungent and acrid.

For further description see the U. S. P. X.

U. S. P. Preparation—Emplastrum Sinapis.

Black mustard contains *sinigrin* or potassium myronate ($KC_{10}H_{19}NS_2O_{10}$), *myrosin*, a ferment, 25 per cent of fixed oil, mucilage, etc. Under the influence of the myrosin and water, the potassium myronate is converted into *allyl isothiocyanate*, or volatile oil of mustard. This action takes place at ordinary temperature, and explains the pungent odor and taste of aqueous mixtures of ground mustard. *Mustard Plaster* is official (see *Emplastrum Sinapis*)

Uses—It is used as a condiment, stimulant, and emetic; externally, it is rubefacient. When Brown Mustard is prepared as a condiment by the addition of vinegar, salt, and water, the product is known as *German Prepared Mustard*. Both white and black mustard are used in making home made poultices. It is chiefly used as a counter-irritant in the form of "*mustard plasters*", made by mixing it with varying amounts of wheat flour and adding sufficient tepid water to make a paste. It is occasionally used as a gastric and intestinal stimulant. In doses of one to three drachms (4 to 12 Gm.) it is an active, although unpleasant emetic, especially useful in certain poisonings.

SINAPIS ALBA. U.S.P. IX. White Mustard

[Sinap. Alb.—Yellow Mustard]

The ripe seeds of *Sinapis alba* Linné (Fam. *Cruciferæ*), without the presence or admixture of more than 5 per cent of other seeds or other foreign matter.

Official Description—Sub-globular, from 1.5 to 2.5 mm. in diameter; testa yellowish nearly smooth; embryo yellowish, oily, with two large cotyledons.

Odor and Taste—Inodorous, taste mildly pungent, acrid.

Tests for Identity and Purity—The powder is light yellowish or pale brownish-yellow, developing a slight odor when moistened; examined under the microscope, it exhibits numerous tissues of the embryo containing small aleurone grains and a fixed oil, the latter forming in large globules on the addition of chloral hydrate T.S.; fragments of seed-coat comparatively few, nearly colorless, with small characteristic stone cells and large epidermal cells, the outer walls being mucilaginous. The powder contains few or no starch grains.

White Mustard does not yield allyl isothiocyanate upon distillation with steam (distinction from *black mustard*).

White Mustard yields not more than 9 per cent of ash.

Preserve powdered White Mustard in tightly-closed containers.

White mustard seed contains *sinalbin*, $C_{30}H_{44}N_2O_{16}S_2$, a crystalline glucoside, which, under the influence of a peculiar ferment, *myrosin*, and water, is split into *acrinyl isothiocyanate*, C_8H_7NOS, which is a pungent, non-volatile substance (this is not the official oil of mustard), *sinapine sulphate*, $C_{16}H_{23}NO_5H_2SO_4$, and glucose. The seed contains in addition 20 per cent of fixed oil, mucilage, gum, etc., but no starch.

Uses—It is used as a stimulant, condiment, and emetic; externally, it is rubefacient, but it is inferior to the black mustard. Hot water destroys the ferment myrosin, and prevents the development of the pungent principle. The emetic dose is two and one-half drachms (10 Gm.) mixed with a little water.

When prepared as a condiment with vinegar, salt, and water, the product is commonly known as *English Prepared Mustard.*

OLEUM SINAPIS VOLATILE. U.S. Volatile Oil of Mustard

[Ol. Sinap. Vol.—Mustard Oil]

The volatile oil obtained by maceration with water and subsequent distillation of the dried ripe seed (freed from fixed oil) of *Brassica nigra* (Linné) Koch or of *Brassica juncea* (Linné) Cosson (Fam. *Cruciferæ*), or prepared synthetically. The label must state the botanical source or that it was made synthetically.

Volatile Oil of Mustard yields not less than 93 per cent of allyl isothiocyanate [C_3H_5NCS = 99.13].

Caution—Great care must be exercised in smelling this Oil. It should be tasted only when highly diluted.

Preparation—Chemically, this oil is *allyl isothiocyanate*, or *allyl thiocarbamide* $CS.NC_3H_5$; it is also called *allyl sulphocyanide.* Its production is explained in the preceding article. It is prepared artificially by the action of *allyl iodide* upon a solution of *potassium sulphocyanate.*

Description and Physical Properties—A colorless or pale yellow, strongly refractive liquid, having a very pungent, irritating odor, and an acrid taste.

Tests for Identity and Purity—Volatile Oil of Mustard is soluble in all proportions in alcohol, ether, and carbon disulphide.

Specific gravity: 1.013 to 1.020 at 25° C.

Optical rotation: inactive, page 1524.

Refractive index: 1.5268 to 1.5280 at 20° C., page 1525.

An alcoholic solution of the recently distilled oil is neutral to moistened litmus paper.

The addition of 1 drop of ferric chloride T.S. to 1 cc. of the Oil, diluted with 5 volumes of alcohol, does not produce a blue coloration (*phenols*).

The Oil distils completely between 148° and 154° C. Both the first and last 10 per cent portions of the distillate have practically the same specific gravity as the original Oil (*alcohol, chloroform, petroleum, or fatty oils*).

Assay—Dilute about 4 cc. of Volatile Oil of Mustard, accurately weighed, with sufficient alcohol to make exactly 100 cc. Transfer 5 cc. of this solution by means of a pipette to a 100 cc. measuring flask, and add 50 cc. of tenth-normal silver nitrate and 5 cc. of ammonia T.S. Connect the flask to a reflux condenser, and heat it on a bath of boiling water for one hour. Allow the liquid to cool to room temperature, disconnect the flask from the condenser, add sufficient distilled water to measure 100 cc., mix well, and filter. To 50 cc. of the filtrate, accurately measured

add about 5 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate the excess of silver nitrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal silver nitrate corresponds to 0.004957 Gm. of allyl isothiocyanate.

This assay is explained on page 1463.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

N. F. Preparations—Linimentum Sinapis Compositum; Spiritus Sinapis; Unguentum Sinapis.

Uses—Volatile oil of mustard is used as a powerful rubefacient; it must be handled with great care; it is rarely given internally. Dose, one-eighth minim (0.008 cc.).

ALLIUM. N. F. Garlic

Garlic is the fresh bulb of *Allium sativum* Linné (Fam. *Liliaceæ*).

It contains a sulphuretted volatile oil having an exceedingly pungent odor and a strong acrid taste.

Official Description—Bulb sub-globular, from 4 to 6 cm. in diameter, compound, consisting of from eight to fifteen bulbels and surrounded by one or two dry, whitish, membranaceous scales and attached to a flattened circular base, from the lower portion of which arise numerous yellowish-white roots; bulbels more or less ovoid, in transverse section three to four sided, the outer surface being convex, summit acute and narrowed into a thread-like fibrous portion, base, truncate, each bulbel covered by one or two layers of whitish, membranaceous, scale-like leaves, beneath which is the light brown or pinkish, thin and coriaceous layer of epidermis, cohering but easily separable from the solid portion of the bulbel.

Odor and Taste—Odor of broken or bruised bulbels powerfully alliaceous; taste intensely pungent and persistent.

Tests for Identity and Purity—Under the microscope, transverse sections of the bulbel show three distinct portions: (a) the large fleshy scale consisting chiefly of parenchyma enclosing scattered vascular bundles, epidermis in both ventral and dorsal surfaces consisting of small tubular cells; (b) the middle layer nearly circular in outline, about 0.75 mm. in diameter, the tissues resembling those of the outer fleshy scale, but the cells containing numerous yellowish-brown plastids; (c) an innermost bright green layer consisting of a single leaf folded lengthwise along the midrib so that the ventral surfaces lie close together.

N. F. Preparation—Syrupus Allii.

Uses—It is sometimes employed as a rubefacient, carminative and condiment. The syrup is used as an expectorant. The dose is thirty grains (2 Gm.).

Unofficial Nitrogenated or Sulphurated Volatile Oils, Drugs, and Allied Products

Oil of Asafetida	From *Asafetida*. Fam. *Umbelliferæ*. Habitat, Western Tibet. The yield is about 6 to 9 per cent
Bitter Candytuft	*Iberis amare* contains a sulphurated volatile oil
Common Scurvy Grass	From the herb of *Cochlearia officinalis*. Fam. *Cruciferæ*. Habitat, Europe
Cress	The seed of *Lepidium sativum*. Fam. *Cruciferæ*. Contains a sulphurated volatile oil
Oil of Garlic Allyl sulphide $(C_3H_5)_2S$	Obtained artificially by decomposing allyl iodide with an alcoholic solution of potassium sulphide
Hedge Garlic	*Alliaria officinalis*. Fam. *Cruciferæ*. Contains a sulphurated oil
Horseradish	From the root of *Cochlearia Armoracia*. Fam. *Cruciferæ*. Habitat, Europe. The yield is about $\frac{1}{10}$ per cent
Mace (N. F. IV)	The arillode of the seed of *Myristica fragrans* Houttuyn (Fam. *Myristicaceæ*). A flavor and aromatic; dose, eight grains (0.5 Gm.)
Parsley Fruit (U. S. P. IX)	The dried ripe fruit of *Petroselinum sativum* Hoffman (Fam. *Umbelliferæ*). The oleoresin is known as *Apiol*
Parsley Root (N. F. IV)	The dried root of *Petroselinum sativum* Hoffman (Fam. *Umbelliferæ*)
Radish	*Raphanus sativa* contains a sulphurated volatile oil
Sagapenum	From *Ferula persica*. The yield of volatile oil is small
Shepherd's Purse	The seeds of *Capsella bursa-pastoris* contain a sulphurated volatile oil
Wallflower	The seed of *Cheiranthus annuus* contains a sulphurated volatile oil
Wild Mustard	The seed of *Sisymbrium nasturtium* contains a sulphurated volatile oil
Wild Radish	The seed of *Raphanus Raphanistrum* contains a sulphurated volatile oil
Allyl Tribromide $C_3H_5Br_3$	A slightly yellowish liquid, identical with *Tribromhydrin;* sedative and anodyne in its action. Dose, five to six drops
Camphoric Acid $H_2C_{10}H_{14}O_4$ (U. S. P. VIII)	A dibasic organic acid [$C_8H_4(COOH)_2$], obtained by the oxidation of camphor. Used in the treatment of bronchitis and phthisis in doses of fifteen grains (1 Gm.)
Thiosinamin Allyl-sulpho-urea Allyl-sulpho-carbamide $CS\begin{cases}NH_2\\NH(C_3H_5)\end{cases}$	Used in tuberculous diseases, by subcutaneous injection, of four and one-half to seven grains (0.3 to 0.45 Gm.), in 15 per cent alcoholic solution

CHAPTER LXVIII

OFFICIAL DRUGS AND PRODUCTS CONTAINING VOLATILE OIL WITH SOFT RESIN

CUBEBA. U. S. Cubeb

[**Cubeb.**—Cubeb Berries, Java Pepper, Tailed Cubebs, Tailed Pepper]

Cubeb is the dried, nearly full-grown, unripe fruit of *Piper Cubeba* Linné filius (Fam. *Piperaceæ*).

Cubeb contains not more than 5 per cent of its shriveled fruits or stems, not more than 2 per cent of other foreign organic matter, and yields not less than 10 per cent of volatile ether-soluble extractive.

Description—Globular, about 4 to 5 mm. in diameter, contracted at the base into a rounded stipe about 6 or 8 mm. long, reticulately wrinkled, blackish-gray, internally whitish and hollow; odor strong, spicy; taste aromatic and pungent.

Assay—Proceed as directed under volatile ether-soluble extractive, page 1523.

For further description see the U. S. P. X.

N. F. Preparations—Elixir Buchu Compositum (from Compound Fluidextract of Buchu); Fluidextractum Buchu Compositum; Fluidextractum Cubebæ; Oleoresina Cubebæ; Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe; Tinctura Cubebæ.

History—Cubeb, being a close relative of pepper, was originally used as a popular and costly condiment. Later it came to be used as an ingredient in the preparation of the complex antidotal confections called *mithridates*. More than one hundred years ago it was used in a proprietary form of bronchial troche.

Uses—This useful fruit or berry, as it is commonly called, contains about 10 per cent of a volatile oil, 3 per cent of resin, *cubebin*, *cubebic acid*, wax, fat, etc. The virtues of cubeb reside in the cubebic acid, resin, and oil, cubebin when pure being destitute of activity. In dispensing the oleoresin of cubeb, any sediment should be discarded, as it consists of this inert cubebin. Cubebic acid, cubebic resin, and cubebin are all colored red by strong sulphuric acid. Cubeb is used as a stimulant in inflammatory states of the genito-urinary tract. It is also employed in the form of lozenges, for its local stimulating action, in relaxed conditions of the throat. It is sometimes used, either in the form of cigarettes or internally, in bronchitis in doses of fifteen to sixty grains (1 to 4 Gm.).

OLEUM CUBEBÆ. U. S. P. IX. Oil of Cubeb

[**Ol. Cubeb.**—Cubeb Oil]

A volatile oil distilled from the unripe fruit of *Piper Cubeba* Linné filius (Fam. *Piperaceæ*). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light.

Description—A colorless or a pale green to yellowish-green liquid.

Odor, Taste, and Reaction—Characteristic odor and taste of cubeb. Its alcoholic solution is neutral to litmus.

Specific gravity: 0.905 to 0.925 at 25° C.

Test for Identity and Purity—Its optical rotation varies from −20° to −40° in a 100 mm. tube at 25° C. (77° F.).

The oil consists chiefly of sesquiterpenes which distil over between 250° and 280° C., one of which is *cadinene*, $C_{15}H_{24}$, with some dipentene, and probably pinene or camphene. Upon standing, it sometimes deposits rhomboidal prismatic crystals of a stearoptene which is formed by the prolonged action of the air and therefore does not occur in the oil distilled from new berries.

Uses—Oil of cubeb is used for the same purposes as cubeb. Dose, eight minims (0.5 cc.).

CAPSICUM. U. S. Capsicum

[**Capsic.**—Cayenne Pepper, African Chillies, Mexican Pepper, African Pepper, Sierra Leone Pepper, Red Pepper, Chillies, Zanzibar Capsicum, Zanzibar Chillies, Mombassa Chillies, African Bird Pepper]

Capsicum is the dried ripe fruit of *Capsicum frutescens* Linné (Fam. *Solanaceæ*), grown in Africa.

Capsicum contains not more than 3 per cent of its stems, calyxes, and not more than 1 per cent of other foreign organic matter, yields not less than 12 per cent of non-volatile ether-soluble extractive, and not more than 1.25 per cent of acid-insoluble ash.

Description—Oblong-conical, from 10 to 25 mm. long, supported by a flattish, cup-shaped, five-toothed calyx, with a red, shining, membranous and translucent pericarp, enclosing two cells and containing flat, reniform, yellowish seeds attached to a thick, central placenta. It has a peculiar odor, and an intensely hot taste.

Capsicum should meet the requirements of the following test: Mix well 1 Gm. of powdered Capsicum in 50 cc. of alcohol in a stoppered flask and macerate for twenty-hour hours. Dilute 0.1 cc. of the clear, supernatant liquid with 140 cc. of distilled water containing 10 per cent of sucrose; 5 cc. of this dilution swallowed at once will produce a distinct sensation of the pungency of Capsicum in the throat of at least two out of three individuals.

Assay—For non-volatile ether-soluble extractive proceed as directed on page 1523.

For further description see the U. S. P. X.

U. S. Preparations—Oleoresina Capsici; Tinctura Capsici.

N. F. Preparations—Mistura Chloroformi et Morphinæ Composita (from Tincture); Mistura Opii et Chloroformi Composita (from Tincture); Mistura Opii et Rhei Composita (from Tincture); Pulvis Aromaticus Rubefaciens; Pulvis Myricæ Compositus; Tinctura Capsici et Myrrhæ.

The principal constituents of capsicum are capsaicin, $C_9H_{14}O_2$, traces of a volatile alkaloid and a volatile oil, fixed oil, resin, coloring matter, etc. *Capsaicin* is in colorless crystals, volatile, intensely acrid, and soluble in alcohol, ether, and fixed oils.

Uses—Capsicum is used internally as a gastric and intestinal stimulant. Externally it is much used as a rubefacient and is the basis of numerous liniments and stimulating salves. Dose, one grain (0.06 Gm.).

COPAIBA. U. S. Copaiba

[**Copaib.**—Balsam of Copaiba, Copaiva, Balsam Capaiba, Balsam Capaiva]

An oleoresin derived from South American species of *Copaiba* (Fam. *Leguminosæ*).

Copaiba is mostly imported from Para in Brazil, Maracaibo in Venezuela, and other South American ports. It contains *copaivic acid*, a volatile oil, and a bitter principle. Copaivic acid, $C_{20}H_{30}O_2$, the resinous mass left after distilling the oil, forms a series of amorphous salts. (See Massa Copaibæ.) It may be obtained pure by exposing a mixture of nine parts of copaiba and two parts of aqueous ammonia (sp. gr. 0.95) to a temperature of 10° C. Copaiba is often adulterated.

Oil of copaiba was official in the U. S. P. VIII and was described as a colorless or pale yellow liquid having the characteristic odor of copaiba and an aromatic, slightly bitter and pungent taste. The specific gravity is from 0.985 to 0.905 at 25° C., increasing with age. It is levogyrate. It is used as a stimulant, and for the same purposes as copaiba. Dose, five to ten minims (0.3 to 0.6 cc.).

The U. S. P. description and tests for Copaiba are as follows:

Description and Physical Properties—A pale yellow to brownish-yellow, more or less viscid liquid, either without fluorescence or with only a slightly greenish fluorescence. It has a peculiar aromatic odor, and a persistent, bitter, acrid taste.

Copaiba is insoluble in water, partly soluble in alcohol, more completely soluble in dehydrated alcohol. It is soluble in carbon disulphide and in fixed or volatile oils, completely soluble in chloroform and in ether; also soluble in an equal volume of petroleum benzin, the further addition of the solvent producing a flocculent precipitate.

Specific gravity: 0.940 to 0.995 at 25° C.

Tests for Purity—Heat about 2 Gm. of Copaiba, accurately weighed, in a shallow dish on a water bath: no odor of oil of turpentine is evolved. Continue the heating until all of the volatile oil has been driven off; a resin remains, corresponding to not less than 36 per cent of the original weight of the Copaiba taken. This resin when cooled is hard and brittle (*paraffin or fatty oils*). Its acid number is not less than 28 and not more than 95, page 1512.

Shake 5 cc. of Copaiba with 15 cc. of alcohol, boil the mixture for one minute, and cool: no oil separates after standing for one hour (*paraffin oils*).

Mix one drop of nitric acid and 3 cc. of glacial acetic acid in a test tube, and carefully add four drops of the oil separated from the Copaiba by distillation with steam; no reddish zone appears, nor does the liquid become red or purple after being shaken (*gurjun balsam*).

Dissolve 2 Gm. of Copaiba in 40 cc. of dehydrated alcohol, filter on counterbalanced filters or with the aid of a Gooch crucible, and wash with small portions of dehydrated alcohol until the washings are colorless or nearly so: the residue dried at 80° C. does not exceed 5 per cent.

The volatile oil separated from Copaiba by distillation with steam does not boil below 250° C., and shows an angle of rotation in a 100 mm. tube of not less than −7° at 25° C. (*African copaiba*).

N. F. Preparations—Massa Copaibæ; Mistura Copaibæ; Mistura Copaibæ et Opii.

Uses—Copaiba has a stimulant action upon the mucous membranes of the urinary passages. Dose, from fifteen minims to one fluidrachm (1 to 4 cc.).

MASSA COPAIBÆ. N. F. Mass of Copaiba

See page 488 for the formula and uses.

SANTALUM ALBUM. N. F. Sandalwood

[**Santal. Alb.**—White Sandalwood, Yellow Sandalwood]

Sandalwood is the heart-wood of *Santalum album* Linné (Fam. *Santalaceæ*).

Sandalwood yields not less than 3.5 per cent of volatile oil and contains not more than 1 per cent of foreign organic matter. It contains a volatile oil (see *Oleum Santali*).

Description—In billets, pieces or chips of varying shapes and sizes, heavy, hard but splitting easily, color light yellow to light brown. Odor characteristic, aromatic, persistent; taste peculiar strongly aromatic.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Santali Albi; Tinctura Sabal et Santali.

Uses—Used as a perfume, especially in sachet powders.

OLEUM SANTALI. U. S. Oil of Santal

[**Ol. Santal.**—Santalwood Oil, Oil of Sandalwood]

The volatile oil distilled from the dried heart-wood of *Santalum album* Linné (Fam. *Santalaceæ*).

Oil of Santal yields not less than 90 per cent of alcohols calculated as santalol [$C_{15}H_{24}O = 220.27$].

Description and Physical Properties—A pale yellow, somewhat viscid, oily liquid, having the characteristic odor and taste of sandalwood.

Tests for Identity and Purity—The Oil is soluble in 5 volumes of 70 per cent alcohol, by volume.

Specific gravity: 0.965 to 0.980 at 25° C.

Optical rotation: varies from −15° to −20° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.5040 to 1.5080 at 20° C., page 1525.

A solution of the recently distilled Oil in 70 per cent alcohol (1 in 5) is slightly acid to moistened blue litmus paper.

Assay—Proceed as directed for total menthol under *Oleum Menthæ Piperitæ*, page 1461, using 10 cc. of Oil of Santal. Use the following formula in calculating the per cent of santalol.

$$\text{Per cent of santalol} = \frac{A \times 11.01}{B - (A \times 0.021)}$$

A is the result obtained by subtracting the number of cc. of half-normal sulphuric acid required in the titration from the number of cc. of half-normal alcoholic potassium hydroxide originally taken, and *B* is the weight of the acetylized oil taken.

This assay is explained on page 1461.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

This is an oxygenated oil containing two constituents, one of which is called *santalol*, $C_{15}H_{26}O$, boiling at 310° C., and the other *santalal*, $C_{15}H_{24}O$, boiling at 300° C. Both of these are decomposed by distilling over phosphoric anhydride, the one yielding $C_{15}H_{24}$, boiling at 260° C., and the other $C_{15}H_{22}$, boiling at 245° C. Sesquiterpenes are also believed to be present in oil of santal. It is often grossly adulterated; the proportion of santalol is recognized by an official assay (see above).

Uses—It is eliminated chiefly by the kidneys and is a fairly effective urinary antiseptic. It is used particularly in subacute or chronic urethritis and cystitis. The oil, at times, is disturbing to the stomach and medicinal doses may cause irritation of the bladder with dysuria and pain in the kidney region and urethra. It is also less frequently employed in bronchitis. It is generally administered in capsules or pearls. Dose, five to fifteen minims (0.3 to 1 cc.).

Spurious oils are sometimes sold under the name of *West India Sandalwood Oil*. An *Australian Sandalwood* oil has recently been introduced largely for perfumery purposes. It is being used abroad to some extent medicinally but has not been recognized by the U. S. P.

Unofficial Sandalwood Oil Derivatives

The advantage claimed for the new derivatives of santal oil is that they are less irritating than the oil itself.

Arheol, N.N.R.—Santalol—A sesquiterpenic alcohol, the chief constituent of sandalwood oil. Arheol contains not less than 98 per cent of santalol.

Arheol Capsules—Arheol 0.2 Gm. (3 grains).

A colorless, oily liquid; specific gravity about 0.968 at 15° C. It is insoluble in water but soluble in alcohol. It boils under 11 mm. pressure at 169° C., and under ordinary pressure at about 300° C.

Uses—The action of Arheol is the same as that of sandalwood oil. It is used in urethritis, cystitis and vesical catarrh, especially from gonorrhea.

The dose is from 6 to 10 grains (0.4 to 0.6 Gm.).

Manufactured by P. Astier Laboratories, Paris and New York (George J. Wallau, Inc., New York).

Santyl, N.N.R.—Santalolis Salicylas—Salicylic Ester of Santalol—Santalyl Salicylate—$C_6H_4OH.COO(C_{15}H_{23})$—The salicylic acid ester of santalol.

Uses—It is said that Santyl passes the stomach unchanged, but is slowly split up in the intestines into its constituents, santalol and salicylic acid. Santyl is claimed to have the same action as sandalwood oil, except that because of the slow liberation of santalol, it produces less irritation of the gastro-intestinal tract or of the kidneys and urinary passages, and no unpleasant odor or eructations.

It is claimed to be useful in the same manner as santal oil for gonorrheal urethritis.

The dose is 24 minims (1.5 cc.), usually given in 4 capsules of 6 minims each, three times a day. It is incompatible with alkalies and with the usual incompatibilities of the sandalwood oil and of salicylates.

Manufactured by E. Bilhuber, Inc., New York.

BUCHU. U.S. Buchu

[Buchu Leaves, Long and Short Buchu, Bookoo]

Buchu is the dried leaf of *Barosma betulina* (Thunberg) Bartling et Wendland, or of *Barosma crenulata* (Linné) Hooker, known in commerce as Short

Buchu; or of *Barosma serratifolia* (Curtis) Willdenow, known in commerce as Long Buchu (Fam. *Rutaceæ*).

Buchu contains not more than 8 per cent of its stems and not more than 2 per cent of other foreign organic matter.

Description—*Short Buchu*—Rhomboidally oval or obovate from 9 to 30 mm. in length and from 4 to 20 mm. in breadth; apex obtuse or rounded and sometimes recurved, base wedge-shaped or obtuse, margin finely dentate, glandular punctate, with an oil gland at the base of each tooth, papillose, longitudinally striate beneath, coriaceous and with a petiole about 1 mm. in length: color bright green to yellowish-green, occasionally olive-gray; odor aromatic and mint-like; taste camphoraceous.

Long Buchu—Linear-lanceolate from 12 mm. to 4 cm. in length and from 4 to 10 mm. in breadth; apex acute, somewhat rounded; margin sharply serrate. Otherwise resembles Short Buchu.

U. S. P. Preparation—Fluidextractum Buchu.

N. F. Preparations—Elixir Buchu (from Fluidextract); Elixir Buchu Compositum (from Compound Fluidextract); Elixir Buchu et Potassii Acetatis (from Elixir of Buchu); Fluidextractum Buchu Compositum.

This drug owes its valuable properties to the presence of a volatile oil and a resin. It also contains a bitter principle, mucilage, etc. The stearoptene, *diosphenol*, is colored dark green by ferric chloride.

Uses—Buchu is used chiefly in cystitis. Dose, thirty grains (2 Gm.).

SERPENTARIA. U. S. Serpentaria

[**Serpent.**—Texas Snakeroot, Virginia Snakeroot]

Serpentaria consists of the dried rhizome and roots of *Aristolochia Serpentaria* Linné, known in commerce as Virginia Snakeroot, or of *Aristolochia reticulata* Nuttall, known in commerce as Texas Snakeroot (Fam. *Aristolochiaceæ*).

Serpentaria contains not more than 10 per cent of its over-ground stems and not more than 2 per cent of other foreign organic matter, and yields not more than 10 per cent of acid-insoluble ash.

Description—The rhizome is about 25 mm. long, thin, bent; on the upper side with approximate, short stem-bases; on the lower side with numerous, thin, branching roots about 10 cm. long; dull yellowish-brown, internally whitish; the wood-rays of the rhizome longest on the lower side; odor aromatic, camphoraceous; taste warm, bitterish, and camphoraceous.

For further description see the U. S. P. X.

U. S. P. Preparation—Tinctura Cinchonæ Composita.

N. F. Preparations—Fluidextractum Serpentariæ; Tinctura Serpentariæ.

This rhizome, when fresh, contains 1 per cent of volatile oil, a bitter principle, starch, sugar, etc. It yields its virtues to hydroalcoholic menstrua.

Uses—It is a bitter tonic. Dose, fifteen grains (1 Gm.).

CANNABIS. U. S. Cannabis

[**Cannab.**—Cannabis Indica, Guaza, Ganjah, Bhang, Hasheesh, Charas, Indian Hemp, Hemp, American Indian Hemp, Foreign Indian Hemp, Bangue Hemp, Halish (with specification as to origin), Cannabis American Indian Hemp]

Cannabis is the dried flowering tops of the pistillate plants of *Cannabis sativa* Linné (Fam. *Moraceæ*).

Cannabis, in the form of the fluidextract, administered by the mouth to dogs in doses not exceeding 0.1 cc. for each kilogram of body weight of dog, produces a degree of incoördination equivalent to that caused by the same dose of the standard fluidextract of cannabis, prepared as directed on page 408. It contains not more than 10 per cent of its fruits, large foliage leaves, stems over 3 mm. in diameter, and not more than 2 per cent of other foreign organic

matter. It yields not more than 5 per cent of acid-insoluble ash, and not less than 8 per cent of alcohol-soluble extractive.

Description—In separate tops or more or less agglutinated masses or fragments, consisting of the short stems with their leaf-like bracts and pistillate flowers or more or less developed fruits; color green to dark green or greenish-brown; odor agreeable, somewhat heavy and narcotic; taste somewhat acrid and pungent.

Leaves digitately compound, usually broken. Leaflets when entire, linear lanceolate, nearly sessile, margin deeply serrate. Bracts ovate, pubescent, each enclosing 1 or 2 pistillate flowers or more or less developed fruits. Calyx dark green, pubescent and somewhat folded around the ovary. Styles, 2, filiform and pubescent. Ovary with a single campylotropous ovule. Stems cylindrical, longitudinally furrowed, light green to light brown, strigose-pubescent.

Structure of Stem—Cortex composed of collenchyma and, in the larger stems, of numerous strands of more or less lignified bast-fibers; strongly lignified wood with medullary rays 1-cell wide; pith, often hollow; rosette aggregates of calcium oxalate numerous.

Assay—Prepare a fluidextract and proceed as directed under Biological Assays (Chapter LXXXIX).

The details of this assay and an explanation will be found on page 1507.

U. S. P. Preparations—Extractum Cannabis; Fluidextractum Cannabis.

N. F. Preparations—Collodium Salicylici Composita (from Fluidextract); Mistura Chlorali et Potassii Bromidi Composita (from Extract); Mistura Chloroformi et Morphinæ Composita (from Tincture); Tinctura Cannabis.

Cannabis contains a resinous substance, *cannabinine*, volatile oil, *cannabinol*, and *tetanocannabinine*. Alcohol is the best solvent for the active principles. The Pharmacopœia has permitted the use of cannabis sativa, no matter where grown, provided it conforms to the biological standard. Much cannabis is now cultivated in America and in tropical countries. The standardization of the drug and all of its preparations is required.

Uses—It is used as an anodyne and nerve sedative. Dose, one grain (0.06 Gm.).

VALERIANA. U. S. Valerian

[**Valer.**—Garden Valerian]

Valerian consists of the dried rhizome and roots of *Valeriana officinalis* Linné (Fam. *Valerianaceæ*).

Valerian contains not more than 5 per cent of foreign organic matter and yields not more than 10 per cent of acid-insoluble ash.

Description—Rhizome from 2 to 4 cm. long, and 1 to 2 cm. thick, upright, sub-globular or obconical, truncate at both ends, brown or yellowish-brown, internally whitish or pale brownish, with a narrow circle of white wood under the thin bark. Roots numerous, slender, brittle, brown, with a thick bark, and slender ligneous cord. Odor peculiar, becoming stronger and unpleasant on keeping; taste camphoraceous and somewhat bitter.

For further description see the U. S. P. X.

U. S. P. Preparations—Tinctura Valerianæ; Tinctura Valerianæ Ammoniata.

N. F. Preparation—Fluidextractum Valerianæ.

Valerian contains about 1 per cent of volatile oil, valeric acid, resin, starch, tannin, etc.; there are also present some acetic and formic acids. Alcohol and ether are good solvents for the active principles.

Uses—It is used as a nervine. Dose, thirty grains (2 Gm.).

OLEUM CHENOPODII. U. S. Oil of Chenopodium

[**Ol. Chenopod.**—Oil of American Wormseed]

The volatile oil distilled with steam from the fresh, over-ground parts of the flowering and fruiting plant of *Chenopodium ambrosioides* var. *anthelminticum* (Linné) A. Gray (Fam. *Chenopodiaceæ*). Oil of Chenopodium yields not less than 65 per cent of ascaridol [$C_{10}H_{16}O_2$ = 168.18].

Description and Physical Properties—A colorless or pale yellowish liquid, having a peculiar, disagreeable odor, and a bitter, burning taste.

Tests for Identity and Purity—The Oil is soluble in not more than 8 volumes of 70 per cent alcohol, by volume.

Specific gravity: 0.955 to 0.980 at 25° C.

Optical rotation: varies from −4° to −10° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4723 to 1.4770 at 20° C., page 1525.

The Oil meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

Assay—Place 10 cc. of Oil of Chenopodium, measured from a pipette, in a 100 cc. cassia flask, add 50 cc. of a solution of acetic acid, made by diluting 60 cc. of glacial acetic acid with distilled water, to measure 100 cc. Shake the mixture well, add sufficient of the acetic acid solution to raise the lower limit of the oily layer within the graduated portion of the neck, and allow the liquids to separate, rotating the flask from time to time. Note the volume of the oily layer. It measures not more than 3.5 cc., indicating the presence of not less than 65 per cent by volume of ascaridol.

This assay is explained on page 1483.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

This oil consists of two distinct portions, separable by distillation; one of these has the formula $C_{10}H_{16}$, and is probably limonene; the other is heavier and possesses the formula $C_{10}H_{16}O_2$. This constitutes over 50 per cent of the commercial oil and has been given the name *ascaridol*, which is an unstable organic oxide, decomposing with explosive violence with inorganic acids.

Uses—It is used as an anthelmintic, and is best administered as an emulsion, first mixing the oil with twice its volume of olive oil. Its taste is so offensive to children, to whom it is almost exclusively given in the treatment against intestinal worms, that the emulsion should be flavored with methyl salicylate, aromatic oils, or other substances. The oil has caused death in doses of half a fluidrachm. In some cases the diluted oil may be given in capsules. Dose, fifteen minims (1 cc.).

OLEUM JUNIPERI. U. S. Oil of Juniper

[Ol. Junip.—Juniper Oil, Oil of Juniper Berries]

The volatile oil distilled from the dried ripe fruit of *Juniperus communis*, Linné (Fam. *Pinaceæ*).

Description and Physical Properties—A colorless or faintly green or yellow liquid, having the characteristic odor and taste of juniper berries.

Tests for Identity and Purity—The Oil is soluble in 4 volumes of alcohol, with not more than a slight cloudiness.

Specific gravity: 0.854 to 0.879 at 25° C.

Optical rotation: varies from 0° to −15° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4790 to 1.4840 at 20° C., page 1525.

A solution of the recently distilled Oil in alcohol (1 in 4) is neutral or only slightly acid to moistened litmus paper.

The Oil meets the requirements of the test for *heavy metals in volatile oils*, page 1519.

Preserve in well-stoppered, completely filled, amber-colored bottles, in a cool place, protected from light.

Oil of juniper (berries) is composed essentially of two hydrocarbons, the more abundant of which, boiling at 160° C., has been shown by Wallace to be *pinene*, $C_{10}H_{16}$. Above 175° C. another oil is obtained, which seems to be *cadinene*, $C_{15}H_{24}$. It also contains a small amount of an ester to which the peculiar juniper-like odor and taste was supposed to be due, but this cannot be the case, as the odor persists after the complete saponification of the small amount of ester. *Juniper camphor* is also present, its melting point being 165° to 166° C. It was formerly used in making the spirit and compound spirit of juniper (see page 315).

N. F. Preparation—Acetum Aromaticum.

Uses—It has diuretic and stimulant properties. Dose, one and one-half minims (0.1 cc.).

ARALIA. N. F. Aralia

[**Aral.**—American Spikenard, Spignet]

Aralia is the dried rhizome and root of *Aralia racemosa* Linné (Fam. *Araliaceæ*).

Aralia contains not over 5 per cent of its stems, bases, or other foreign organic matter.

Description—Rhizome of oblique growth, about 12 cm. in length and 5 cm. in thickness, somewhat flattened, tortuous, externally pale brown, somewhat annulately roughened, frequently cut longitudinally, whitish internally; nodes approximate, each with a prominent stem scar about 3 cm. in breadth; fracture fibrous; roots numerous, of varying length, from 5 to 25 mm. in thickness, usually cut longitudinally and furrowed, sometimes with transverse ridges and corky patches; light brown or purplish-brown externally, whitish and spongy or porous internally; fracture of the cortex short, of the wood short and fibrous. Odor aromatic; taste mucilaginous, pungent, and slightly acrid.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Araliæ; Syrupus Pini Albæ Compositus; Syrupus Pini Albæ Compositus cum Morphina.

The principal constituents are resin, a little volatile oil, starch, and pectin.

Uses—A mild aromatic and diaphoretic. Dose, thirty grains (2 Gm.).

CANELLA. N. F. Canella

[**Canel.**—White Cinnamon, Wild Cinnamon]

Canella is the dried rossed bark of *Canella Winterana* (Linné) Gaertner (Fam. *Canellaceæ*).

Canella contains not more than 2 per cent of foreign organic matter. It contains an acrid volatile oil, resin, and a bitter extractive.

Description—In quills usually from 1 to 3 cm. in length and from 1 to 4 cm. in thickness, occasionally two or three times this size, or in irregular fragments of quills, from 1.5 to 5 mm. in thickness and 2 to 3 cm. in width, the outer periderm mostly removed; outer surface light brownish-yellow or pale orange-brown, more or less scaly with a few very shallow fissures, often more or less reticulate with slight ridges; inner surface paler, somewhat smooth, but showing coarse, longitudinal striæ; fracture short and sharp, pale yellow, with an irregular, slightly darker band just inside of the center. Odor slight unless the bark is heated, then aromatic, resembling that of cinnamon; taste aromatic, warm, somewhat bitter and mucilaginous.

For further description see the N. F. V.

N. F. Preparation—Pulvis Aloes et Canellæ.

Uses—A mild, aromatic tonic in doses of thirty grains (2 Gm.).

GALANGA. N. F. Galangal

[East India Root, East India Catarrh Root]

Galangal is the dried rhizome of *Alpina officinarum* Hance (Fam. *Zingiberaceæ*).

Description—Irregularly branched, from 2 to 10 cm. in length and from 1 to 2 cm. in thickness, the branches thinner toward the base; marked with the fine annuli of the leaf bases, which are from 3 to 10 mm. apart and of lighter color than the general surface; externally reddish- or rusty-brown; internally of a lighter orange-brown; cut ends of the branches circular, with recurved margin; fracture fibrous. Odor aromatic and agreeable; taste hot, spicy, resembling ginger.

N. F. Preparation—Tinctura Aromatica.

It contains about 0.5 per cent of a volatile oil, containing cineol, also a soft acrid resin, a fixed oil, and certain active principles known as *galangin*, $C_{15}H_{10}O_5$, and *galangol*.

Uses—Employed as an aromatic and carminative. The dose is fifteen grains (1 Gm.).

HUMULUS. N. F. Hop

(U. S. P. IX)

[**Humul.**]

Hop is the carefully dried strobile of *Humulus Lupulus* Linné (Fam. *Moraceæ*), bearing their glandular trichomes. Hop contains not more than 2 per cent of stems, leaves, or other foreign matter, and yields not more than 5 per cent of acid-insoluble ash.

Description—Ovate, about 3 cm. long, consisting of a thin, hairy, undulated axis, and many obliquely ovate, membranous scales, in the upper part reticulately veined, and towards the base parallel-veined, glandular, and surrounding a sub-globular achene; color of the scales greenish, free from reddish or brownish spots; odor aromatic; taste bitter, aromatic, and slightly astringent.

For further description see the N. F. V.

Uses—Hops are an aromatic bitter, useful in atonic dyspepsia. Dose, thirty grains (2 Gm.).

IRIS. N. F. Orris

[Orris Root, Florentine Orris, Verona Orris]

Orris is the dried rhizome of *Iris florentina* Linné, *Iris germanica* Linné, or *Iris pallida* Lamarck (Fam. *Iridaceæ*), freed from the roots, peeled, and dried.

Orris contains not more than 1 per cent of foreign organic matter.

It contains a peculiar, fat-like volatile oil and a soft, acrid resin. The oil is known as *orris butter* and contains the ketone *irone*. It also contains a glucoside *iridin*, $C_{24}H_{26}O_{13}$.

Description—In pieces of various forms and sizes, usually jointed and branched, from .5 to 10 cm. in length and from 1.5 to 3 cm. in width, rounded or flattened, with knotty enlargements; under surface shows numerous root scars, the upper with leaf scars; externally yellowish-white; internally light yellow; fracture hard, rough and at times mealy, showing a narrow cortex, a distinct endodermis and a large stele with numerous fibro-vascular bundles, especially near the endodermis. Odor fragrant, resembling that of violet flowers; taste slightly aromatic, bitterish, somewhat irritating.

For further description see the N. F. V.

N. F. Preparation—Species Pectorales.

Uses—Rarely employed in medicine, although it has been used as a diuretic and errhine. Largely used in perfumery and tooth preparations.

JUNIPERUS. N. F. Juniper Berry

[**Junip.**—Horse Savin Berries]

Juniper berry is the carefully dried, ripe fruit of *Juniperus communis* Linné (Fam. *Pinaceæ*). Juniper Berry contains not more then 10 per cent of immature or discolored berries and not more than 3 per cent of foreign organic matter.

They contain a volatile oil which is official, also about 10 per cent of resin, and a yellow coloring matter called *juniperin*.

Description—Nearly globular, about 8 mm. in diameter; externally smooth, shining black-brown to purplish-black with a blue-gray bloom, at the apex a three-rayed furrow marks the cohesion of the three fleshy bracts forming the pericarp; internally loosely fleshy, greenish-brown, containing numerous large schizogenous cavities; seeds three, triangular ovate, hard, brown, with large uneven oil glands on the surface. Odor aromatic; taste sweet, pleasant, terebinthinate, slightly bitter.

For further description see the N. F. V.

N. F. Preparation—Elixir Buchu Compositum (from Compound Fluidextract of Buchu); Fluidextractum Buchu Compositum; Fluidextractum Juniperi.

Uses—A stimulant diuretic in doses of one drachm (4 Gm.).

LUPULINUM. N. F. Lupulin

Lupulin consists of the glandular trichomes separated from the strobiles of *Humulus Lupulus* Linné (Fam. *Moraceæ*).

Lupulin yields not less than 60 per cent of ether-soluble extractive and not more than 10 per cent of acid-insoluble ash.

Description—Bright brownish-yellow, becoming yellowish-brown, resinous, consisting of minute granules, which, as seen under the microscope, are sub-globular, or rather hood-shaped, and reticulate; aromatic and bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Lupulini.

Lupulin contains 10 per cent of volatile oil, which, on exposure, yields valeric acid trimethylamine, a bitter principle (lupamaric acid), $C_{82}H_{50}O_7$, resin, wax, and an alkaline liquid termed *lupuline*. Alcohol and ether are the best solvents. An oleoresin was official in the N. F. IV (see page 447).

Uses—As an antispasmodic and nerve sedative. Dose, five to eight grains (0.3 to 0.5 Gm.).

MATICO. N. F. Matico

[**Matic.**]

Matico is the dried leaf of *Piper angustifolium* Ruiz et Pavon (Fam. *Piperaceæ*).

Matico contains not more than 5 per cent of stems, flower spikes, or other foreign organic matter, and yields not more than 6 per cent of acid-insoluble ash.

Matico leaves contain about 2 per cent of volatile oil, a pungent resin, a crystalline principle, *artanthic acid*, and tannin.

Description—Usually in compressed, matted masses with leaves more or less broken; leaves sub-sessile, lanceolate, from 10 to 20 cm. in length and from 2 to 5 cm. in breadth; summit tapering and acute; base slightly unequal, cordate, margin finely crenulate; upper surface dark green, tesselated; lower surface pale green, reticulate, with prominent, yellowish-brown midrib and veins forming small quadrangular meshes clothed with matted pubescence. Odor distinct, aromatic; taste pungent, pepper-like.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Matico.

Uses—It is used as a stimulant and hemostatic in doses of one drachm (4 Gm.).

MYRICA. N. F. Bayberry Bark

[**Myric.**—Wax Myrtle Bark, Candleberry Bark]

Bayberry bark is the dried bark of the root of *Myrica cerifera* Linné or *Myrica caroliniensis* Miller (Fam. *Myricaceæ*).

Bayberry bark contains not more than 5 per cent of adhering wood or other foreign organic matter.

It contains volatile oil, an acrid resin, tannin, and *myricinic acid.*

Description—In quills or quilled pieces or strips, of variable length and up to 20 mm. in breadth, the bark rarely exceeding 2 mm. in thickness; outer surface varying from dark brown to gray-brown, occasionally slightly silvery, somewhat lustrous, at least in patches, bearing occasional warts or slight transverse ridges, the periderm frequently much wrinkled; inner surface deep rusty-brown, finely short-striated and somewhat roughened; fracture short and weak, light brown in the outer layer, yellowish-brown in the inner layer. Odor characteristic, rather disagreeable; taste astringent, mildly bitter and slightly acrid.

For further description see the N. F. V.

N. F. Preparation—Pulvis Myricæ Compositus.

Uses—It is a sialogogue when chewed and has been used in toothache. It is an active errhine and has been employed as a tonic and astringent in doses of eight grains (0.5 Gm.).

PIPER. N. F. Pepper

(U. S. P. IX)

[Black Pepper]

Pepper is the dried, unripe fruit of *Piper nigrum* Linné (Fam. *Piperaceæ*). Pepper contains not more than 2 per cent of stems or other foreign matter.

Description—Globular, about 4 mm. in diameter, reticulately wrinkled, brownish-black or grayish-black, internally lighter, hollow, with an undeveloped embryo; odor aromatic; taste pungently spicy.

For further description see the N. F. V.

N. F. Preparations—Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe.

Black pepper contains piperine, 2 per cent of volatile oil, and a pungent resin soluble in alcohol and in ether. The oleoresin was formerly official, see page 447. The volatile oil is a terpene, $C_{10}H_{16}$.

Uses—The principal use of pepper is as a condiment and intestinal stimulant, and for the making of the oleoresin. Dose, eight grains (0.5 Gm.).

Piperine was official in the U. S. P. VIII and was described as a feebly basic substance ($C_{17}H_{19}NO_3$), obtained from pepper and other plants of the *Piperaceæ*. It is obtained by treating pepper with alcohol, evaporating the tincture to the consistence of an extract, submitting the extract to the action of an alkaline solution, by which the oleaginous matter is converted into soap, washing the undissolved portion with cold water, separating the liquid by filtration, treating the matter left on the filter with alcohol, and allowing the solution thus obtained to evaporate spontaneously, or by a gentle heat. Crystals of piperine are deposited and may be purified by alternate solution in alcohol or ether and crystallization. Piperine is decomposed by alkalies in alcoholic solution into *piperic acid*, $C_{12}H_{10}O_4$, and *piperidine*, $C_5H_{11}N$. It is considered to be an alkaloid of feeble power. It consists of colorless or pale yellowish, glistening, monoclinic crystals; permanent in the air and containing no water of crystallization. Optically inactive. When put into the mouth, it is at first tasteless, but on prolonged contact develops a sharp, biting taste; odorless; neutral reaction; insoluble in water; soluble in 15 parts of alcohol at 25° C.; in 4.4 parts of alcohol at 60° C.; also soluble in 36 parts of ether and 1.7 parts of chloroform at 25° C.

Uses—Piperine has been used as a stimulant and as an antiperiodic. When absolutely pure it has but little medicinal action. Dose, three grains (0.2 Gm.).

POPULI GEMMÆ. N. F. Balsam Poplar Buds

[**Popul. Gem.**—Balm of Gilead Buds, Black Poplar Buds, Willow Poplar Buds]

Balsam Poplar Buds consist of the air-dried, closed, winter leaf-buds of *Populus nigra* Linné or *Populus candicans* Aiton, or *Populus balsamifera* Linné (Fam. *Salicaceæ*).

Balsam Poplar Buds contain not more than 10 per cent of flower buds and yield not more than 1 per cent of acid-insoluble ash.

They contain volatile oil and resin.

Description—Conical, pointed, up to 2 cm. in length and from 2 to 5 mm. in thickness, consisting of closely imbricated scales, externally brown and glossy, glutinous with fragrant resin. Odor pleasant, balsamic; taste aromatic and bitter.

N. F. Preparations—Syrupus Pini Albæ Compositus; Syrupus Pini Albæ Compositus cum Morphina.

Uses—A stimulating expectorant; also used in an ointment for application to sluggish sores.

SAMBUCUS. N. F. Sambucus

[**Sambuc.**—Elder Flowers]

Sambucus is the air-dried flowers of *Sambucus canadensis* Linné or of *Sambucus nigra* Linné (Fam. *Caprifoliaceæ*).

Sambucus contains not more than 2 per cent of foreign organic matter.

It contains small amounts of volatile oil, resin, sugar, and mucilage.

Description—Small, from 2 to 3 mm. in breadth, shriveled; calyx superior, five-lobed; corolla cream colored to brownish-yellow, rotate, flat, or slightly campanulate, regularly five-lobed; stamens five inserted at the base of the corolla and alternating with its lobes, filaments slender, anthers oblong, yellow; pollen ellipsoidal or tetrahedral and rounded, covered with finely punctate markings and having three pores. Odor faintly sweet and aromatic; taste slightly bitter.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Stillingiæ Compositum; Species Laxativæ.

Uses—It has little medicinal virtue, but is used in domestic practice in the form of infusion, ointment, or poultice, and for preparing *elder flower water* by distillation.

THUJA. N. F. Thuja

[Arbor Vitæ, White Cedar]

Thuja consists of the dried, leafy, young twigs of *Thuja occidentalis* Linné (Fam. *Pinaceæ*).

Thuja contains not more than 2 per cent of its stems over 4 mm. in diameter or other foreign organic matter. Only the recently dried drug should be used.

It contains a volatile oil, resin, tannin, *pinipicrin*, and *thujin*.

Description—Twigs, fan-shaped, flattened, bearing the scale-like leaves appressed in four rows; leaves of the edges boat-shaped, the intermediate flat, those at the tips of the twigs very broad, the lower elongated, all bearing conspicuous glands on the back. Odor strongly balsamic, aromatic and pungent; taste camphoraceous, terebinthinate and bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Thujæ.

Uses—A stimulant diuretic, and emmenagogue; dose thirty grains (2 Gm.)

Unofficial Substances Containing Volatile Oil and Resin

Alisma Water Plantain	From *Alisma plantago*—aquatica. Fam. *Alismaceæ*, indigenous to Europe. Contains an acrid resin
Oil of Water Plantain	A pungent oil
Cascarilla Sweet Bark (N. F. IV)	The dried bark of *Croton Eluteria* (Linné) Bennett (Fam. *Euphorbiaceæ*) without the presence of more than 5 per cent of adhering wood. It contains tannin, a bitter principle called *cascarillin*, resin, and about 1.6 per cent of volatile oil, greenish-yellow in color, of a sp. gr. of about 0.938. Aromatic and tonic in doses of 30 grains (2 Gm.)
Chenopodium American Wormseed	The fruit of *Chenopodium ambrosioides* Linné, and variety anthelminticum Gray (Fam. *Chenopodiaceæ*) and contains a volatile oil which is official, resin and a bitter principle. Used as an anthelmintic
Cunila Dittany	From *C. Mariana*, found in the United States. It contains volatile oil and resin
Juniperus Virginiana Red Cedar	The tops of *J. Virginiana*, grown in Canada and the United States. It contains volatile oil, resin, etc.
Oil of Red Cedar	Distilled from the wood of *Juniperus virginiana*

Unofficial Substances Containing Volatile Oil and Resin—*Continued*

Laserpitium White Gentian	From *L. latifolium*, found in Europe. It contains volatile oil and a bitter principle
Laurocerasus Cherry Laurel	From *Prunus laurocerasus*, found in Western Asia. It contains volatile oil, resin, etc.
Laurus Laurel	The leaves and fruit of *L. nobilis*, indigenous to the Levant. It contains volatile and fixed oils, also resin, etc.
Oil of Laurel	A pale yellow oxygenated oil, sp. gr. 0.91. The yield is about 2 per cent
Levisticum Lovage	From *L. officinale*, found in Europe. It contains volatile oil, resins, etc.
Liatris Liatris	From different species of *Liatris*, indigenous to North America
Myrtus Myrtle	From *M. communis*, found along the Mediterranean. It contains a volatile oil, resin, etc.
Ava-Kava	An intoxicating liquid, made from the root of *Piper methysticum*
Pimpernel Root (N. F. IV)	The dried rhizome and roots of *Pimpinella saxifraga* Linné, or *Pimpinella magna* Linné (Fam. *Umbelliferæ*). It contains resin and a volatile oil having a disagreeable odor and a bitter, acrid taste. Tonic, carminative, and diuretic effects. The dose is fifteen grains (1 Gm.)
Psoralea Psoralea	From different species of *Psoralea*, found in the United States. It contains a volatile oil and resin
Ptelea Shrubby Trefoil	From *P. Trifoliata*, found in North America. It contains a volatile oil and pungent resin
Ruta Graveolens Rue	The herb of *R. graveolens*
Oleum Rutæ Oil of Rue	A volatile oil from *Ruta graveolens*, sp. gr. 0.880, more soluble in water than most volatile oils. It is methyl-nonyl-ketone, $CH_3.CO.C_9H_{19}$
Sabina, Savin	The tops of *Juniperus sabina* Linné (Fam. *Coniferæ*). It contains a terpene, resin, and a trace of tannin. The dose is eight grains (0.5 Gm.)
Oleum Sabinæ, Oil of Savin	A volatile oil distilled from the fresh tops of savin. Used as a stimulant and emmenagogue and has frequently been used to produce abortion. It should never be sold except upon the order of a physician. Dose, one to five minims (0.06 to 0.03 cc.)
Wintera Winter's Bark	The bark of *Drimys Winteri*, grown in South America
Oil of Winter's Bark	The yield of volatile oil is about 1½ per cent.

CHAPTER LXIX

OFFICIAL DRUGS AND PRODUCTS CONTAINING VOLATILE OIL ASSOCIATED WITH BITTER PRINCIPLE OR EXTRACTIVE

ASPIDIUM. U.S. Aspidium

[Male Fern, Malefern Root, Male Shield Fern, Bear's Paw Root, Sweet Brake, Knotty Brake, Shield Root]

Aspidium consists of the rhizome and stipes of *Dryopteris Filix-mas* (Linné) Schott (Fam. *Polypodiaceæ*).

Aspidium yields not less than 6.5 per cent of oleoresin, and not more than 3 per cent of acid-insoluble ash. Only such portions as have retained their internal green color should be used.

Description—From 5 to 15 cm. long, 10 to 25 mm. in thickness, and, together with the closely imbricated, dark brown, roundish, and slightly curved stipe-remnants, 50 to 75 mm. in diameter, densely covered with brown, glossy, transparent, and soft, chaffy scales; internally pale green, rather spongy, vascular bundles about ten (*Dryopteris Filix-mas*) or six (*Dryopteris marginalis*) in number, arranged in an interrupted circle; odor slight, but disagreeable; taste sweetish, acrid, somewhat bitter, astringent, and nauseous.

For further description see the U. S. P. X.

U. S. P. Preparation—Oleoresina Aspidii.

Aspidium is said to contain the following constituents, in approximately the amount indicated: *filicic acid*, 3.5 per cent; *flavaspidic acid*, 2.5 per cent; *albaspidin*, 0.05 per cent; *aspidinol*, 0.10 per cent; *flavaspidin*, 0.10 per cent; *amorphous acid*, 5.0 per cent, and *filicic nigrine*, 60 per cent. These substances are, for the greater part, derivatives of phloroglucinol, and some of them are ketones possessing acid characters.

The various formulas assigned to the filicic acids and the different results reported regarding their physiologic activity have given rise to much confusion, leaving the chemistry in an unsettled condition. One of the first formulas assigned to filicic acid is that of Luck ($C_{26}H_{30}O_9$), which differs considerably from the formula $C_{14}H_{18}O_5$, given this substance by Grabowski, and $C_{14}H_{16}O_5$, as suggested by Dacoma. More recently, Gallas has stated the formula for both the crystalline and the amorphous filicic acid to be $C_{18}H_{22}O_6$.

The knowledge on the subject is very imperfect; but the majority of authors still accept filicic acid as one of the active constituents of aspidium.

In the case of oleoresin of aspidum any sediment which has separated consists of active constituents and should be incorporated before dispensing.

The oleoresin may be administered in the form of an emulsion made with the aid of acacia.

History—Male fern was first known to medicine in a patent medicine about 1770 called *Madame Nouffers cure for Tapeworm*. King Louis XVI of France gave the proprietress a sum equal to about $3500 for the secret, which was then given freely to the physicians of France. It had been mentioned as far back as the time of Dioscorides but had fallen into disuse for many centuries.

Uses—It is used as a tænifuge. Dose, one drachm (4 Gm.).

ERIODICTYON. U. S. Eriodictyon

[Eriodict.—Yerba Santa, Consumptives' Weed, Mountain Balm]

Eriodictyon is the dried leaf of *Eriodictyon californicum* (Hooker et Arnott) Bentham et Torrey (Fam. *Hydrophyllaceæ*).

Eriodictyon contains not more than 5 per cent of its stem or more than 2 per cent of other foreign organic matter.

Description—Oblong, lanceolate, 5 to 15 cm. long, acute at the apex, and below, narrowed into a short petiole, the margin sinuately toothed to nearly entire; upper surface green, smooth, and covered with a brownish resin; lower surface reticulate and minutely white-tomentose; odor somewhat aromatic; taste balsamic and sweetish.

For further description see the U. S. P. X.

U. S. P. Preparation—Fluidextractum Eriodictyi.

N. F. Preparations—Elixir Eriodictyi Aromaticum (from Fluidextract); Syrupus Eriodictyi Aromaticus (from Fluidextract).

Eriodictyon contains a bitter resin, volatile oil, and extractive. Its preparations are often used to disguise the taste of quinine.

Uses—It is given in doses of fifteen to sixty grains (1 to 4 Gm.) as a stimulating tonic.

MEZEREUM. N. F. Mezereum
(U. S. P. IX)

[Mezer.—Mezereon, Spurge Olive]

Mezereum is the dried bark from aerial portions of *Daphne Mezereum* Linné, *Daphne Gnidium* Linné, or of *Daphne Laureola* Linné (Fam. *Thymeleaceæ*).

Mezereum contains not more than 2 per cent of foreign organic matter.

Description—In long, thin bands, usually folded or rolled into disks; outer surface yellowish, brownish-yellow with transverse scars, and minute, blackish dots, underneath of a light greenish color; inner surface whitish, silky; bast in transverse layers, very tough; inodorous; taste very acrid.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Mezerei; Fluidextractum Sarsaparillæ Compositum; Linimentum Sinapis Compositum (from Fluidextract).

Uses—Mezereum contains *daphnin*, $C_{15}H_{16}O_9.2H_2O$, a glucoside, associated with an acrid soft resin and oil. Alcohol is the best menstruum for extracting the activity. Locally it is sometimes employed to stimulate sluggish ulcers. Mezereum is rarely given internally alone being usually combined with other drugs as an alterative, especially in the compound fluidextract of sarsaparilla. The dose is eight grains (0.5 Gm.).

PYRETHRUM. U. S. P. IX. Pyrethrum

[Pyreth.—Pellitory Root, Roman Pyrethrum, Pellitory]

The dried root of *Anacyclus Pyrethrum* (Linné) De Candolle (Fam. *Compositæ*). Preserve Pyrethrum in tightly closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects.

Official Description—Nearly cylindrical, slightly tapering, usually in pieces from 2.5 to 10 cm. in length and from 5 to 20 mm. in diameter; externally dark brown, deeply longitudinally furrowed and somewhat wrinkled, occasionally bearing short, tough, hair-like rootlets, crown more or less annulate, and occasionally tufted with coarse fibers or with long, soft-woolly, nearly straight, 1-celled hairs; fracture short; bark dark brown with 1 or 2 circular rows of resin ducts, closely adhering to the light yellow, radiate, porous wood, in the medullary rays of which occur 1 to 3 rows of resin ducts.

Odor and Taste—Odor distinct; taste sweetish, pungent, very acrid, tingling, and producing a strong sialogogue effect.

Tests for Identity and Purity—The powder is light to dark brown; when examined under the microscope it exhibits numerous spherical or irregular masses of inulin, the nature of which is especially seen with polarized light, and lignified fragments of the woody tissues and stone cells associated with cork; inulin in spherical granules or irregular masses, from 0.01 to 0.1 mm.

in diameter, which is not affected by the addition of iodine T.S.; tracheæ with simple pores and reticulate or scalariform thickenings, usually associated with wood parenchyma and with few or no wood fibers .stone cells in groups, the cells more or less tubular in outline and with thick, yellowish porous walls, cork in yellowish brown or dark brown fragments.

Pyrethrum yields not more than 5 per cent of ash.

Uses—A powerful irritant, employed as a sialogogue in certain forms of headache and neuralgic affections of the face, toothache, etc. Dose, 20 grains, (1.3 Gm.). The tincture was formerly official.

CIMICIFUGA. U.S. Cimicifuga

[**Cimicif.**—Black Cohosh, Black Snakeroot, Macrotys]

Cimicifuga consists of the dried rhizome and roots of *Cimicifuga racemosa* (Linné) Nuttall (Fam. *Ranunculaceæ*).

Cimicifuga contains not more than 2 per cent of its stems or other foreign organic matter, and yields not more than 4 per cent of acid-insoluble ash.

Description—The rhizome is of horizontal growth, hard, 5 cm. or more long, about 25 mm. thick, with numerous stout, upright or curved branches, terminated by a cup-shaped scar, and with numerous wiry-brittle, obtusely quadrangular roots, about 2 mm. thick; the whole brownish-black, of a slight but heavy odor, and a bitter, acrid taste.

For further description see the U. S. P. X.

The constituents are resin, an acrid principle (possibly an alkaloid), a resinous amorphous body, starch, tannin, gum, etc.

U. S. P. Preparation—Fluidextractum Cimicifugæ.

N. F. Preparations—Elixir Sodii Salicylatis Compositum (from Fluidextract); Elixir Tongæ et Salicylatum; Tinctura Cimicifugæ.

Uses—It is used as a sedative and alterative in chronic rheumatism and chorea. Dose, fifteen grains (1 Gm.).

APOCYNUM. N.F. Apocynum

[**Apocyn.**—Canadian Hemp]

Apocynum consists of the dried rhizome and roots of *Apocynum cannabinum* Linné (Fam. *Apocynaceæ*).

Apocynum contains not more than 5 per cent of its stems or other foreign organic matter.

Description—Cylindrical, somewhat branched, of varying length from 3 to 10 mm. in thickness; externally reddish-brown to grayish-brown, longitudinally wrinkled and occasionally with transverse fissures having vertical sides extending through the bark; fracture short; internally bark light brown, from 1.5 to 3 mm. in thickness, wood faintly radiate, and with large tracheæ, a small pith occurring in pieces of the rhizome. Almost inodorous; taste starchy, afterwards becoming bitter and somewhat acrid.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Apocyni.

Apocynum contains a volatile oil and a resin, but the chief constituents are *cynotoxin*, a crystalline substance, and the bitter glucosides, *apocynin*, *apocynein*, also bitter extractive, tannin, etc.

Uses—It is used in heart diseases and dropsies. Dose, five to twenty grains (0.3 to 1.3 Gm.).

Caution—It has been stated that the absorption of Apocynum in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient.

ARNICA. N.F. Arnica

(U. S. P. IX)

[**Arnic.**—Arnica Flowers, Leopardsbane]

Arnica is the dried flower head of *Arnica montana* Linné (Fam. *Compositæ*).

Arnica contains not more than 3 per cent of foreign organic matter. Arnica flowers contain a trace of volatile oil, and a bitter principle, *arnicin*, with resin, coloring matter, etc. Alcohol and water extract their virtues.

Description—Heads about 3 cm. broad, depressed-roundish, consisting of scaly involucre in two rows, bearing about sixteen yellow, strap-shaped, ten-nerved ray-florets, and numerous yellow, five-toothed, tubular disk-florets, having slender, spindle-shaped achenes, crowned by a hairy pappus. Odor feeble, aromatic; taste, bitter and acrid.
For a further description see the N. F. V.

N. F. Preparations—Fluidextractum Arnicæ; Tinctura Arnicæ.

Uses—It is rarely used internally, but the tincture is employed as an embrocation. Dose of the flowers fifteen grains (1 Gm.).

ASCLEPIAS. N. F. Asclepias

[**Asclep.**—Pleurisy Root, Butterfly Weed Root]

Asclepias is the dried roots of *Asclepias tuberosa* Linné (Fam. *Asclepiadaceæ*).
Asclepias contains not more than 5 per cent of foreign organic matter.

Description—Usually cut or broken pieces, of variable size, of an irregularly fusiform root which, when entire, is from 10 to 20 cm. in length and from 0.5 to 5 cm. in thickness; occasionally branched; externally pale orange-brown, becoming grayish-brown, annulate above, the surface roughened by numerous fine intersecting grooves; bark thin, fracture tough, the broken surface granular and white, with inconspicuous pale yellow wood bundles, and large white medullary rays. Odor slight; taste bitterish and disagreeable, somewhat acrid.
For further description see the N. F. V.

N. F. Preparation—Fluidextractum Asclepiadis.

It contains a principle *asclepiadin*, an amorphous lucoside, also *asclepin*, and a volatile oil.

Uses—It is used as a diaphoretic, emetic, and cathartic. Dose, thirty grains (2 Gm.).

CALENDULA. N. F. Calendula

[**Calend.**—Marigold, Hollygold, Marybud]

Calendula consists of the dried ligulate florets of *Calendula officinalis* Linné (Fam. *Compositæ*).
Calendula contains not more than 2 per cent of foreign organic matter.

Description—Florets from 15 to 25 mm. in length, yellow- or orange-colored, one- or three-toothed, four- or five-veined, margin nearly entire, the short hairy tube occasionally enclosing the remnants of a filiform style and bifid stigma. Odor slight, somewhat heavy; taste slightly bitter, faintly saline.
For further description see the N. F. V.

N. F. Preparations—Fluidextractum Calendulæ; Tinctura Calendulæ.

Calendula contains a small quantity of a volatile oil, a bitter principle, gum, sugar, etc. *Calendulin* is not the active principle, having very little taste.

Uses—Chiefly in domestic practice as a mild aromatic and diaphoretic. Dose, fifteen grains (1 Gm.).

CYPRIPEDIUM. N. F. Cypripedium

[**Cypriped.**—Ladyslipper Root]

Cypripedium consists of the dried rhizome and roots of *Cypripedium bulbosum* Miller, *Cypripedium pubescens* Willdenow, or of *Cypripedium parviflorum* Salisbury (Fam. *Orchidaceæ*).
Cypripedium contains not more than 3 per cent of other parts of the same plant or other foreign organic matter and yields not more than 6 per cent of acid-insoluble ash.

Description—Rhizome of horizontal growth, curved, from 3 to 10 cm. in length, and from 2 to 6 mm. in thickness, orange-brown to dark-brown, the upper side showing numerous circular, cup-shaped scars, closely covered below with simple wiry roots, varying from 3 to 15 cm. in length; fracture of rhizome, short, white, that of roots somewhat fibrous. Odor distinct, heavy; taste sweetish, bitter, and somewhat pungent.
For further description see the N. F. V.

N. F. Preparation—Fluidextractum Cypripedii.

This rhizome contains resins, an acid principle, volatile oil, tannin, starch, etc. Diluted alcohol extracts its virtues.

Uses—It is used as a nerve sedative. Dose, fifteen grains (1 Gm.).

DAMIANA. N. F. Damiana

[Turnera]

Damiana is the dried leaf of *Turnera diffusa* Willdenow ex. Schultes or of *Turnera Aphrodisiaca* Ward (Fam. *Turneraceæ*).

Damiana contains not more than 15 per cent of its stems, not more than 3 per cent of other foreign organic matter, and yields not more than 4 per cent of acid-insoluble ash.

It contains a volatile oil, an amorphous principle *damianin*, tannin, soft resin, etc.

Description—Obovate to lanceolate from 10 to 25 mm. in length and from 4 to 10 mm. in width, shortly petiolate, obtuse or acute at the apex, and with a short, cuneate base; sharply two- to ten-toothed on each side; the veins ascending, generally strong, straight and simple and running to the sinuses of the teeth, but sometimes branched and sending the branches into the teeth; the upper surface smooth and pale green, the lower glabrous or with a few hairs on the ribs (*Turnera aphrodisiaca*) or densely tomentose over the entire surface (*Turnera diffusa*). Intermixed with the leaves are frequently found some reddish twigs, the young tips and buds of which are grayish with appressed pubescence (*Turnera aphrodisiaca*) or white floccose (*Turnera diffusa*), also flower buds, yellowish flowers, and globose pods. Odor aromatic, taste characteristic, aromatic, and resinous.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Damianæ.

Uses—It has been recommended as an aphrodisiac. The dose is thirty grains (2 Gm.

EUPATORIUM. N. F. Eupatorium

[**Eupator.**—Thoroughwort, Boneset]

Eupatorium consists of the dried leaf and flowering tops of *Eupatorium perfoliatum* Linné (Fam. *Compositæ*).

Eupatorium contains not more than 10 per cent of its stems and not more than 2 per cent of foreign organic matter.

Description—Usually more or less broken; leaves opposite, the pair united at the base, from 8 to 20 cm. in length and from 1.5 to 5 cm. in breadth, tapering regularly from near the base to an acute summit, crenate-serrate, rugosely veined, rough and bright green above, yellowish-gray-green, tomentose, and resinous-dotted beneath; flower-heads small, numerous, corymbed, with a campanulate involucre of lance-linear, imbricated scales and with from ten to fifteen tubular, yellowish-white florets having a bristly pappus in a single row. Odor faintly aromatic; taste strongly bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Eupatorii.

This plant contains a volatile oil and resin, *eupatorin*, gum, tannin, sugar, etc. Alcohol, diluted alcohol, and water extract its virtues.

Uses—It is used as a diaphoretic and mild laxative. Dose, thirty grains (2 Gm.).

GRINDELIA. N. F. Grindelia

(U. S. P. IX)

[**Grindel.**—Grin Plant]

Grindelia consists of the dried leaves and flowering tops of *Grindelia camporum* Greene or *Grindelia cuneifolia* Nuttall, or *Grindelia squarrosa* (Pursh) Dunal (Fam. *Compositæ*).

Grindelia contains not more than 10 per cent of stems over 2 mm. in diameter, or more than 2 per cent of other foreign organic matter.

Description—Leaves about 5 cm. or less long, varying from broadly spatulate or oblong to lanceolate, sessile, or clasping, obtuse, more or less sharply serrate, often spinosely toothed, or even lacinate-pinnatifid, pale green, smooth, finely dotted, thickish, brittle; heads many-flowered, sub-globular or somewhat conical; the involucre hemispherical, about 10 mm. broad, composed of numerous imbricated, squarrosely-tipped or spreading scales; ray-florets yellow, ligulate, pistillate; disk-florets yellow, tubular, perfect; pappus consisting of two or three awns of the length of the disk-florets; odor balsamic; taste pungently aromatic and bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Grindeliæ.

Grindelia contains a volatile oil and a bitter and resinous principle.

Uses—A mild expectorant. The fluidextract is largely used in lotions mixed with water (1 to 10), for the treatment of ivy or rhus poisoning. Dose, thirty grains (2 Gm.).

INULA. N. F. Inula

[Elecampane, Horsehead]

Inula consists of the dried rhizome and roots of *Inula Helenium* Linné (Fam. *Compositæ*).

Inula contains not more than 5 per cent of its stem bases or other foreign organic matter.

It contains a volatile oil, a soft acrid resin, and a number of other constituents have been separated.

Description—Rhizome usually split into longitudinal or more or less oblique pieces to which may be attached one or more of the roots; up to 8 cm. in length and 4 cm. in diameter; externally grayish-brown to dark brown, longitudinally wrinkled with occasional buds or stem scars and surmounted at the crown by a portion of the over-ground stem; inner or cut surface somewhat concave, the edges incurved with the over-lapping bark; yellowish-brown to grayish-brown, longitudinally striate and more or less fibrous near the cambium zone; fracture short and horny; inner surface light brown and marked by numerous circular or elliptical oleoresinous canals; roots cylindrical and tapering, frequently curved or irregularly curled; up to 13 cm. in length and 1.5 cm. in diameter. Odor aromatic; taste acrid, bitter and pungent.

For further description see the N. F. V.

N. F. Preparations—Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe.

Uses—Inula was formerly employed in amenorrhea, diphtheria, and tuberculosis but is probably of no value. Dose, ten to thirty grains (0.6 to 2 Gm.). Externally it has been used as a rubefacient.

IRIS VERSICOLOR. N. F. Blue Flag

[**Iris Vers.**—Fleur de Lys]

Blue Flag is the dried rhizome of *Iris versicolor* Linné or of *Iris Caroliniana* Watson (Fam. *Iridaceæ*).

Blue Flag contains not more than 5 per cent of its roots and leaf bases or other foreign organic matter.

It contains volatile oil, an acrid resin, tannin, and possibly an alkaloid.

Description—Rhizome frequently branched, up to 10 cm. in length and 2 cm. in thickness, usually cut into longitudinal pieces; outer surface grayish-brown to purplish-brown, somewhat annulate, the upper surface with markings of leaf bases, the lower with numerous root scars and remnants; fracture short, the broken surface pale purplish-brown and exhibiting a central stele with whitish fibro-vascular bundles distributed throughout, a distinct endodermis and cortex. Odor slight, not distinctive; taste acrid, nauseous.

For further description see the N. F. V.

N. F. Preparations—Elixir Corydalis Compositum (from Fluidextract); Fluidextractum Iridis Versicoloris; Fluidextractum Stillingiæ Compositum; Syrupus Stillingiæ Compositum (from Compound Fluidextract).

Uses—It is used as an emetic and cathartic, sometimes used as a hepatic stimulant.

MATRICARIA. N. F. Matricaria

(U. S. P. IX)

[**Matricar.**—German Chamomile, Wild Chamomile]

Matricaria is the dried flower-head of *Matricaria Chamomilla* Linné (Fam. *Compositæ*).

Matricaria contains not more than 5 per cent of stems or foreign organic matter and yields not more than 4 per cent of acid-insoluble ash.

Description—About 15 to 20 mm. broad, composed of a flattish, imbricate involucre, a conical, hollow, naked receptacle, which is about 5 mm. high, about fifteen, white, ligulate, reflexed ray-florets, and numerous yellow, tubular, perfect disk-florets without pappus; strongly aromatic and bitter.

The similar flower-heads of *Anthemis arvensis* Linné and *Maruta Cotula* De Candolle (Fam. *Compositæ*) have conical, solid, and chaffy receptacles.

For further description see the N. F. V.

N. F. Preparation—Species Emollientes.

Matricaria contains a dark blue volatile oil, which is soluble in alcohol; the bitter-principle is termed *anthemic acid*.

Uses—It is used chiefly in domestic practice as a mild aromatic and diaphoretic. Dose, four drachms (15 Gm.).

PULSATILLA. N. F. Pulsatilla

[Pulsatil.—Pasque Flower, Wind Flower, Prairie Anemone]

Pulsatilla is the dried herb of *Pulsatilla vulgaris* (Linné) Miller, *Anemone pratensis* (Linné) Miller, or *Pulsatilla patens* (Linné) Miller (Fam. *Ranunculaceæ*).

Pulsatilla contains not more than 5 per cent of foreign organic matter.

It contains tannin, and an acrid volatile oil of which the chief constituent is a camphor which is quickly decomposed, in the presence of water, into *anemonin*, $C_{10}H_8O_4$, and *isoanemonic acid*, $C_{15}H_{14}O_7$. These are both crystalline.

Description—Leaves and flowering scapes matted, silky-villous; basal leaves with petioles up to 30 cm. in length, the latter hollow, often purplish in color, the blades twice or thrice deeply three- or four-parted or pinnately cleft, the lobes linear and acute, the base of the petiole more hairy than above and frequently attached to the short root-stock; flowering scapes up to 30 cm. in length, solid in the lower portion and hollow in the upper part, with sessile, involucral dissected leaves near the flower, occasionally with remains of the dull purple hairy sepals and the dense-woolly, plumose-tailed achenes. Nearly odorless; taste very acrid.

For further description see the N. F. V.

N. F. Preparation—Tinctura Pulsatillæ.

Uses—It has been used in ovarian and uterine diseases. In overdose it is an active irritant causing vomiting and purging. It is said to be a diuretic, diaphoretic, expectorant, and sedative. Dose, five grains (0.3 Gm).

SABAL. N. F. Sabal

(U. S. P. IX)

[Saw Palmetto Berries]

Sabal is the partially dried, ripe fruit of *Serenoa serrulata* (Michaux) Hooker filius (Fam. *Palmæ*).

Sabal contains not more than 1 per cent of foreign organic matter. Sabal should contain from 10 to 15 per cent of its natural moisture when used for the manufacture of pharmaceutical preparations.

Sabal contains a volatile oil, fixed oil, resin, and an alkaloidal principle.

Description—Ellipsoidal or ovoid, occasionally compressed, from 1.5 to 3. cm. in length and from 1 to 1.5 cm. in diameter; externally brownish-black to bluish-black, smooth and somewhat oily, with a few large, more or less angular depressions due to the contraction of the inner layer on drying, summit marked by a scar of the style, and the base either with a short stalk or stem-scar; epicarp and sarcocarp together forming a thin coriaceous shell enclosing a hard but thin endocarp, which is externally reddish-brown and somewhat fibrous, as is also the inner layer of the sarcocarp; inner layer of endocarp smooth, enclosing a hard, ellipsoidal or ovoid, somewhat flattened, reddish-brown seed. Odor pronounced, aromatic; taste sweetish, aromatic, slightly acrid.

For further description see the N. F. V.

N. F. Preparations—Elixir Sabal et Santali; Fluidextractum Sabal; Tinctura Sabal et Santali.

Uses—It is used in genito-urinary diseases. Dose, fifteen to thirty grains (1 to 2 Gm.).

SENECIO. N. F. Senecio

[Life Root Plant, Golden Ragroot]

Senecio is the dried plant of *Senecio aureus* Linné (Fam. *Compositæ*).

Senecio contains not more than 10 per cent of foreign organic matter.

It contains a volatile oil, and a small amount of a bitter principle. The constituents have not been thoroughly investigated.

Description—Stems from 3 to 6 dm. in length, if entire bearing a basal rosette of leaves; sparingly clothed with successively smaller leaves and bearing at the summit several yellow heads in a loose corymb, white floccose when young, but mostly glabrous when expanded, radical leaves on long, slender petioles, mostly of rounded form from 5 to 7 cm. in breadth, the base often cordate, the summit rounded, the margin crenate-dentate; stem-leaves gradually changing from the shape of the radical leaves to lyrately-pinnate, then pinnatified and sessile, and at length clasping, oblong and incised; heads slender peduncled, from 12 to 25 mm. in breadth, the lance-linear involucral scales in about two series, closely appressed, rays about ten, bright-yellow, disk flowers very numerous, small, bearing a glabrous akene and a white pappus. Odor characteristically aromatic; taste bitter, slightly astringent and distinctly acrid, and pungent.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Senecionis.

Uses—It is used as an emmenagogue; dose, one drachm (4 Gm.).

STILLINGIA. N. F. Stillingia

(U. S. P. IX)

[**Stilling.**—Queen's Root, Queen's Delight]

Stillingia is the dried root of *Stillingia sylvatica* Linné (Fam. *Euphorbiaceæ*).

Stillingia contains not more than 3 per cent of foreign organic matter. Stillingia which has been stored for more than two years must not be used.

Description—About 30 cm. long, and nearly 5 cm. thick, subcylindrical, slightly branched, compact, wrinkled, tough, grayish-brown, breaking with a fibrous fracture, showing a thick bark and porous wood, the inner bark and medullary rays having numerous yellowish-brown resin-cells; odor peculiar, unpleasant; taste bitter, acrid, and pungent.

For further description see the N. F. V.

N. F. Preparations—Elixir Corydalis Compositum (from Fluidextract); Fluidextractum Stillingiæ; Fluidextractum Stillingiæ Compositum; Fluidextractum Trifolii Compositum.

Stillingia contains an acrid resin called *sylvacrol*, starch, a volatile oil, a fixed oil, etc.

Uses—It is used as an alterative, in doses of thirty grains (2 Gm.).

VIBURNUM OPULUS. N. F. Viburnum Opulus

[**Viburn. Op.**—High Bush Cranberry Bark, Cramp Bark]

Viburnum opulus is the dried bark of *Viburnum Opulus* Linné var. *americanum* (Miller) Aiton (Fam. *Caprifoliaceæ*).

Viburnum Opulus contains not more than 5 per cent of adhering wood or other foreign organic matter.

Its constituents are similar to those found in *Viburnum Prunifolium*. This bark is similar in appearance to the *mountain maple* (*Acer spicatum* Lam.) and for many years this bark was substituted for it.

Description—In strips, or occasionally in quills or chip-like fragments, the bark attaining a thickness of 3 mm.; outer surface of the thinner pieces of a light gray color with crooked, longitudinal, purplish-brown stripes and very small brown lenticels, the thicker pieces purplish-red or occasionally blackish, except when very young and more or less finely fissured or thinly scaly; inner surface varying in color from yellowish to rusty-brown, with very short oblique striæ, except where the outer wood layer adheres; fracture short and weak, the fractured surface mostly whitish, varying to pale brown in the inner layer, rusty brown in the outer layer, covering the green tangential layers of phelloderm. Odor strong and characteristic; taste mildly astringent and decidedly bitter.

For further description see the N. F. V.

N. F. Preparation—Elixir Viburni Opuli Compositum (from Fluidextract); Tinctura Viburni Opuli Composita.

Uses—It is used as an antispasmodic and in the treatment of dysmenorrhea. The dose is twenty to sixty grains (1.3 to 4 Gm.).

VIBURNUM PRUNIFOLIUM. N. F. Viburnum Prunifolium

(U. S. P. IX)

[**Viburn. Prun.**—Black Haw, Viburnum]

Viburnum Prunifolium is the dried root bark of *Viburnum prunifolium* Linné (Fam. *Caprifoliaceæ*).

Virburnum Prunifolium contains not more than 7 per cent of wood or other foreign organic matter and yields not more than 3 per cent of acid-insoluble ash.

Description—In irregular, transversely curved or quilled pieces, from 1.5 to 6 cm. in length and from 0.5 to 1.5 mm. in thickness; outer surface grayish-brown, or, where the outer cork has scaled off, brownish-red, longitudinally wrinkled; inner surface reddish-brown, longitudinally striated; fracture short but uneven, showing in bark which is young or of medium thickness, a dark brown cork, a brownish-red outer cortex, and a whitish inner cortex in which are numerous light yellow groups of sclerenchymatous tissues.

Odor and Taste—Odor slight; taste distinctly bitter and somewhat astringent.

For further description see the N. F. V.

N. F. Preparations—Elixir Viburni Prunifolii (from Fluidextract); Fluidextractum Viburni Prunifolii.

Viburnum contains valeric acid, a bitter, resinous principle, *viburnin*, tannin, etc. Alcohol is the best solvent for its active principles.

Uses—It is used in menstrual disorders. Dose, thirty grains (2 Gm.).

TRILLIUM. N. F. Trillium

[Trill.—Beth Root, Wake Robin]

Trillium consists of the dried rhizome of *Trillium erectum* Linné and other species of *Trillium* (Fam. *Liliaceæ*).

Trillium contains not more than 2 per cent of foreign organic matter. It contains a small amount of volatile oil, tannin, and a principle similar to saponin.

Description—Rhizome oblique, globular, oblong or obconical, truncate below, terminated by a small bud surrounded by a sheath of scarious leaf bases, annulated by leaf scars and fissured by stem scars; from 0.6 to 5 cm. in length and from 0.6 to 2.5 cm. in width, more or less compressed laterally, rootlet scars in several concentric rows on the under side in the upper portions; externally yellowish to reddish-brown; internally of a pale yellow; fracture somewhat uneven with a more or less spongy appearance. Odor distinct; taste bitter and acrid with a sensation of warmth in the throat, and when chewed causing an increased flow of saliva.

For further description see the N. F. V.

N. F. Preparations—Elixir Viburni Opuli Compositum (from Fluidextract); Fluidextractum Trillii.

Uses—It is used as an emmenagogue. Dose, thirty grains (2 Gm.).

XANTHOXYLUM. N. F. Xanthoxylum

(U. S. P. IX)

[Xanthox.—Prickly Ash Bark, Pepperwood, Toothache Tree]

Xanthoxylum is the dried bark of *Xanthoxylum americanum* Miller, known in commerce as Northern Prickly Ash Bark, or *Xanthoxylum Clava-Herculis* Linné, known in commerce as Southern Prickly Ash Bark (Fam. *Rutaceæ*).

Xanthoxylum contains not more than 2 per cent of foreign matter.

Description—*Xanthoxylum americanum* (Northern Prickly Ash) is in curved or quilled fragments, about 1 mm. thick; outer surface brownish-gray, with whitish patches, and minute, black dots, faintly furrowed, with some brown, glossy, straight, two-edged spines, linear at the base, and about 5 mm. long; inner surface whitish, smooth; fracture short, non-fibrous, green in the outer and yellowish in the inner layer; inodorous; taste bitterish, very pungent.

Xanthoxylum Clava-Herculis (Southern Prickly Ash) resembles the preceding, but is about 2 mm. thick, and is marked by many conical, corky projections, sometimes 2 cm. high, and by stout, brown spines, rising from a corky base.

Xanthoxylum should not be confounded with the bark of *aralia spinosa* Linné (Fam. *Araliaceæ*), which is nearly smooth externally, and beset with slender prickles in transverse rows.

For further description see the N. F. V.

N. F. Preparations—Elixir Corydalis Compositum (from Fluidextract); Fluidextractum Trifolii Compositum; Fluidextractum Xanthoxyli.

Xanthoxylum owes its virtues to a soft resin, a crystalline resin, a bitter principle, and an acrid green oil. There are also present sugar, tannin, gum, etc.

Uses—It is used as an alterative. Dose, thirty grains (2 Gm.).

XANTHOXYLI FRUCTUS. N. F. Prickly Ash Berrys

[Xanthox. Fruct.]

Prickly Ash Berrys are the dried fully grown fruit of *Xanthoxylum americanum* Miller (Northern Prickly Ash) or *Xanthoxylum Clava-Herculis* Linné (Southern Prickly Ash) (Fam. *Rutaceæ*).

Prickly Ash Berrys contain not more than 2.5 per cent of foreign organic matter. The constituents are similar to those found in the bark (see above).

Official Description—Capsules with short stalks (*X. americanum*) or without stalk (*X. Clava-Herculis*); when fresh, ellipsoidal, fleshy, gray-brown, when dry, dehiscent; carpels two, convex, summit short pointed; seeds one or two, oblong, black, shining, and wrinkled from drying. The carpels have a pungent, warm, aromatic taste and on chewing leave a tingling sensation on the tongue; when breathed upon they emit a faintly aromatic odor resembling that of citral.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Stillingiæ Compositum; Syrupus Stillingiæ Compositus (from Compound Fluidextract).

Uses—It is supposed to possess alterative virtues. Dose, fifteen grains (1 Gm.).

ZEA. N. F. Zea

[Corn Silk]

Zea consists of the fresh styles and stigmas of *Zea Mays* Linné (Fam. *Gramineæ*). Zea should be collected when the ears are in milk and used in the green condition for the manufacture of pharmaceutical preparations.

It contains a small amount of volatile oil, also a fixed oil, resin, and *maizenic acid*, with sugar and gum.

Description—In slender filaments from 10 to 20 cm. in length, and about 0.4 mm. in diameter; of a light green, purplish-red, yellow or light brown color; stigmas bifid, the segments very slender, frequently unequal and from 0.4 to 3 mm. in length.

Under the microscope, the styles are seen to consist for the most part of parenchyma and two parallel, vascular bundles with narrow, spiral or annular tracheæ; the epidermal cells are rectangular, many of these being extended into multicellular hairs, the latter being from 0.2 to 0.8 mm. in length, the basal portion consisting of two to five united cells, the upper portions being usually unicellular; the cells of the hairs are rich in cytoplasm and usually contain a small, spherical nucleus; the purplish-red styles contain a purplish-red cell cap.

N. F. Preparations—Elixir Sabal et Santali compositum; Fluidextractum Zeæ.

Uses—It is used in inflammation of the bladder. Preparations of the fresh drug are more active than those made from the dry drug, as the volatile principles are retained. Dose, one to two drachms (4 to 8 Gm.).

Unofficial Volatile Oils and Drugs Containing Volatile Oil, Bitter Principle, or Extractive

Absinthium Wormwood (N. F. IV)	The dried leaves and flowering tops of *Artemisia Absinthium* Linné (Fam. *Compositæ*). It contains 1 per cent or more of a volatile oil, bitter and disagreeable in taste, containing *thujone*, $C_{10}H_{16}O$, phellandrene, and small amounts of other constituents. The drug also contains a glucoside, *absinthin*, $C_{15}H_{20}O_4$. Formerly used as an anthelmintic. A narcotic poison in overdoses. Dose, thirty grains (2 Gm.)
Achillea Yarrow	A perennial herb of the Family *Compositæ*, *Achillea millefolium*, growing in America and Europe. It contains *achilleine*
Oleum Achilleæ Oil of Yarrow	A blue or dark green volatile oil. The yield is about $\frac{1}{10}$ per cent.
Anthemis (U. S. P. VIII)	The dried flower heads of *Anthemis nobilis* Linné (Fam. *Compositæ*), collected from cultivated plants. It contains a volatile oil and a bitter principle called *anthemic acid*. It is used as a tonic. Dose, thirty grains (2 Gm.)
Arnicæ Radix Arnica Root (U. S. P. 1890)	The rhizome and roots of *Arnica montana* Linné (Fam. *Compositæ*). It contains 1 per cent of volatile oil, a bitter principle *arnicin*, acrid resin, etc.
Angustura Angustura Bark	The bark of *Galipea cusparia*, from the mountains near the Orinoco River
Oil of Angustura, $C_{13}H_{24}O$	The yield of oil is about $\frac{1}{2}$ per cent.
Apocynum Androsæmifolium Dogsbane	A root which grows in New England and Canada
Artemisia Mugwort	From *Artemisia vulgaris*. It contains volatile oil, bitter principle, etc.
Bela Bael	From *Ægle marmelos*, grown in the Himalaya Mountains. It contains tannin, bitter principle, and volatile oil
Carthamus American Saffron, Safflower	See the chapter on coloring, page 845
Chekan Cheken	The leaves of *Eugenia chekan*, grown in Chili. It contains volatile oil, bitter principle, chekenon, chekenin, chekenetin, and cheken-bitter. Dose of the fluidextract, one to three fluidrachms (4 to 12 cc.)
Clematis Virgin's Bower	The herb from different species of *Clematis*
Erigeron Erigeron	The leaves and tops of *Erigeron canadensis*. Diuretic, tonic, astringent. Dose, in substance, one drachm (4 Gm.)
Oil of Erigeron (Oil of Fleabane) (U. S. P. VIII)	From the fresh flowering herb *Erigeron canadensis* Linné (Fam. *Compositæ*). It consists chiefly of *d-limonene* and it also contains an oxygenated portion. Used as an hæmostatic in uterine hemorrhage in a fifteen minim (1 cc.) dose
Euphrasia Eyebright	*Euphrasia officinalis*, indigenous to Europe
Genista Dyers' Broom	The young branches of *Genista tinctoria*, indigenous to Asia and Europe. It contains a yellowish-green volatile oil
Geum Water Avens	The rhizome of *Geum rivale*, grown in America and Europe. It contains volatile oil and bitter principle
Gnaphalium Life-Everlasting	From different species of *Gnaphalium*, grown in North America. It contains volatile oil and bitter principle
Helianthemum Frost Weed Rock-rose	The dried herb of *Helianthemum canadense* (Linné) Michaux (Fam. *Cistaceæ*). It contains a volatile oil, a fixed oil, tannin, and an alkaloidal principle. Dose, one drachm (4 Gm.). It is supposed to possess alterative properties
Hypericum St. John's-wort	From *Hypericum perforatum*, grown in Europe. It contains hypericum red, volatile oil, etc.

Unofficial Volatile Oils and Drugs Containing Volatile Oil, Bitter Principle, or Extractive—*Continued*

Lactucarium (U. S. P. IX)	The dried milk-juice of *Lactuca virosa* (Fam. *Compositæ*). Lactucarium is a complex substance. It contains a bitter resinous principle, *lactucin*, $C_{11}H_{12}O_3$ H_2O, *lactucic acid* (bitter and crystalline), *lactucopicrin* (bitter and amorphous), *lactucerin* or *lactucon* in large quantity, nearly 60 per cent (this principle is inert and crystallizable), caoutchouc, resin, asparagin, volatile oil, mucilage, etc. It is used as a sedative but has little if any action aside from its paste. Contrary to the popular opinion it bears no relationship to opium and contains no narcotic principle of importance or value. Dose, fifteen grains (1 Gm.)
Paracoto (N. F. IV)	The dried bark of an unidentified tree indigenous to Northern Bolivia. It contains a volatile oil, a volatile alkaloid, *propylamine*, *phenylcoumarin*, *piperonylic acid* and *cotoin*, $C_{14}H_{12}O_4$. Cotoin is obtained by extraction with ether and purified. *Dicotoin* is an impure mixture. An intestinal stimulant used in diarrhea. Dose, five grains (0.32 Gm.)
Parthenium Feverfew	The flowering herb of *Pyrethrum parthenium*, growing in waste places in Europe. It contains volatile oil and bitter principle
Phytolaccæ Fructus Poke Berries (U. S. P. 1890)	The fruit of *Phytolacca decandra* Linné (Fam. *Phytolaccaceæ*). It contains coloring matter, sugar, gum, etc. Used as an alterative
Primula Primrose	From *Primula officinalis*, indigenous to Europe and Asia. It contains a volatile oil and primulin
Pyrethrum Pellitory Root (U. S. P. IX)	The dried root of *Anacyclus* (Linné) De Candolle (Fam. *Compositæ*). This root contains an acrid, brown resin, containing *pelletorin*, the alkaloid *pyrethrine*, and a volatile and a fixed oil, inulin, mucilage, etc. It is used as a sialagogue and stimulant, in doses of fifteen to forty grains (1 to 2.6 Gm.)
Ranunculus Crowfoot	From *Ranunculus bulbosus*, found in North America. It contains a golden yellow volatile oil and a bitter principle
Tanacetum Tansy (U. S. P. 1890)	The leaves and tops of *Tanacetum vulgare* Linné (Fam. *Compositæ*). The bitter principle is *tanacetin*
Teucrium Germander	From *Teucrium Marum*, indigenous to Europe. It contains volatile oil and bitter principle
Tilia Linden Flowers	From *Tilia americana*. It contains volatile oil, bitter principle, etc.

CHAPTER LXX

RESINS, OLEORESINS, GUM RESINS, AND BALSAMS

Resins are natural or induced solid or semi-solid exudations from plants, characterized by being insoluble in water, mostly soluble in alcohol or ether, often uncrystallizable, and softening or melting at a moderate heat. They are usually the *oxidized terpenes* of the volatile oils of plants, and, owing to their insolubility in water, have little taste; they show no uniformity of chemical composition; some of them are acids, and combine with alkalies, forming soaps, as in the case of common rosin.

Resins, when pure, are usually transparent; when they contain water, they are opaque, and no longer hard and brittle.

A clear distinction must be made between natural resins and prepared resins. A natural resin is one which occurs as an exudation. Of this class Mastic is an official example; being in the N. F. A prepared resin may be made by exhausting a drug, which owes its activity to resinous constituents, with alcohol, pouring the concentrated alcoholic percolate into an excess of water, collecting, washing and drying the precipitate. The resins of podophyllum, jalap, etc. (see Resinæ, Part III), are examples of this class. A prepared resin may also be derived from a natural oleoresin by driving off the volatile oil by heat. Resina is an example of this class.

Natural oleoresins are mixtures of volatile oils and resin, generally obtained by incising the trunks of the trees in which they are found, as turpentine, copaiba, etc.

A distinction must be made also between the natural and prepared oleoresins. The prepared oleoresins are a class of powerful liquid preparations made by percolating drugs, naturally containing both volatile oil and resin, with an appropriate solvent, *i.e.*, acetone, ether or alcohol, and concentrating the percolate until the solvent has been dissipated. Examples of oleoresin are aspidium, capsicum, etc., see Oleoresinæ, Part III.

Gum resins are natural mixtures of gum and resin, usually obtained as exudations from plants, as myrrh, asafetida, etc.

Balsams are resinous substances which contain benzoic, or cinnamic acids or their esters, as balsam of tolu, balsam of Peru, etc.

Much faulty nomenclature occurs in the ordinary trade designations for many of these drugs. The word "*gum*" is frequently the one most misapplied as in *gum thus* for oleoresin of turpentine, *gum guaiac* for resin of Guaiac, *gum asafetida* for gum resin of asafetida (see also Gums, page 885). The word *balsam* is also wrongly applied to certain oleoresins as copaiba and Canada turpentine, neither of which contains any of the constituents characteristic of balsams.

The official resins, oleoresins, gum resins, and balsams will now be considered.

OLEUM TEREBINTHINÆ. U. S. Oil of Turpentine

[Ol. Tereb.—Turpentine Oil, "Spirits of Turpentine"]

The volatile oil distilled from the oleoresin obtained from *Pinus palustris*, Miller and other species of *Pinus* (Fam. *Pinaceæ*) which yield exclusively terpene oils.

This important oil has the composition $C_{10}H_{16}$, and, as has been already stated, is the type of the terpenes. It is used as a solvent in pharmacy.

Description and Physical Properties—A colorless liquid, having a characteristic odor and taste, both of which become stronger and less pleasant on aging or exposure to air.

Tests for Identity and Purity—The Oil is soluble in 5 volumes of alcohol.

Specific gravity: 0.854 to 0.868 at 25° C.

Optical rotation: active, but variable, page 1524.

Refractive index: 1.4680 to 1.4780 at 20° C., page 1525.

An alcoholic solution of the recently distilled Oil (1 in 5) is neutral or only slightly acid to moistened litmus paper.

Evaporate 5 cc. of the Oil in a small tared dish on a bath of boiling water: the weight of the residue does not exceed 0.1 Gm. (*petroleum, paraffin, or rosin oils*).

Three drops of the Oil placed on white unsized paper and exposed to the air, evaporate without leaving a permanent stain (*fixed oils*).

A 5 cc. portion of the Oil shaken with an equal volume of potassium hydroxide T.S. does not become darker than a light straw-yellow after standing twenty-four hours.

A 5 cc. portion of the Oil shaken vigorously with an equal volume of hydrochloric acid in a glass-stoppered cylinder and allowed to stand for five minutes does not develop a color darker than a light straw yellow in either the acid or the oil layer.

Place 100 cc. of Oil of Turpentine in a standard 100 cc. Engler flask, having the side tube 8 cm. above the top of the bulb, and distil the Oil at the rate of 2 drops per second: 90 per cent of the Oil distils between 154° and 170° C., the temperature being read with the bulb of the thermometer opposite the side tube of the flask, and the top of the mercury column of the thermometer remaining within the neck of the flask.

Place 20 cc. of fuming sulphuric acid (page 1543) in a graduated narrow-necked Babcock bottle, stopper, and place in an ice bath to cool, and then add slowly, drop by drop, from a pipette, 5 cc. of the Oil of Turpentine. Mix the acid and Oil, as added, by gently shaking or rotating the bottle, keeping the temperature at about 60° to 65° C. by continued immersion in the ice bath. When the mixture no longer becomes warm on shaking, agitate thoroughly by vigorously shaking for about one-half minute. Place the bottle in a water bath and heat at 60° to 65° C. for ten minutes, keeping the contents of the bottle thoroughly mixed by frequent vigorous shaking, not less than six times during the heating period.

(*If the shaking at first is too prolonged and vigorous, there is danger of the escaping SO_2 forcing some of the mixture out of the neck of the bottle.*)

Cool to room temperature and fill the bottle with sulphuric acid (specific gravity about 1.83) until the oily layer rises into the graduated neck. Centrifuge for five minutes at 1200 revolutions per minute, or for fifteen minutes at 900 revolutions per minute, or allow to stand, lightly-stoppered, for twelve hours. The reddish or straw-colored viscous layer which separates on top of the dark acid does not exceed 1 per cent (0.05 cc.) of the volume of Oil taken (*mineral oil*).

Caution—The addition of Oil of Turpentine to the fuming sulphuric acid, must be made only drop by drop because of the violence of the reaction.

Preserve in well-stoppered containers, in a cool place.

U. S. P. Preparations—Ceratum Cantharidis; Oleum Terebinthinæ Rectificatum.

N. F. Preparations—Linimentum Opii Compositum; Linimentum Terebinthinæ; Linimentum Terebinthinæ Aceticum; Petroxolinum Sulphuratum Compositum.

Uses—Paint store "turpentine" or "turps" frequently consists of a mixture of turpentine and a petroleum distillate. Wood turpentine made by distilling old stumps, etc., with steam, also constitutes much of the cheap turpentine of the market. This variety although closely resembling genuine oil of turpentine in its physical properties, is considered unsuitable for medicinal use.

Oil of turpentine when old becomes ozonized and produces a characteristic bleaching action upon the cork stopper of the bottle containing it. Upon long exposure it ultimately thickens and partly resinifies by oxidation.

Oil of turpentine is applied externally in liniments as a stimulant and counterirritant. The rectified oil of turpentine should be used internally.

OLEUM TEREBINTHINÆ RECTIFICATUM. U.S. Rectified Oil of Turpentine

[Ol. Tereb. Rect.—Rectified Turpentine Oil]

Oil of Turpentine, a convenient quantity.
Solution of Sodium Hydroxide, an equal quantity.

Mix the two liquids thoroughly in a suitable still provided with a well-cooled condenser. Recover about three-fourths of the Oil by distillation, and

separate the clear oil from the water. Dry the Oil by shaking with anhydrous calcium chloride or anhydrous sodium sulphate, and filter.

NOTE—Rectified Oil of Turpentine is to be dispensed when Oil of Turpentine is required for internal use. Oil that has become turbid should not be dispensed.

Description and Physical Properties—A colorless liquid which conforms to the properties and tests under *Oleum Terebinthinæ*, specific gravity and non-volatile residue excepted.

Specific gravity: 0.853 to 0.862 at 25° C.

Evaporate 5 cc. of Rectified Oil of Turpentine rapidly in a tared dish on a bath of boiling water: the weight of the residue does not exceed 0.015 Gm.

Preserve in well-stoppered, amber-colored bottles in a cool place, protected from light.

U. S. P. Preparation—Emulsum Olei Terebinthinæ.

Uses—It is used as a stimulant diuretic, carminative, and expectorant and may be given in the dose of five minims (0.3 cc.). The purpose of this preparation is merely to provide a purer form of oil for internal use.

As this oil deteriorates upon keeping, by ozonizing and finally resinifying, it should not be kept on hand for too long a time before using.

TEREBENUM. U. S. Terebene

[Tereben.]

Terebene is a mixture of terpene hydrocarbons, chiefly dipentene and terpene, obtained from oil of turpentine.

Description and Physical Properties—A colorless, thin liquid. It has a rather agreeable, thyme-like odor, and a somewhat terebinthinate taste.

On exposure to light and air, Terebene gradually becomes resinified and acquires an acid reaction.

It is practically insoluble in water, but miscible with chloroform, ether, and dehydrated alcohol. One cc. is soluble in 3 cc. of alcohol at 25° C.

Tests for Identity and Purity—Specific gravity: 0.860 to 0.865 at 25° C.

It boils between 160° and 172° C.

Terebene does not redden blue litmus paper which has been moistened with alcohol.

Its optical rotation does not exceed + 0.3° in a 100 mm. tube at 25° C. (*unaltered oil of turpentine*).

After the determination of the boiling point, transfer the residue remaining in the distilling flask to a dish, by means of ether, and evaporate the liquid on a water bath; the residue remaining does not exceed 1 per cent of the original weight of Terebene taken (*rosin*).

Preserve in well-closed containers, protected from light.

Uses—Terebene is a valuable stimulating expectorant, given in capsules or in an emulsion in doses of four to sixty minims (0.25 to 4 cc.) during the day.

TERPINI HYDRAS. U. S. Terpin Hydrate

[Terpin. Hyd.]

A dihydric alcohol [$C_{10}H_{18}(OH)_2.H_2O$ = 190.23].

Terpin hydrate is made by acting on a mixture of oil of turpentine and alcohol with nitric acid; after standing three or four days the crystals which form are purified by recrystallization.

Description and Physical Properties—Colorless, lustrous crystals, or a white powder. It has a slight odor, and is efflorescent in dry air.

One Gm. of Terpin Hydrate is soluble in about 200 cc. of water, 13 cc. of alcohol, 135 cc. of chloroform, and in 140 cc. of ether, at 25° C. One Gm. is soluble in about 34 cc. of boiling water, in 3 cc. of boiling alcohol, and in about 1 cc. of boiling glacial acetic acid.

When slowly heated to about 100° C., Terpin Hydrate sublimes in fine needles. It loses its water of crystallization at 100° C. It is also slowly dehydrated by drying over sulphuric acid.

Tests for Identity—When quickly heated, Terpin Hydrate melts between 115° and 117° C. with the loss of water.

Add a few drops of sulphuric acid to a hot aqueous solution of Terpin Hydrate: the liquid becomes turbid and develops a strongly aromatic odor.

Test for Purity—Terpin Hydrate has no odor of turpentine and its hot aqueous solution (1 in 100) is not acid to litmus paper.
Ash: not more than 0.05 per cent.
Preserve in well-closed containers, in a cool place.

N. F. Preparations—Elixir Terpini Hydratis; Elixir Terpini Hydratis et Codeinæ; Elixir Terpini Hydratis et Creosoti Compositum.

Uses—Terpin hydrate is used in bronchitis, in doses of two to four grains (0.125 to 0.25 Gm.).

Its slight solubility in water leads to dispensing difficulties. If the solvent is deficient in alcohol the terpin hydrate crystallizes out, if too high in alcohol sugar will crystallize out if present.

RESINA. U. S. Rosin

[**Resin.**—Colophony, Georgia Pine Rosin, Yellow Pine Rosin]

The residue left after distilling the volatile oil from the oleoresin obtained from *Pinus palustris* Miller and from other species of *Pinus* (Fam. *Pinaceæ*).

Description and Physical Properties—Sharply angular, translucent, amber-colored fragments, frequently covered with a yellow dust, fracture brittle at ordinary temperature, shiny and shallow-conchoidal. The odor and taste are slightly terebinthinate.
Rosin is freely soluble in alcohol, ether, benzene, glacial acetic acid, and in fixed or volatile oils. It is also soluble in dilute solutions of the fixed alkali hydroxides.
Tests for Identity and Purity—Its alcoholic solution is acid to litmus paper.
Specific gravity: 1.07 to 1.09 at 25° C.
Rosin is easily fusible and burns with a dense yellowish smoke.
Ash: not more than 0.05 per cent.
Acid number: not less than 150, page 1512.

U. S. P. Preparations—Ceratum Cantharidis; Ceratum Resinæ.
N. F. Preparations—Ceratum Resinæ Compositum; Linimentum Terebinthinæ (from Rosin Cerate); Solutio Resinæ Chloroformica.

Uses—It is a component of plasters, cerates and ointments to which it adds adhesive qualities. Its principal industrial uses are in sizing, waterproofing, soap making, etc.

TEREBINTHINA. N. F. Turpentine

[**Terebinth**—Gum Thus]

Turpentine is a concrete oleoresin obtained from *Pinus palustris* Miller and from other species of *Pinus* (Fam. *Pinaceæ*).
Turpentine contains not more than 2 per cent of foreign matter.
White turpentine contains *abietic anhydride*, which may be converted into *abietic acid*, $C_{44}H_{64}O_5$, a bitter principle, and 25 per cent. of volatile oil.

Official Description—Turpentine occurs in yellowish, opaque masses, lighter internally, sticky and more or less glossy, brittle in the cold.
Odor, Taste, and Reaction—Odor and taste characteristic. Its alcoholic solution is acid to litmus.
Solubility—Freely soluble in alcohol, ether, chloroform, or glacial acetic acid.
For further description see the N. F. V.

N. F. Preparation—Ceratum Resinæ Compositum.

Uses—It is an ingredient in compound rosin cerate and in some unofficial plasters, and is sometimes administered in pill form. Dose, fifteen to thirty grains (1 to 2 Gm.).

OLEUM PINI PUMILIONIS. U. S. Oil of Dwarf Pine Needles

[**Ol. Pin. Pumil.**—Dwarf Pine Oil]

The volatile oil distilled from the fresh leaves of *Pinus montana* Miller (*Pinus Pumilio* Haenke) (Fam. *Pinaceæ*).

Oil of Dwarf Pine Needles yields not less than 5 per cent of esters, calculated as bornyl acetate [$C_{10}H_{17}.C_2H_3O_2$].

Description and Physical Properties—A colorless or faintly yellowish liquid, having a pleasant, aromatic odor, and a bitter, pungent taste.

Tests for Identity and Purity—The Oil is soluble in 10 volumes of 80 per cent alcohol, by volume.

Specific gravity: 0.853 to 0.869 at 25° C.

Optical rotation: varies from −4° 30′ to −9° in a 100 mm. tube at 25° C., page 1524.

Refractive index: 1.4750 to 1.4800 at 20° C., page 1525.

A solution of the recently distilled Oil in 80 per cent alcohol (1 in 10) is neutral or only slightly acid to moistened litmus paper.

Less than 1 per cent of the Oil distils below 165° C.

Assay—Proceed as directed for esters under *Oleum Menthæ Piperitæ*, page 1461, using 10 cc. of Oil of Dwarf Pine Needles. Multiply the number of cc. of half-normal alcoholic potassium hydroxide, consumed in the saponification, by 9.811, and divide the product by the weight of the Oil taken. The result shows the per cent of esters, calculated as bornyl acetate.

Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

This oil is obtained from the Tyrolese Alps and contains *l-pinene*, *l-phellandrene*, *sylvestrene*, *bornyl acetate*, and *cadinene*.

Uses—Used locally and internally in chronic rheumatic affections, but chiefly as an inhalant in bronchial affections.

ASAFŒTIDA. U.S. Asafetida

[**Asafœt.**—Gum Asafetida, Fetty]

Asafetida is the gum-resin obtained by incising the living rhizomes and roots of *Ferula Asafœtida* Linné and *Ferula fœtida* Regal and of other species of *Ferula* (Fam. *Umbelliferæ*).

Asafetida yields not less than 50 per cent of alcoholic-soluble extractive, and not more than 15 per cent of acid-insoluble ash.

Description and Physical Properties—A soft mass, sometimes almost semi-liquid, or irregular more or less pliable masses composed of agglutinated tears imbedded in a yellowish-brown or dark brown matrix, or loose ovoid tears from 1 to 4 cm. in diameter, the surface sometimes containing streaks of violet, yellowish-red or brownish-red and with a few vegetable fragments; becoming hard and occasionally brittle on drying; surface of the freshly fractured tears milky-white and opaque, changing gradually on exposure to air or light to a pinkish or reddish-purple or even reddish-brown; on moistening with water the tears become milky-white; odor persistent, alliaceous; taste bitter, alliaceous and acrid.

Tests for Identity—Asafetida, triturated with water, yields a milk-white emulsion, which becomes yellowish on the addition of alkalies.

A reddish-brown solution is formed when a fragment of Asafetida is heated with sulphuric acid. Greatly dilute this solution with water, filter, and render alkaline; the solution acquires a blue fluorescence.

A few drops of phloroglucinol T.S. and of hydrochloric acid, added to 10 cc. of the alcoholic filtrate obtained in the assay, produces a cherry-red color.

Tests for Purity—A few drops of ferric chloride T.S., added to 5 cc. of the alcoholic filtrate obtained in the assay, produces an olive-green color (*most foreign resins*). Hydrochloric acid, added to 10 cc. of the alcoholic filtrate from the assay until a faint turbidity results, produces a bluish-green color which fades on standing (*galbanum*).

Asafetida does not show the presence of rosin, page 1519.

Mix 2 cc. of an emulsion, prepared as directed under *Emulsum Asafœtidæ*, with 5 cc. of water and add 5 cc. of sodium hypobromite T.S. to form a separate layer: a red color is not produced (*ammoniac*).

Assay—Place about 10 Gm. of Asafetida in a tared, 250 cc. Erlenmeyer flask, weigh accurately, add 100 cc. of alcohol, and having connected the flask with an upright condenser, boil the mixture in the flask during one hour or until the drug is completely disintegrated. Filter and wash the flask and filter with several small portions of boiling alcohol until the washings no longer produce a cloudiness when dropped into water. Collect the mixed alcoholic solutions, using an aliquot part (50 per cent) for the completion of the assay, and reserve the remainder for the tests given above. Evaporate the aliquot part in a suitable tared container and dry to constant weight. The anhydrous alcohol-soluble extractive of the aliquot portion equals not less than 25 per cent of the weight of Asafetida taken.

U. S. P. Preparations—Emulsum Asafœtidæ; Pilulæ Asafœtidæ; Tinctura Asafœtidæ.

N. F. Preparations—Mistura Magnesiæ, Asafœtidæ et Opii (from Tincture); Pilulæ Aloes et Asafœtidæ.

A volatile oil is found in this gum resin, containing sulphides, also about 20 per cent of gum, and not less than 60 per cent of resin. The gum is partially

soluble in water; the resin is soluble in alcohol, and yields resorcinol by treatment with potassium hydroxide, and umbelliferone by dry distillation. The asafetida which reached this country was grossly adulterated until the regulations of the Food and Drugs Act were enforced. It may now be obtained of good quality. The valuable principles in asafetida are soluble in alcohol; with water an emulsion may be formed, which possesses its virtues.

Uses—It is used as an antispasmodic. Dose, six grains (0.4 Gm.).

MYRRHA. U.S. Myrrh

[**Myrrh.**—Gum Myrrh]

Myrrh is a gum resin obtained from *Commiphora Myrrha* (Nees) Baillon or from other species of *Commiphora* (Fam. *Burseraceæ*).

Myrrh yields not less than 30 per cent of alcohol-soluble extractive and not more than 4 per cent of acid-insoluble ash.

Description—In roundish or irregular tears or masses, dusty, brownish-yellow or reddish-brown; fracture waxy, somewhat splintery, translucent on the edges, sometimes marked with whitish veins; odor balsamic; taste aromatic, bitter and acrid.

Assay—Proceed as directed under alcohol-soluble extractive, page 1523.

For further description see the U. S. P. X.

U. S. P. Preparation—Tinctura Myrrhæ.

N. F. Preparations—Pilulæ Aloes; Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Pilulæ Rhei Compositæ; Tinctura Aloes et Myrrhæ; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe; Tinctura Capsici et Myrrhæ.

Myrrh is a gum resin, and contains 3 per cent of an oxygenated volatile oil, a bitter principle, about 30 per cent of gum, and 60 per cent of resin. Alcohol is the best solvent for the oil and resin which are its active principles. The gum left after macerating Myrrh in alcohol may be used for making a good mucilage.

Uses—It is used as a local stimulant in diseases of the mouth. Formerly it was also employed in amenorrhea. Dose, eight grains (0.5 Gm.).

TOLU. U.S. Tolu

[Balsamum Tolutanum U. S. P. IX, Balsam of Tolu, Tolu]

Tolu is a balsam obtained from *Toluifera Balsamum* Linné (Fam. *Leguminosæ*).

Description and Physical Properties—A brown or yellowish-brown, plastic solid, transparent in thin layers and brittle when old, dried, or exposed to cold. It has a pleasant, aromatic odor resembling that of vanilla, and a mild, aromatic taste.

Tolu is nearly insoluble in water and in petroleum benzin. It is soluble in alcohol, chloroform, and ether. It dissolves in solutions of the fixed alkalies, usually leaving an insoluble residue.

Tests for Identity and Purity—An alcoholic solution of Tolu (1 in 20) is acid to litmus paper.

Shake about 1 Gm. of Tolu with 25 cc. of carbon disulphide, allow it to stand for thirty minutes, filter the liquid, and evaporate 15 cc. of the filtrate to dryness. The residue thus obtained when dissolved in glacial acetic acid, does not show a green color on the addition of a few drops of sulphuric acid (*rosin*). The remaining portion of the filtrate, when shaken with an equal volume of an aqueous solution of copper acetate (1 in 1000), does not acquire a green color (*rosin or copaiba*).

Dissolve about 1 Gm. of Tolu, accurately weighed, in 50 cc. of neutral alcohol, add 1 cc. of phenolphthalein T.S., and titrate the solution with half-normal alcoholic potassium hydroxide. The acid number thus obtained is not less than 112 and not more than 168, page 1512.

Add sufficient half-normal alcoholic potassium hydroxide to the neutralized liquid obtained in the preceding test to make the total volume of the volumetric alkali solution exactly 20 cc., heat the liquid on a water bath for half an hour under a reflux condenser, and cool. Mix the liquid with 200 cc. of distilled water, or more if necessary, and titrate the excess of potassium hydroxide with half-normal sulphuric acid. The total volume of half-normal potassium hydroxide corresponds to a saponification value of not less than 154 and not more than 220, page 1519.

Tolu contains *cinnamic* and *benzoic acids*, resins, a volatile oil called *benzyl benzoate*, $C_7H_5(C_7H_7)O_2$, *benzyl cinnamate*, *a terpene*, $C_{10}H_{16}$, termed *tolene*, and other constituents of less importance.

U. S. P. Preparations—Syrupus Tolu (from Tincture); Tinctura Benzoini Composita; Tinctura Tolu. It is also used as a pill coating for the following: Pilulæ Ferri Iodidi; Pilulæ Phosphori.

Uses—It is used as a stimulant expectorant in doses of fifteen grains (1 Gm.); also as a pill coating to prevent oxidation.

BALSAMUM PERUVIANUM. U. S. Balsam of Peru

[Bals. Peruv.—Peru Balsam, Indian Balsam]

Balsam of Peru is obtained from *Toluifera Pereiræ* (Royle), Baillon (Fam. *Leguminosæ*).

Description and Physical Properties—A dark brown, viscid liquid, transparent, and appearing reddish-brown in thin layers. It has an agreeable, vanilla-like odor, and a bitter, acrid taste with a persistent after-taste, and is free from stringiness or stickiness. It does not harden on exposure to air.

The Balsam is nearly insoluble in water, but is soluble in alcohol, chloroform, and glacial acetic acid, with not more than an opalescence. It is only partly soluble in ether and in petroleum benzin.

Tests for Identity and Purity—Specific gravity: 1.130 to 1.160 at 25° C.

Water becomes acid to litmus paper when agitated with the Balsam.

One Gm. of the Balsam forms a clear solution when shaken with a solution of 3 Gm. of chloral hydrate in 2 cc. of distilled water (*fixed oils*).

Shake about 1 Gm. of the Balsam with 5 cc. of purified petroleum benzin, and warm the mixture on a water bath for ten minutes, adding a sufficient quantity of the solvent to replace the loss by evaporation. On evaporating 2 cc. of the benzin solution, no odor of oil of turpentine is noticeable (*turpentine*).

Balsam of Peru does not show the presence of *rosin*, page 1519.

Dissolve about 1 Gm. of the Balsam, accurately weighed, in 100 cc. of neutral alcohol, add 1 cc. of phenolphthalein T.S., and titrate the solution with half-normal sodium hydroxide: the acid number thus obtained is not less than 56 and not more than 84, page 1512.

Mix about 3 Gm. of the Balsam, accurately weighed, with 30 cc. of sodium hydroxide T.S. in a separator, shake the mixture for a few minutes with 60 cc. of ether, and allow to stand until complete separation into two layers has taken place. Draw off the lower, aqueous layer and quickly filter the ethereal layer into a flask. Transfer 50 cc. of the ether filtrate (representing five-sixths of the weight of the Balsam taken) to a tared, conical flask, evaporate the ether, and dry the residue at 100° C. for thirty minutes. The weight of the residue of cinnamein so obtained corresponds to not less than 50 per cent and not more than 60 per cent of the weight of the Balsam represented by the 50 cc. of ethereal solution taken. Dissolve this residue in 25 cc. of alcohol, add 25 cc. of half-normal alcoholic potassium hydroxide, and heat the mixture carefully on a water bath for one-half hour, in a flask provided with a reflux condenser. Then add 1 cc. of phenolphthalein T.S., and titrate the excess of alkali with half-normal hydrochloric acid. The amount of half-normal alcoholic potassium hydroxide consumed corresponds to a saponification value for the cinnamein of not less than 235 and not more than 238, page 1519.

N. F. Preparations—Mistura Oleo-Balsamica; Solutio Mastiches Chloroformica Compositum.

Balsam of Peru contains *cinnamic* and *benzoic acids*, *benzyl cinnamate*, $C_9H_7(C_7H_7)O_2$, resin, *benzyl benzoate*, stilbene, etc.

Uses—Balsam of Peru is frequently adulterated, market products having been found which closely resembled the natural drug but which were wholly factitious.

It is chiefly employed externally in sluggish ulcers and in skin diseases. It is also used as a preservative for fats, ointments, etc.; internally, it acts like tolu but is not so pleasant. Dose, fifteen grains (1 Gm.).

BENZOINUM. U. S. Benzoin

[Benzoin.—Gum Benjamin]

Benzoin is the balsamic resin obtained from *Styrax Benzoin* Dryander, known in commerce as Sumatra Benzoin, or from other species of *Styrax*, known in commerce as Siam Benzoin (Fam. *Styraceæ*).

Sumatra Benzoin yields not less than 75 per cent of alcohol-soluble extractive and not more than 1 per cent of acid-insoluble ash. Siam Benzoin contains not more than 1 per cent of foreign organic matter, yields not less than 90 per cent of alcohol-soluble extractive, and not more than 0.5 per cent of acid-insoluble ash.

Description and Physical Properties—

Unground Sumatra Benzoin—Blocks or lumps of varying size, made up of tears, compacted together with a reddish-brown, reddish-gray, or grayish-brown resinous mass; tears externally yellowish or rusty-brown, milky-white on fresh fracture; hard and brittle at ordinary temperatures, but softened by heat and becoming gritty on chewing; odor aromatic. When digested with boiling water the odor suggests cinnamic acid or storax. Taste aromatic and slightly acrid.

Unground Siam Benzoin—Pebble-like tears of variable size, compressed, yellowish-brown to rusty-brown externally, milky-white on fracture, separate or very slightly agglutinated, hard and brittle at ordinary temperatures but softened by heat and becoming plastic on chewing; odor agreeable, balsamic, vanilla-like; taste aromatic and slightly acrid.

Tests for Identity—The solution of Benzoin in alcohol becomes milky upon the addition of water and is acid to litmus paper.

Heat a few fragments of Benzoin in a test tube: Sumatra Benzoin evolves a sublimate, consisting of plates and small, rod-like crystals that strongly polarize light. Siam Benzoin evolves a sublimate directly above the melted mass consisting of numerous long, rod-shaped crystals, which do not strongly polarize light.

Treat about 0.25 Gm. of Benzoin with 5 cc. of ether, decant about 1 cc. of the ethereal solution into a porcelain dish, and add to it 2 or 3 drops of sulphuric acid: the solution of Sumatra Benzoin produces a deep red-brown coloration of the sulphuric acid and the solution of Siam Benzoin produces a deep purplish-red coloration.

Heat about 0.5 Gm. of Benzoin in a test tube with 10 cc. of potassium permanganate T.S.: only the Sumatra variety develops an odor of benzaldehyde.

Treat about 1 Gm. of powdered Benzoin with 15 cc. of warm carbon disulphide, filter, wash the filter with an additional 5 cc. of carbon disulphide, and allow the filtrate to evaporate spontaneously: the residue is not less than 12.5 per cent. This residue responds to the tests for identity under *Acidum Benzoicum*.

Tests for Purity—Benzoin does not show the presence of *rosin*, page 1519.

Assay—Proceed as directed under alcohol-soluble extractive (page 1523).

U. S. P. Preparations—(From Siam Benzoin) Adeps Benzoinatus. (From any official Benzoin) Tinctura Benzoini; Tinctura Benzoini Composita.

N. F. Preparations—Sevum Benzoinatum; Unguentum Picis Compositum (from Tincture).

Benzoin contains *benzoic acid*, *cinnamic acid* ($C_9H_8O_2$), a fragrant volatile oil, and resins. In some varieties *vanillin* is found. Alcohol is the best solvent for its active principles.

Uses—It is employed chiefly as a local remedy for irritations of the skin. It was formerly used externally as an expectorant. Dose, fifteen grains (1Gm.).

STYRAX. U.S. Storax

[Liquid Storax]

Storax is a balsam obtained from the trunk of *Liquidambar orientalis*, Miller, known in commerce as Levant Storax, or of *Liquidambar styraciflua* Linné, known in commerce as American Storax (Fam. *Hamamelidaceæ*.).

Description and Physical Properties—A semi-liquid, grayish to grayish-brown, sticky, opaque mass, depositing on standing a heavy, dark brown layer (Levant Storax); or a semi-solid, sometimes a solid mass, softened by gently warming (American Storax). Storax is transparent in thin layers, has a characteristic odor and taste, and is heavier than water.

Storax is insoluble in water, but is soluble, usually incompletely, in an equal weight of warm alcohol. It is also soluble in acetone, carbon disulphide, and ether, some insoluble residue usually remaining.

Tests for Identity and Purity—To about 0.05 Gm. of the cinnamic acid obtained in the assay add 5 cc. of diluted sulphuric acid, heat, and add potassium permanganate T.S.: the odor of benzaldehyde is evolved. A portion of the acid recrystallized from hot water melts between 134° and 135° C.

Dry about 2 Gm. of well-mixed Storax, accurately weighed, for two hours at 100° C.; the loss in weight does not exceed 20 per cent.

Dissolve about 10 Gm. of well-mixed Storax, accurately weighed, in 40 cc. of hot alcohol, filter through counterbalanced filters or a Gooch crucible, and wash the residue with small por-

tions of hot alcohol until the washings are colorless or very nearly so: the residue after drying at 100° C. does not exceed 5 per cent. Evaporate the combined alcoholic filtrate and washings at a temperature not exceeding 60° C., and dry the residue for one hour at 100° C.: a yellow to brown residue of purified Storax remains, corresponding to not less than 70 per cent of the weight of the Storax taken. The purified Storax thus obtained complies with the following tests:

Dissolve about 1 Gm. of the purified Storax, accurately weighed, in 50 cc. of neutralized alcohol, add 0.5 cc. of phenolphthalein T.S., and titrate with half-normal sodium hydroxide: the acid number is from 56 to 85 for Levant Storax and from 38 to 85 for American Storax, page 1512.

Place about 2 Gm. of the purified Storax, accurately weighed, in a 250 cc. flask, mix with 50 cc. of purified petroleum benzin, add 25 cc. of half-normal alcoholic potassium hydroxide, and allow the mixture to stand twenty-four hours with frequent agitation. Then add 0.5 cc. of phenolphthalein T.S. and titrate the excess of alkali with half-normal hydrochloric acid. The saponification value thus obtained is not less than 160 and not more than 200, page 1519.

Boil about 2 Gm. of the purified Storax, accurately weighed, with 25 cc. of half-normal alcoholic potassium hydroxide for one hour under a reflux condenser. Neutralize with half-normal sulphuric acid, using 5 drops of phenolphthalein T.S. as indicator, and evaporate the alcohol on a water bath. Dissolve the residue in 50 cc. of distilled water and shake the solution with 20 cc. of ether. Shake the separated ether with 5 cc. of distilled water, add the washings to the aqueous solution, and reject the ether-extract. Add to the aqueous solution 10 cc. of diluted sulphuric acid and shake with four successive portions of 20 cc. each of ether. Wash the combined extract with 5 cc. of distilled water, rejecting the water washings, transfer to a flask and distil off the ether. Add to the residue 100 cc. of distilled water, and boil vigorously for fifteen minutes under a reflux condenser. Filter while hot and allow the filtrate to cool to about 25° C: white crystals of cinnamic acid separate. Filter the cinnamic acid on a Gooch crucible, applying a vacuum towards the end to drain the crystals completely. Repeat the extraction of the residue twice by boiling each time under a reflux condenser, as before described, with the filtrate from the preceding crystallization, and collect the additional cinnamic acid in the same crucible. Finally wash the cinnamic acid with two 10 cc. portions of ice cold water, dry at 80° C., and weigh. The weight of the cinnamic acid thus obtained corresponds to not less than 25 per cent of the purified Storax taken.

U. S. P. Preparation—Tinctura Benzoini Composita.

Storax contains cinnamic acid, benzoic acid, *styracin*, $C_9H_7(C_9H_9)O_2$, *storesin*, $C_{36}H_{57}O_3$, *ethyl cinnamate*, $C_9H_7(C_2H_5)O_2$, *phenyl-propyl cinnamate*, $C_9H_7(C_9H_{17})O_2$, *styrol*, C_8H_8, a fragrant hydrocarbon, and a resinous substance not yet investigated. A large quantity of water is usually present.

Uses—It is an expectorant but is used chiefly as a local remedy, especially in combination with benzoin. It may be used, like benzoin, to protect fatty substances from rancidity. Dose, fifteen grains (1 Gm.).

ACIDUM BENZOICUM. U. S. Benzoic Acid

Benzoic acid and its compounds which are largely prepared synthetically will be found on pages 832 to 839.

AGARICUS. N. F. Agaric

[White Agaric, Larch Agaric]

Agaric is the dried fruit of *Polyporus officinalis* Fries (Fam. *Polyporaceæ*) deprived of its outer rind.

Agaric contains not more than 5 per cent of foreign organic matter. It yields to boiling alcohol not less than 50 per cent of a non-volatile resinous extract.

It contains an active principle known as *agaracin*, also resin.

Description—Light, fibrous, somewhat spongy pieces of irregular shape; grayish-white to pale brown externally; yellowish and resinous internally; fracture tough, fibrous; friable but difficult to powder. Odor faint; taste sweetish, acrid, and bitter.

For further description see the N. F. V.

N. F. Preparations—Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe.

Uses—Used to control the night sweats of phthisis, in doses of five to ten grains (0.3 to 0.6 Gm.).

EUCALYPTI GUMMI. N. F. Eucalyptus Gum

[Eucalypt. Gum.—Red Gum]

Eucalyptus Gum is a dried gummy exudation from *Eucalyptus rostrata* Schlecht, and other species of *Eucalyptus* (Fam. *Myrtaceæ*).

Description—In dark reddish-brown grains or angular masses which in thin layers are of a transparent ruby-red color; brittle, the older surfaces sometimes dusty; forming a plastic mass and adhering to the teeth when chewed, coloring the saliva red; odor slight; taste very astringent. For further description and tests see the N. F. V.

Preparation—Trochisci Eucalypti Gummi.

Uses—A mild astringent in diarrhea but most frequently employed in lozenges and gargles to relieve a relaxed condition of the pharynx.

Dose, 10 grains (0.6 Gm.).

GUAIACUM. N. F. Guaiac
(U. S. P. IX)

[**Guaiac.**—Guaiac Resin]

Guaiac is the resin of the wood of *Guaiacum officinale* Linné, or of *Guaiacum sanctum* Linné (Fam. *Zygophyllaceæ*).

Guaiac yields not more than 15 per cent of residue insoluble in alcohol.

Description—In irregular fragments or in large, nearly homogeneous masses, occasionally in more or less rounded or ovoid tears, enclosing fragments of vegetable tissues; externally brown, becoming greenish-gray-brown on exposure, the fractured surface having a glassy luster, the thin pieces being translucent and varying in color from reddish to yellowish-brown. Odor balsamic; taste slightly acrid.

For further description see the N. F. V.

N. F. Preparations—Gargarisma Guaiaci Composita (from Ammoniated Tincture); Tinctura Guaiaci; Tinctura Guaiaci Ammoniata; Tinctura Guaiaci Composita.

This resin is usually prepared by boiling guaiac chips in salt water; the resinous scum is collected, melted, and strained. It consists of *guaiacic acid* ($C_{12}H_{16}O_6$), *guaiaconic acid* ($C_{19}H_{20}O_5$), *guaiaretic acid* ($C_{20}H_{26}O_4$), beta resin, gum, etc. Alcohol and alkaline solutions are the best solvents for guaiac. A solution of guaiac resin is colored blue by oxidizing agents, due to the presence of guaiaconic acid.

History—This drug came into use in the early part of the sixteenth century in the treatment of syphilis. It was so highly extolled that it sold for a price equivalent to $25 a pound.

Uses—Guaiac is used as a remedy in rheumatism in doses of fifteen grains (1 Gm.). It is a valuable reagent in one of the tests for occult blood.

DIOSCOREA. N. F. Dioscorea

[**Diosc.**—Wild Yam Root]

Dioscorea is the dried rhizome of *Dioscorea villosa* Linné (Fam. *Dioscoreaceæ*).

Dioscorea contains not more than 2 per cent of foreign organic matter.

Description—Knotted and woody, elongated, from 6 to 12 mm. in thickness, often compressed, bent and branched, bearing scattered nodular projections at the sides, slender tough roots underneath and stem-scars on the upper surface; externally pale brown, surface more or less scaly from the partly detached, thin outer layer; fracture short but tough, the fractured surface whitish or pale-brown, with numerous small, scattered, yellowish wood bundles. Odorless, taste starchy, insipid, afterwards acrid.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Dioscoreæ; Tinctura Viburni Opuli Composita.

Uses—It has been used in hepatic disorders and also in rheumatism. Dose, one drachm (4 Gm.).

DROSERA. N. F. Drosera

[**Droser.**—Sundew]

Drosera is the air-dried flowering plant of *Drosera rotundifolia* Linné, frequently mixed with the closely allied species *Drosera anglica* Hudson and *Drosera longifolia* Linné, or at times wholly replaced by these (Fam. *Droseraceæ*).

Drosera contains not more than 5 per cent of foreign organic matter and yields not more than 10 per cent of acid-insoluble ash.

It contains an acrid resin, citric and malic acids and a ferment.

Description—A delicate plant of a reddish color throughout, with a few fibrous, blackish rootlets; leaves all in a basal rosette, blade orbicular, about 15 mm. in diameter, abruptly contracted into a slender, pubescent petiole, upper surface covered with prominent glandular hairs; scape filiform, smooth, from 10 to 20 cm. in length, bearing a few, five-parted, small, white fugacious flowers in a curved, one-sided raceme.

Drosera intermedia is identified by its spatulate leaves with blades two or three times as long as they are wide and glabrous petioles. *Drosera longifolia* is identified by its elongated spatulate obovate leaves with blades six or eight times as long as they are wide, and its slender smooth petioles and scape, declinate at base. Odorless; taste faintly bitter and acidulous.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Droseræ.

Uses—It is used in chronic bronchitis, whooping-cough, and tuberculosis, but is apparently of little value. Dose, one drachm (4 Gm.).

ECHINACEA. N.F. Echinacea

[Echin.]

Echinacea consists of the dried rhizome and roots of *Brauneria pallida* (Nuttall) Britton or *Brauneria angustifolia* (De Candolle) Heller (Fam. *Compositæ*).

Echinacea contains not more than 3 per cent of foreign organic matter. Echinacea must not be used after it has lost its characteristic odor and taste.

It contains an acrid resin, and a minute amount of an alkaloid.

Description—Nearly entire, cylindrical, very slightly tapering and sometimes slightly spirally twisted, from 10 to 20 cm. in length and from 4 to 13 mm. in diameter, externally grayish-brown, light brown or purplish-brown, slightly annulate in the upper portion, with occasional V-shaped stem scars, somewhat longitudinally wrinkled or furrowed; fracture short, fibrous, bark less than 1 mm. in thickness, wood thick and composed of alternate light yellowish and black wedges; the rhizome with a circular pith. Odor faint, aromatic; taste sweetish, followed by a tingling sensation suggesting aconite, but lacking the persistent and benumbing effect produced by that drug.

For further description see the N. F. V.

N.F. Preparation—Fluidextractum Echinaceæ.

Uses—It is used as an alterative, and as a diaphoretic; also used in eczema. Dose, fifteen grains (1 Gm.).

EUPHORBIA. N.F. Euphorbia

[Euphorb.—Euphorbia Pilulifera—Pill Bearing Spurge]

Euphorbia is the dried herb of *Euphorbia herta* Linné (Fam. *Euphorbiaceæ*).

Euphorbia contains not more than 5 per cent of foreign organic matter and yields not more than 3 per cent of acid-insoluble ash.

It contains an acrid resin.

Description—Roots usually present, small, branched, and reddish; stems slender, cylindrical, obliquely erect, dichotomously branched from near the base, branches recurved at apices; branches and stem only sparsely leafed at base, pale greenish-brown, rough or hairy; stems coarsely pilose with yellow hairs which are rather dense on the upper parts but sparse on the lower; pubescence consisting of short, nearly straight unicellular hairs, becoming almost hispid at the flowering tops; leaves opposite, obliquely oblong, acute, serrulate, rusty pale green, pubescent especially on the prominent veins on the lower surface, becoming brittle on drying and usually much broken in the drug; flowers small, numerous, in short peduncled axillary clusters; fruits about 1 mm. in diameter, three-celled capsules, seeds about 0.9 mm. in diameter, triangular ovoid, pale brown. Odor aromatic, and characteristic; taste faintly bitter, aromatic, and acrid.

For further description see the N. F. V.

N.F. Preparation—Fluidextractum Euphorbiæ Piluliferæ.

Uses—It is used as an expectorant. Dose, thirty grains (2 Gm.).

KAVA. N.F. Kava

[Kav.—Methysticum—Kava Kava]

Kava is the dried rhizome and roots of *Piper methysticum* Forster (Fam. *Piperaceæ*).

Kava contains not more than 1 per cent of foreign organic matter.

Its chief constituent is a resin present to the extent of about 5 per cent. Small amounts of other principles, glucosidal and alkaloidal in character, are said to be present.

Description—It consists of a large, irregular knotty crown, often 12 cm. or more in diameter, from which proceed numerous, long, cylindrical, tough, nearly simple roots, which tend to fray out into bare, separated fibro-vascular bundles; the crown soft, light, spongy and granular and very starchy; externally dark-brown or blackish, the crown frequently partly scraped and light brown to light gray; internally white. Odor faint but characteristic; taste aromatic and pungent slightly bitter, more or less local anesthesia resulting.

For further description see the N. F. V.

N.F. Preparation—Fluidextractum Kavæ.

Uses—A stimulant diuretic. The dose is fifteen grains (1 Gm.).

MASTICHE. N.F. Mastic

(U.S.P. VIII)

Mastic is a concrete resinous exudation from *Pistacia lentiscus* Linné (Fam. *Anacardiaceæ*).

Mastic contains not more than 1 per cent of foreign organic matter.

Mastic contains a resin (mastichic acid, $C_{20}H_{32}O_2$), which is soluble in strong alcohol; also masticin, a resinous principle which is insoluble in alcohol; a small quantity of volatile oil is likewise present.

Description—In sub-globular, lenticular, elongated or pear-shaped tears, about 3 mm. in diameter, pale yellow or greenish-yellow, transparent, having a glass-like luster, the surface sometimes very slightly dusty; brittle, becoming plastic when chewed. Odor slight, balsamic; taste mild, terebinthinate.

For further description see the N. F. V.

N. F. Preparations—Pilulæ Aloes et Mastiches; Solutio Mastiches Chloroformica Compositum.

Uses—It is used in pills of aloes and mastic to modify the action of the aloes; in the arts and in dentistry it is employed to form a varnish. Dose, thirty grains (2 Gm.).

MITCHELLA. N. F. Mitchella

[**Mitchel.**—Squaw Vine]

Mitchella is the dried plant of *Mitchella repens* Linné (Fam. *Rubiaceæ*).

Mitchella contains not more than 5 per cent of foreign organic matter.

Description and Tests—(See the N. F. V.)

It contains resin, wax, and mucilage, and a saponin-like principle.

Preparations—Elixir Aletridis Compositum, Elixir Heloniadis Compositum, Fluidextractum Mitchellæ.

Uses—A diuretic, tonic, and astringent. *Dose*, 30 grains (2 Gm.).

PINUS ALBA. N. F. White Pine Bark

[**Pin Alb.**]

White Pine Bark is the dried inner bark of *Pinus Strobus* Linné (Fam. *Pinaceæ*).

White Pine Bark contains not more than 2 per cent of outer bark and not more than 2 per cent of foreign organic matter.

It contains tannin, gum, resin, and a peculiar body known as *coniferin*, ($C_{16}H_{22}O_8.H_2O$). This substance yields vanillin upon oxidation.

Description—In flat pieces of variable size and from 1 to 3 mm. in thickness; outer surface varying from a pale pinkish-white when fresh, to a light or rather deep-yellowish brown on keeping, occasionally with small patches of the gray-brown periderm adhering; more or less cottony, and often showing small scattered pits; inner surface either lighter or darker than the outer, finely striate; fracture tough, fibrous; transverse section showing an outer yellowish and an inner whitish band. Odor slight, terebinthinate; taste slightly mucilaginous, bitter, sweet, and astringent.

For further description see the N. F. V.

N. F. Preparations—Syrupus Pini Albæ Compositus; Syrupus Pini Albæ Compositus cum Morphina.

Uses—It is used as an expectorant in doses of thirty grains (2 Gm.).

Unofficial Products from Oils and Substances Containing Resins

Ammoniacum Ammoniac. (U. S. P. 1890)	A gum-resin obtained from *Dorema Ammoniacum* Don (Fam. *Umbelliferæ*). It contains 25 per cent gum, 70 per cent resin, and about 3 per cent volatile oil. It is expectorant and stimulant. Dose, fifteen grains (1 Gm.)
Bdellium Bdellium	From *Balsamodendron Mukul*, grown in India. It contains volatile oil and resin
Benzoyl Glycocoll, $CH_2 \begin{matrix} NH.C_7H_5O \\ COOH \end{matrix}$	The dose of benzoyl glycocoll, or *sodium hippurate*, is ten grains (0.65 Gm.) three times a day
Copal	A resinous substance, brought principally from the East Indies. Used for making varnish
Doundaké	An astringent and tonic febrifuge
Elastica, Rubber (India Rubber U. S. P. VIII)	The prepared milk-juice of several species of *Vebea* Aublet (Fam. *Euphorbiaceæ*), known in commerce as Para Rubber. It is used as the base for machine-made plasters
Elemi Elemi	From *Cannarium commune*, grown in the Philippine Islands. It contains 10 per cent of volatile oil, $C_{10}H_{16}$, and 25 per cent of resin
Euphorbium Euphorbium	From *Euphorbium resinifera*, found in Morocco. It contains 18 per cent of gum and 38 per cent of resin, etc.
Galbanum Galbanum	From *Ferula galbaniflua*. It contains 8 per cent of volatile oil and 85 per cent of resin. Dose, fifteen grains (1 Gm.)
Guaiac Wood Lignum Vitæ (N. F. IV)	The heart-wood of *Guaiacum officinale* Linné or of *Guaiacum sanctum* Linné (Fam. *Zygophyllaceæ*). The chief constituent is the resin which is official in the N. F. Used as a remedy in rheumatism in doses of one drachm (4 Gm.)
Gurjun Wood Oil	From *Dipterocarpus turbinatus*. It contains about 40 per cent of volatile oil and resin
Gutta Percha (N. F. IV)	The purified, coagulated, milky exudate of various trees of the genus *Palaquium* Blanco (Fam. *Sapotaceæ*). An adhesive, used for the preparation of Gutta Percha solution
Gutta Percha Solution (N. F. IV)	Prepared by dissolving 15 Gm. of gutta percha in 75 cc. of chloroform, adding 17 Gm. of lead carbonate previously mixed with 25 cc. of chloroform. Shake the mixture thoroughly and set it aside to clarify by subsidence.
Hippuric Acid, ($C_9H_9NO_3$)	Suggested as a remedy in the uric acid diathesis
Labdanum Labdanum	A stimulant expectorant. At present used only in plasters
Lac Lacca	A reddish-brown resin. Formerly used in medicine, but at present chiefly for making varnish; also in making sealing wax

Unofficial Products from Oils and Substances Containing Resins—*Continued*

Olibanum Frankincense	From several species of *Boswellia*, found in Africa. It contains 6 per cent of volatile oil and 56 per cent of resin
Pix Burgundica Burgundy Pitch (U. S. P. 1890)	The prepared resinous exudation of *Abies excelsa* Poiret (Fam. *Coniferæ*). Used in making plasters
Pix Canadensis Canada Pitch	From *Abies canadensis*. Used in making plasters
Resina Draconis Dragon's Blood	The resin from the fruit of *Calamus Draco*. It contains a peculiar resin, $C_{20}H_{20}O_2$, etc.
Retinol	A yellowish oil, boiling at 280° C. (536° F.) Mildly antiseptic. Good solvent of phosphorus
Sagapenum	Stimulant, antispasmodic. Dose, ten to thirty grains (0.65 to 2 Gm.). Used also externally in plasters as a discutient
Sandarach Gum Juniper	Used chiefly as a varnish and as incense. Formerly given internally, and used in ointments and plasters
Succinum Amber	Contains succinic acid, and a volatile oil which is stimulant and antispasmodic, or rubefacient when applied externally
Terebinthina Canadensis Canada Turpentine (Balsam of Fir Canada Balsam U. S. P. VIII)	A liquid oleoresin obtained from *Abies balsamea* (Linné) Miller (Fam. *Coniferæ*) (see Reagents, Part IX). Used externally but chiefly for mounting microscopic objects
Terpinol, $(C_{10}H_{16})_2 + H_2O$	Derivative of oil of turpentine. In colorless crystals. Dose, three to four grains (0.2 to 0.25 Gm.)
Venice Turpentine Larch Turpentine (N. F. IV)	A viscid oleoresin obtained from *Larix europæa* De Candolle (Fam. *Pinaceæ*). A nearly transparent, yellowish or yellowish-green, thick liquid, heavier than water. It is used as a stimulant diaphoretic and diuretic
Viscum Album Mistletoe	Oxytocic. Dose, one fluidrachm (4 cc.) of the fluidextract

Eclectic Resinoids

Prof. John Uri Lloyd has supplied the following statement concerning these products:

"Following the discovery of resin of podophyllum, made by Dr. John King and announced to the medical and pharmaceutical professions nearly one hundred years ago (1835), Wm. S. Merrill, a manufacturing pharmacist of Cincinnati, Ohio, introduced the preparation commercially. Came then an idealistic view of similar possibilities with other drugs of the American materia medica.

Soon afterward Doctor King introduced resin of cimicifuga (macrotys) known as *macrotin*, which was the second authentic "Eclectic Resinoid".

The service of resin of podophyllum, which rapidly grew into use, was of exceptional importance. It practically displaced scammony and resin of jalap. Thus, as an example, the term "Compound Cathartic Pills Improved" resulted.

Manufacturers were led illogically to attempt to parallel these resins with products from other plants. As a distinguishing feature the commercial term "*in*" affixed to the word was employed, thus King's resin of podophyllum was commercially changed to *podophyllin*, the same rule being applied elsewhere.

Doctor King did not utilize this commercial termination, *in*, stating—"as to the nomenclature given to these resins and dried extracts, it did not originate with me."

Within a reasonable time the commercial market was weighted with dried extracts and heterogeneous materials listed as "Eclectic resinoids, alkaloids, and concentrations". Few had originated with physicians of the Eclectic school.

Finally aroused by the frauds, the illogical and unfounded claims made by affixing the word "Eclectic" to this large class of heterogeneous preparations, it became necessary to deal a death blow to the products and their connection with the school. This was accomplished so far as the Eclectic School of Medicine was concerned by Doctor King. In the Worcester Journal of Medicine, 1855, he wrote as follows:

'I now wish to call the attention of all classes of physicians to a most stupendous fraud which is being perpetrated upon them in relation to concentrated preparations, in which oils, oleo-resins, fluidextracts, etc., are triturated with finely powdered green leaves, or roots, or barks, perhaps of the crude articles of which they purport to be concentrations, as well as with rosin, carbonate of magnesia, etc. The resin of jalap which can be obtained for two dollars a pound, is triturated with some inert agent, and sold for Jalapin at one dollar an ounce; and similar impositions.

I regret that I am compelled to thus definitely allude to these matters, but there is no help for it—the cause of Eclecticism, of truth, of justice, demands it. Already are the old school physicians manifesting an interest in our concentrated remedies, and if we permit such trash to be foisted on them as pure agents, they will believe that Eclecticism is indeed quackery and humbug, and it will require years to overcome the effects of such a disgraceful blow. We have sufficient to do in contending for the truth and justice of our cause, without warring against the imposition of those who either directly or indirectly claim to be with us.

I am sorry to say some individuals have been found so far regardless of the good of the cause, and of their own honor, as to have made strenuous efforts to introduce these agents to the profession by all the means in their power.

I shall make no comments on the subject; it speaks for itself with the voice of a stentor, and every honorable man, every true Eclectic, can not but feel its voice enkindling within his whole soul the strongest feelings of censure and indignation toward those who would thus deceive the profession in a matter so intimately connected with the health and lives of their fellow creatures.—John King.

In 1870, fortifying the foregoing, Dr. John M. Scudder struck another blow, the two together practically ending the use of these compounds with the exception of the Resin of Podophyllum, Macrotys and a few legitimates used by physicians of the Eclectic school.

Dr. Scudder wrote: In 1855 much of Eclectic medicine was an unmitigated humbug. That was the day of the so-called *concentrated medicines*, and anything having a termination in *"in"* was lauded to the skies. It was claimed that these resinoids were the active principles of the plants, and as they would replace the old drugging with crude remedies and teas, they must prove a great boon. But they did not give success, and finally, after trying them for awhile, the practitioner would go back to the crude articles and old syrups and teas with success, or he would settle down to podophyllin catharsis and quinine.'

Yet the term Eclectic resinoids, alkaloids and concentrations, affixed to a class of preparations that Eclecticism never fathered, never commended and in no wise originated, continued to be applied in print as their introduction.

To the foregoing it should be added that the alkaloidal products of certain alkaloid-yielding plants, such as sanguinaria and hydrastis, have been and are yet standard remedial agents in the Eclectic medical fraternity. They have been accepted the world over as strictly scientific.

At the risk of being considered an unwanted personal intrusion, the following from my pen, printed in 1909 in a treatise on the subject, is quoted:

'*The Lesson*—Comes now the lesson taught by near a century of turmoil in and among alkaloids, resins, resinoids, and oleo-resins. Shattered ambitions, blasted hopes, disappointments generally, have their uses. The resinoid craze is not an exception, for it has already served several purposes, one being the establishing of the fact that in only a few North American drugs are found alkaloids or resins of great individual merit, another being the dispelling of the illusion that a fragment can parallel the whole, if the whole be intelligently comprehended. Eclectic physicians learned from an experience not easily forgotten the lesson that dried fragments of drugs are not representatives of drugs'".

CHAPTER LXXI

FIXED OILS, FATS, SOAPS, AND PETROLEUM PRODUCTS

FIXED oils and fats are, with few exceptions, esters of the higher members of the paraffin series of fatty acids with the radical glyceryl, and are sometimes called glycerides of the fatty acids. The difference between fixed and volatile oils therefore is a very vital difference. The volatile oils have no uniformity or similarity in their general composition, their volatility being their common distinguishing character. The fixed oils, besides the similarity of their composition, are non-volatile, except when heated to the point of decomposition.

The difference between fixed oils and fats is one of consistence, the fats being harder, owing to variations in the proportions of certain constituents common to both. Waxes resemble both fats and fixed oils in that they are esters of fatty acids, but they differ in that instead of being esters of glyceryl, they are esters of higher alcohols (see Cera Flava, page 1191). Fats and oils are sometimes referred to as *lipoids* or *lipides*.

Fixed oils and fats are distinctive in their physical properties. They are greasy to the touch and leave a permanent oily stain upon filter paper. They are all lighter than water and insoluble therein, but are soluble in ether, chloroform, and other immiscible solvents. A few of them are soluble in alcohol.

When purified, they are nearly colorless and of a bland odor and taste, with very little distinctiveness.

When heated moderately, fats liquefy and oils become thinner. When heated strongly, they undergo decomposition with the production of acrid, inflammable vapors and when ignited, burn with a sooty flame. The acridity of an overheated fixed oil or fat is due to the liberation of *acrolein* (*acrylic aldehyde*).

Upon exposure to air and moisture, a peculiarly disagreeable quality is developed which is known as *rancidity* and which is usually accompanied by the liberation or formation of lower members of the series of fatty acids, known as volatile fatty acids. Rancidity may be retarded by keeping fixed oils and fats in a cool, dry place in well-filled dry containers, protected from light. When rancidity has occurred, it may sometimes be removed by careful treatment of the oil with weak alkalies and subsequent additional purification.

Most of the fixed oils and fats are obtained by expression from the plant or animal tissues in which they occur. Generally the material is prepared by grinding and is subsequently submitted to hydraulic pressure.

The oils as obtained by the first expression usually are of the highest commercial value, as in olive oil where the first pressings are called "virgin" olive oil, but sometimes the expressed oil from plant tissues is crude in its character and requires subsequent treatment and purification, as in the case of cottonseed oil. Fixed oils and fats are frequently bleached by treatment with fuller's earth or similar clays, and subsequent filtration.

Some few oils for technical purposes are not obtained by expression but are extracted from the plant tissues by means of volatile solvents which are later recovered. Animal fats and oils are usually separated by the process known as "rendering" which consists in melting the tissues until the fat separates mechanically.

There are several proximate constituents which are common to many fixed oils. They are *olein*, *palmitin*, and *stearin*.

A fat or oil containing all three of these constituents might be called an *oleo-palmito-stearate of glyceryl.*

Olein is *glyceryl trioleate* [$C_3H_5(C_{18}H_{33}O_2)_3$]. It is liquid at ordinary temperatures. It predominates in expressed oil of almond and in lard oil.

It is the predominating constituent in the more fluid oils of animal and vegetable origin and is separated and purified by cold expression, the other constituents being retained by their lack of fluidity at low temperatures. It is insoluble in water but soluble in alcohol and in ether.

Palmitin is *glyceryl tripalmitate* [$C_3H_5(C_{16}H_{31}O_2)_3$]. It is semi-solid at ordinary temperatures. It predominates in palm oil, coconut oil, and in some waxes.

Stearin is *glyceryl tristearate* [$C_3H_5(C_{18}H_{35}O_2)_3$]. It is solid at ordinary temperatures. It predominates in solid fats and is separated by cold expression, which removes the olein and palmitin.

A constituent called *margarin* was at one time believed to exist in fats but this was later discovered to consist of a mixture of palmitin and stearin.

A glance at the chemical formulas of olein and stearin will show their close similarity, stearin containing two more atoms of hydrogen in each molecule. Olein is now capable of being converted into stearin by a process known as *hydrogenation* which consists in the action upon olein, of nascent hydrogen in the presence of a catalyst, such as finely divided nickel. Liquid oils are now commercially transformed into solid fats which are much more valuable. *"Crisco"*, the proprietary cooking fat, is an example of a hydrogenated fat; it is made from cottonseed oil.

Oils and fats, when subjected to pressure at certain temperatures, can be fractionated into the foregoing constituents: olein, palmitin, and stearin. In the natural change which takes place in most fluid oils upon standing, the stearin has a tendency to precipitate and make the oil unsightly and less valuable.

In the days before artificial refrigeration the oils expressed in the summer (at a higher temperature), when the stearin would be kept in solution to a greater extent, were found to deposit the stearin much more readily than those pressed in the winter (at a lower temperature), and *"summer pressed"* and *"winter pressed"* were commercial designations which still obtain, although at the present time it is a matter of temperature control at the time of pressing, irrespective of the season.

Fixed oils are classified into drying and non-drying oils. The former when exposed to the air undergo oxidation with the formation of a tough hard film. Linseed oil is an example of the class of drying oils which find their greatest use in the manufacture of paints and varnishes. The non-drying oils when exposed to the air remain sticky to the touch for an indefinite period and therefore cannot be used in paints and varnishes. Olive oil and the expressed oil of almond are examples of non-drying oils. The drying or non-drying quality is caused by the presence, in the former class, of unsaturated fatty acids of a distinctive character.

The analytical factors of importance in identifying fixed oils and in judging of their quality, are the iodine number, acid number, saponification number, and refractive index. The specific gravity, color, odor, and congealing point are of little or no value. Some oils, such as cottonseed oil and sesame oil, are identifiable by specific tests, but the identification of a fixed oil is only inferentially possible as a rule, after taking all physical and chemical factors into account.

The common property of all fats and oils is that of undergoing saponification when treated with alkalies. (See under Glycerin, Lead Plaster, Soap, Soft Soap, etc.)

OLEUM AMYGDALÆ EXPRESSUM. U. S. Expressed Oil of Almond

[Ol. Amygd. Exp.—Oil of Sweet Almond]

The fixed oil obtained from the kernels of varieties of *Amygdalus communis* Linné (Fam. *Rosaceæ*).

Preparation—This oil is obtained equally pure from sweet and bitter almonds. The almonds, having been deprived of a reddish-brown powder adhering to their surface, by being rubbed together in a piece of coarse linen, are ground in a mill, and then pressed in canvas sacks between plates of steel slightly heated. The oil, which is at first turbid, is clarified by rest and filtration. Sweet almond yields about 40 per cent and bitter almond 35 per cent of fixed oil.

A colorless oil may be obtained by expressing almonds which have been *blanched—i.e.*, deprived of their testa by soaking them in hot water and slightly pressing them, and afterwards drying in a stove to evaporate the water. The fixed oil from peach or apricot kernels is frequently sold for expressed oil of almond; it is commercially known as *Oleum persica*. While a useful product, it is not intended by the U. S. P. that it should be substituted for oil of sweet almond (see official test below).

The *sweet almond, Amygdala dulcis*, was official in the U. S. P. IX. It contains about 40 per cent of fixed oil, protein substances (*conglutin* and *amandin*), sugar and mucilage.

The integument must be removed by placing the seeds in boiling water for a moment before preparing the emulsion (see page 290).

Description and Physical Properties—A clear, pale straw-colored or colorless, oily liquid. It is almost odorless, and has a bland taste.

It is slightly soluble in alcohol, but is miscible with ether, chloroform, benzene, and with petroleum benzin.

Tests for Identity and Purity—Specific gravity: 0.910 to 0.915 at 25° C.

The Oil remains clear at −10° C., and does not congeal until cooled to nearly −20° C. (*olive or lard oil*).

Shake vigorously, for five minutes, 2 cc. of the Oil with a mixture of 1 cc. of fuming nitric acid and 1 cc. of distilled water: the mixture is not more than slightly colored. (*Oil of peach kernels and oil of apricot kernels* yield a red color, and *sesame oil and cottonseed oil* yield a brown color.)

Heat 10 cc. of the Oil with 15 cc. of an aqueous solution of sodium hydroxide (1 in 6) and 30 cc. of alcohol on a water bath in a flask, having a small funnel inserted in the neck, and occasionally agitate the mixture until it becomes clear. Transfer the solution to a shallow dish, and evaporate the alcohol on a water bath: the residue, when mixed with 100 cc. of distilled water, produces a clear solution (*paraffin oil*). Add an excess of hydrochloric acid to this solution: a layer of oleic acid rises to the surface which, when separated, washed with warm water, clarified by heating on a water bath, and cooled to 15° C. remains clear for thirty minutes (*various foreign oils*).

One volume of the oleic acid obtained in the preceding test, when mixed with an equal volume of alcohol, yields a clear solution, which, at 15° C., does not deposit any fatty acids, or become turbid upon the further addition of 1 volume of alcohol (*difference from olive, peanut, cottonseed, sesame, and other fixed oils*).

Saponification value: not less than 191 and not more than 200, page 1519.

Iodine value: not less than 93 and not more than 100, page 1519.

Preserve in well-closed containers.

U. S. P. Preparation—Unguentum Aquæ Rosæ.

N. F. Preparations—Emulsum Petrolati; Oleum Phosphoratum; Unguentum Veratrinæ.

The press cake obtained as a by-product in the manufacture of expressed oil of almond is sometimes recommended as a food product for use by diabetics on account of its high protein and low carbohydrate content. The pharmacist must exercise care in selling almond meal for this purpose that bitter almond

meal which is poisonous is not supplied. Under the name of almond meal a spurious article consisting of corn meal, soap, etc., is marketed for detergent and cosmetic purposes.

Uses—Expressed oil of almond is used as an emollient and is an ingredient in several of official preparations (see page 1034).

OLEUM CHAULMOOGRÆ. U.S. Chaulmoogra Oil
[Ol. Chaulmoog.]

The fixed oil expressed from the seeds of *Taraktogenos Kurzii* King (Fam. *Flacourtiaceæ*). The fixed oil from the seeds of certain species of *Hydnocarpus*, when designated as such and when agreeing in physical and chemical characters with Chaulmoogra Oil, may be used in its place.

In addition to small quantities of the glycerides of the fatty acids commonly found in vegetable fats, chaulmoogra oil contains the glycerides of a series of highly unsaturated fatty acids, chiefly chaulmoogric acid, $C_{18}H_{32}O_2$, and hydnocarpic acid, $C_{16}H_{28}O_2$. This series of fatty acids differs from other ordinary fatty acids in being optically active and in possessing, as part of the molecular structure, a ring of carbon atoms. The therapeutic properties of chaulmoogra oil appear to be due to these optically active unsaturated fatty acids of the chaulmoogric series.

The sodium salts of the fatty acids of chaulmoogra oil and the ethyl esters prepared from these fatty acids have been introduced for hypodermic use in the treatment of leprosy with the claim that they are better tolerated than the oil. The ethyl esters prepared from the fatty acids of the oil have been used for a number of years.

Description and Physical Properties—A yellow or brownish-yellow liquid, or, at temperatures below about 25° C., a whitish, soft solid. It has a characteristic odor, and a somewhat acrid taste.

Chaulmoogra Oil is sparingly soluble in alcohol; soluble in benzene, chloroform, ether, and in petroleum benzin.

Tests for Identity—Specific gravity: about 0.950 at 25° C.

The specific rotation $[\alpha]_D$ of Chaulmoogra Oil determined at 25° C. in chloroform, containing about 10 Gm. of the Oil in each 100 cc. of the solution, and using a 100 mm. tube, is not less than +48° and not more than +60°, page 1524.

Tests for Purity—Dissolve 1 Gm. of the Oil in 15 cc. of a mixture of equal volumes of alcohol and ether, previously neutralized with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, and titrate the solution with tenth-normal sodium hydroxide to the production of a pink color which persists for fifteen seconds: not less than 1.8 cc. and not more than 5 cc. of tenth-normal sodium hydroxide is required (*free acid*).

Saponification value: not less than 196 and not more than 213, page 1519.

Iodine value: not less than 98 and not more than 104, page 1519.

Preserve in well-closed containers, in a cool place, protected from light.

Uses—Chaulmoogra oil has been used in the treatment of leprosy for many years, much of the evidence indicating that it is of value, though not having specific, curative properties. The fatty acids of chaulmoogra oil, which are official under the title Æthylis Chaulmoogras, page 921, have a destructive action on acid-fast bacilli, such as the bacillus of leprosy, and it is to this property that the beneficial effects of chaulmoogra oil derivatives in leprosy are probably due. Chaulmoogra oil is given by mouth or by hypodermic injection, although the latter procedure is not devoid of disadvantages (abscesses).

Dose—By mouth, 0.3 cc. (5 drops) in capsules thrice daily, increasing to the point of tolerance. By hypodermic injection it has been used mixed with olive oil, the following being a typical formula: chaulmoogra oil, 500 cc.; olive oil, 500 cc.; camphor, 5 Gm.; guaiacol, 10 Gm.

Such mixtures are given by intramuscular injection in doses of from 2 to 10 cc. once a week.

OLEUM OLIVÆ. U.S. Olive Oil

[Ol. Oliv.]

The fixed oil obtained from the ripe fruit of *Olea europœa* Linné (Fam. *Oleaceæ*).

Preparation—It is obtained by crushing the recently collected ripe olives in a mill without breaking the putamen, then moderately pressing the pulpy mass. This produces the highest grade oil, known as *virgin oil.* The mass in the press is then mixed with water and again expressed with greater pressure, an oil of second quality resulting. Any oil remaining in the press cake is finally extracted with carbon disulphide, or the mass is thrown into large cisterns, mixed with water, and the oil allowed to separate. A few years ago it was difficult to obtain pure olive oil, but since the passage of the Food and Drugs Act it is unusual to find original packages labeled "olive oil" which do not contain genuine olive oil. When bought in bulk or from unlabeled containers, cottonseed oil or other bland oils are not uncommonly found as adulterants. Large quantities of olive oil are imported from Italy and other countries bordering the Mediterranean, and it is produced to a limited extent in the Southern United States, chiefly in California.

Description and Physical Properties—A pale yellow, or light greenish-yellow, oily liquid, having a slight, peculiar odor and taste, with a faintly acrid after-taste.

Olive Oil is slightly soluble in alcohol, but is miscible with ether, chloroform, and carbon disulphide.

Tests for Identity and Purity—Specific gravity: 0.910 to 0.915 at 25° C.

When cooled to from 10° to 8° C., the Oil becomes somewhat cloudy from the separation of crystalline particles, and at 0° C. it usually forms a whitish, granular mass.

Mix 5 cc. of the Oil in a test tube with 5 cc. of a mixture of equal volumes of amyl alcohol and carbon disulphide, the latter containing 1 per cent of precipitated sulphur in solution, and immerse the test tube to one-third of its depth in boiling, saturated aqueous solution of sodium chloride: no reddish color develops in fifteen minutes (*cottonseed oil*).

Mix 2 cc. of the Oil with 1 cc. of hydrochloric acid containing 1 per cent of sucrose, shake the mixture for half a minute, and allow it to stand for five minutes: on adding 3 cc. of distilled water to the mixture and shaking it, the acid layer shows no pink color (*sesame oil*).

Saponify 10 Gm. of Olive Oil by heating it under a reflux condenser with a solution of 4 Gm. of potassium hydroxide in 80 cc. of alcohol for one hour. Neutralize exactly with diluted acetic acid, using phenolphthalein T.S. as indicator, and wash into 120 cc. of boiling lead acetate T.S. Boil the mixture for one minute, and cool by immersing the flask in cold water, occasionally rotating the contents to cause the precipitate to adhere to the sides of the flask. Decant the liquid, wash the precipitate with cold water to remove excess of lead acetate, then wash with 90 per cent alcohol (by volume). Add 100 cc. of ether, cork well, and allow to stand until the precipitate is disintegrated. Connect with a reflux condenser, boil for five minutes, cool to about 15° C., and allow to stand overnight. Filter, and thoroughly wash the precipitate of lead soaps with ether. Wash the precipitate into a 500 cc. separator by means of a jet of ether, alternating with diluted hydrochloric acid at the end if a little of the precipitate adheres to the filter paper. Add enough diluted hydrochloric acid to make the total acid layer about 100 cc., and enough ether to make the total ether layer about 100 cc., and shake vigorously for several minutes. Allow the layers to separate, draw off the acid layer, and wash the ether once by shaking with 50 cc. of diluted hydrochloric acid and then with several portions of water until the water washings are no longer acid to methyl orange T.S. Transfer the ether solution to a dry flask, evaporate the ether, add a little dehydrated alcohol and evaporate on a steam bath. Dissolve the dry fatty acids by warming with 50 cc. of 90 per cent alcohol (by volume), slowly cool the solution to 15° C., shaking frequently to aid crystallization, and allow the mixture to stand at 15° C. for thirty minutes. No crystals separate (*peanut oil*).

Saponification value: not less than 190 and not more than 195, page 1519.

Iodine value: not less than 79 and not more than 90, page 1519.

Preserve in well-closed containers, in a cool place.

U.S.P. Preparation—Emplastrum Plumbi Oleatis.

N.F. Preparations—Curatio Paraffini; Emplastrum Fuscum Camphoratum; Linimentum Calaminæ; Oleatum Veratrinæ; Oleum Phenolatum; Unguentum Fuscum.

Uses—Olive oil is used in making cerates, ointments, liniments, and plasters. It is a bland, agreeable oil, well suited for emollient purposes and for food.

Average dose—1 fluidounce (30 cc.).

OLEUM GOSSYPII SEMINIS. U.S. Cottonseed Oil

[Ol. Gossyp. Sem.—Cotton Seed Oil]

The refined, fixed oil obtained from the seeds of cultivated varieties of *Gossypium herbaceum*, Linné or of other species of *Gossypium* (Fam. *Malvaceæ*).

Preparation—This oil is made commercially in the southern part of the United States upon a very large scale. The seeds contain about 15 per cent of oil.

The testa of the seeds is first separated, and the kernels are exposed to powerful expression in hydraulic presses. The crude oil thus obtained requires purification before it is suitable for medicinal or food purposes.

Description and Physical Properties—A pale yellow, oily liquid. It is odorless or nearly odorless, and has a bland taste.

Cottonseed Oil is slightly soluble in alcohol, but is miscible with ether, chloroform, petroleum benzin, and with carbon disulphide.

Tests for Identity and Purity—Specific gravity: 0.915 to 0.921 at 25° C.

At a temperature below 12° C. particles of solid fat separate from the Oil, and at about 0° to −5° it becomes solid or nearly so.

Dilute cottonseed Oil with an equal volume of carbon disulphide, and add sulphuric acid (specific gravity 1.6 to 1.7): a reddish-brown color is rapidly produced.

Mix 2 cc. of the Oil in a test tube with 2 cc. of a mixture of equal volumes of amyl alcohol and a 1 per cent solution of precipitated sulphur in carbon disulphide, and immerse the test tube to one-third of its depth in a boiling, saturated aqueous solution of sodium chloride: a red color develops in from ten to fifteen minutes.

Saponification value: not less than 190 and not more than 198, page 1519.

Iodine value: not less than 105 and not more than 114, page 1519.

Preserve in well-closed containers.

U.S.P. Preparation—Linimentum Camphoræ.

N.F. Preparations—Ampullæ Camphoræ; Unguentum Picis Compositum.

Uses—The official preparations are given above. It is sometimes given internally in the dose of four fluidrachms (16 cc.).

OLEUM LINI. U.S. Linseed Oil

[Ol. Lini—Oil of Flaxseed, Raw Linseed Oil]

The fixed oil obtained from linseed. Linseed Oil which has been "boiled" must not be used or dispensed.

Preparation—The Pharmacopœia excludes oil which has been boiled, the objection to this arising from the fact that *"boiled oil"* is intended for use in paints and varnishes, and compounds of lead or manganese are usually added to increase the drying property. The presence of any foreign substance renders the oil unfit for medicinal use. "Raw oil" should be ordered.

Linseed oil is a drying oil, and consists mainly of *linolein*, which, by exposure, becomes *linoxyn*, $C_{32}H_{54}O_{11}$; *myristin* and *palmitin* are also present.

Description and Physical Properties—A yellow, oily liquid, having a peculiar odor, and a bland taste. When exposed to the air, it gradually thickens, darkens in color, and acquires a more pronounced odor and taste.

Linseed Oil is slightly soluble in alcohol, but is miscible with ether, chloroform, petroleum benzin, carbon disulphide, and with oil of turpentine.

Tests for Identity and Purity—Specific gravity: 0.925 to 0.935 at 25° C.

Linseed Oil, when spread in a thin layer on a glass plate and allowed to stand in a warm place, is gradually converted into a hard, transparent film (*non-drying oils*).

Dissolve 2 Gm. of Linseed Oil in 20 cc. of a mixture of equal volumes of alcohol and ether, which has previously been neutralized with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, and titrate with tenth-normal sodium hydroxide to the production of a pink color, which persists for fifteen seconds: not more than 1.5 cc. of tenth-normal sodium hydroxide is required (*free acid*).

To 10 cc. of the Oil, add 3 Gm. of potassium hydroxide, 10 cc. of alcohol, and 10 cc. of distilled water, and heat the mixture on a water bath with frequent agitation until a clear solution results: the addition of 100 cc. of distilled water to this solution yields a clear liquid, free from oily drops (*mineral or rosin oils*).

Warm 2 cc. of the Oil with an equal volume of glacial acetic acid in a test tube, agitating frequently, and after cooling add to the mixture 1 drop of sulphuric acid: a greenish color is produced (a violet color under these circumstances indicates the presence of *rosin or rosin oils*).

Unsaponifiable matter: not more than 1.5 per cent, page 1520.

Saponification value: not less than 187 and not more than 195, page 1519.

Iodine value: not less than 170, page 1519.

Preserve in well-stoppered containers.

U. S. P. Preparations—Linimentum Calcis; Liquor Cresolis Compositus; Sapo Mollis.

N. F. Preparations—Ceratum Resinæ Compositum; Pasta Zinci Mollis; Petroxolinum Sulphuratum; Petroxolinum Sulphuratum Compositum.

Uses—Linseed oil is occasionally used as a laxative, in doses of one to two fluidounces (30 to 60 cc.), and in the official preparations named above.

PEPO. U. S. Pepo

[Pumpkin Seed]

Pepo is the dried ripe seed of cultivated varieties of *Cucurbita Pepo* Linné (Fam. *Cucurbitaceæ*).

Pepo contains not more than 5 per cent of broken or defective seed or other foreign organic matter.

Description—Broadly-ovate, flat; from 15 to 23 mm. in length and from 2 to 3 mm. in thickness; white or whitish, nearly smooth, with a shallow groove parallel to the edge; containing a short, conical radicle and two flat cotyledons; inodorous; taste bland and oily.

For further description see the U. S. P. X.

Uses—This seed contains about 40 per cent of fixed oil, starch, protein compounds, a little acrid resin, sugar, etc. Pumpkin seed is used as a tænifuge in the form of an *emulsion*. This may be prepared by blanching 2 oz. (av.) of the seeds, by soaking them in hot water, then beating them to a mass with 240 grains of sugar and 60 grains of acacia, and gradually adding 4 fluidounces of water. A better method, however, is to emulsify the fixed oil, which is now an article of commerce, and made by percolating the ground seeds with ether. Dose, of the seed, one ounce (30 Gm.).

OLEUM MORRHUÆ. U. S. Cod Liver Oil

For description, tests and assay see page 1187.

OLEUM RICINI. U. S. Castor Oil

[Ol. Ricin.]

The fixed oil obtained from the seeds of *Ricinus communis* Linné (Fam. *Euphorbiaceæ*).

Preparation—Castor oil is prepared by cold expression and subsequent clarification of the oil by heat. It contains *ricinolein* and palmitin. The purgative action is supposed to be due to the presence of two principles *ricin*, an unorganized ferment related to the toxalbumins and *ricinine*, $C_8H_8N_2O_2$, a poisonous base, precipitated from solution by mercuric chloride solution and Wagner's reagent. Other alkaloidal reagents do not affect it. A given weight of the seeds is more active than the same quantity of oil.

Description and Physical Properties—A pale yellowish or almost colorless, transparent, viscid liquid. It has a faint, mild odor, and a bland, afterwards slightly acrid and usually nauseating taste.

Castor Oil is miscible with dehydrated alcohol and with glacial acetic acid.

Tests for Identity and Purity—Specific gravity: 0.945 to 0.965 at 25°C.

Castor Oil is only partly soluble in petroleum benzin (*difference from most other fixed oils*), but it yields a clear liquid with an equal volume of alcohol (*foreign fixed oils*).

Dissolve 2 Gm. of Castor Oil in 20 cc. of alcohol, which previously has been neutralized with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, and titrate

with tenth-normal sodium hydroxide to the production of a pink color which persists for fifteen seconds: not more than 1.5 cc. of tenth-normal sodium hydroxide is required (*free acid*).

Saponification value: not less than 179 and not more than 185, page 1519.

Iodine value: not less than 83 and not more than 88, page 1519.

Preserve in well-closed containers.

U. S. P. Preparation—Collodium Flexile.

N. F. Preparations—Emulsum Olei Ricini; Oleum Ricini Aromaticum.

History—The *Palma Christi* tree as the castor oil plant was called has been identified as Jonah's Gourd. It is certain that the seeds of this plant and the oil pressed therefrom were used by the ancient Egyptians and are referred to in the Ebers Papyrus.

The name *Ricinus* was the Latin name of the dog-tick and was applied to these seeds on account of their resemblance in appearance to the insect. In Greek the same insect was known as *Kroton*. The name castor oil was derived through an erroneous belief during the sixteenth and seventeenth centuries that the plant which yielded the seeds was *Agnus Castus*.

Uses—Castor oil is used as a purgative, in doses of one-half to one fluid-ounce (15 to 30 cc.).

The administration of castor oil is greatly facilitated by adding the dose, extemporaneously, to a small amount of "soda water" flavored with "sarsaparilla" syrup, as much foam being developed as possible by using a fine stream. The glass should be well wetted with water and the oil carefully poured into the center of the glass without touching the side

It may also be administered in capsules or by mixing it with an equal bulk of aromatic syrup of rhubarb and shaking thoroughly before administering.

It is also administered to children in the form of a jelly, made by adding 3 per cent of spermaceti and a suitable flavor, such as oil of peppermint or made up by the following formula:

Castor Oil Jelly

Castor Oil	3 fl. oz., 21	min.
Stearic Acid	38	gr.
Sodium Hydroxide (U. S. P.)	9	gr.
Saccharin	1½	gr.
Oil of Peppermint	3	min.
Alcohol	81	min.

Dissolve the sodium hydroxide in the alcohol, add the castor oil and stearic acid, heat until combined, add the other ingredients and then cool.

OLEUM TIGLII. U. S. Croton Oil

[Ol. Tiglii]

The fixed oil expressed from the seeds of *Croton Tiglium* Linné (Fam. *Euphorbiaceæ*).

Caution—Croton Oil must be handled with caution as it causes pustular eruptions when applied to the skin. It should never be sold except on a physician's order.

Preparation—Croton oil is prepared by expression or by percolating the ground seeds with carbon disulphide and distilling the percolate. Neither the purgative principle nor the vesicating principle has been isolated; by the decomposition of the fatty substances present, tiglinic, valeric, formic, acetic, myristic, stearic, isobutyric, lauric, and palmitic acids have been detected; *croton-resin*, $C_{13}H_{18}O_4$, is said to be present.

Description and Physical Properties—A pale yellow or brownish-yellow, somewhat viscid and slightly fluorescent liquid, having a slight, characteristic odor.

Croton Oil is slightly soluble in alcohol, the solubility increasing with age; freely soluble in ether, chloroform, and in fixed or volatile oils.

Tests for Identity and Purity—When gently heated with twice its volume of dehydrated alcohol, it forms a clear solution from which the Croton Oil separates, either partially or completely, on cooling.

It is acid to litmus paper, previously moistened with alcohol.

Specific gravity: 0.935 to 0.950 at 25° C.

Add 1 cc. of fuming nitric acid and 1 cc. of distilled water to 2 cc. of the Oil and shake the mixture vigorously for a few minutes: it does not solidify either completely or partially after standing for twenty-four hours (*foreign oils*).

Saponification value: not less than 200 and not more than 215, page 1519.

Iodine value: not less than 104 and not more than 110, page 1519.

Preserve in small, well-stoppered bottles, protected from light.

Uses—Internally in doses of one minim (0.06 cc.), croton oil is a powerful purgative; externally, when applied to the skin, it is rubefacient and vesicant.

The collodion and liniment of croton oil of the N. F. IV have been omitted (see pages 344 and 350).

OLEUM THEOBROMATIS. U. S. Oil of Theobroma

[Ol. Theobrom.—Cacao Butter, Cocoa Butter]

The fat obtained from the roasted seeds of *Theobroma Cacao* Linné (Fam. *Sterculiaceæ*).

Preparation—This is made by grinding the kernels of the "chocolate bean" and expressing in powerful, horizontal hydraulic presses. The yield is about 40 per cent. It has also been prepared by dissolving the oil from the unroasted beans by the use of a volatile solvent. This oil, however, is not official in the U. S. P.

Chemically it is a mixture of stearin, palmitin, olein, arachin, and laurin, and, owing to its low fusing point, and its property of becoming solid at a temperature just below the fusing point, it is valuable in pharmacy for making suppositories. (See Suppositoria.)

Description and Physical Properties—A yellowish-white solid, having a faint, agreeable odor, and a bland, chocolate-like taste.

It is usually brittle at temperatures below 25° C.

Oil of Theobroma is slightly soluble in alcohol; soluble in boiling dehydrated alcohol; freely soluble in ether, chloroform, petroleum benzin, and in benzene.

Tests for Identity and Purity—Specific gravity: about 0.973 at 25° C.

It melts between 30° and 35° C.

Refractive index: 1.4537 to 1.4578 at 40° C., page 1525.

Dissolve 1 Gm. of Oil of Theobroma in 3 cc. of ether in a test tube at a temperature of 17° C., and immerse the tube in water having the temperature of melting ice: the liquid does not become turbid or deposit white flakes in less than three minutes. After congealing, raise the temperature to 15° C.: a clear liquid is gradually formed (*wax, stearin, or tallow*).

Saponification value: not less than 188 and not more than 195, page 1519.

Iodine value: not less than 33 and not more than 38, page 1519.

Uses—In addition to its use as a vehicle for suppositories cacao butter is an excellent emollient application to the skin when inflamed; it also is used in various skin creams especially the so-called "*skin foods*". It is also used in massage.

ADEPS. U. S. Lard

The purified internal fat of the abdomen of the hog *Sus scrofa* var. *domesticus* Gray (Fam. *Suidæ*).

Preparation—The adipose matter adhering to the kidneys, mesentery, and omentum of the hog is the usual source of the best lard. This, after careful removal of the membranes and adhering flesh, should be cut into small pieces, malaxated with successive portions of cold water until this remains clear, and then heated moderately, in a tinned iron or copper vessel, over a slow fire, until the melted fat becomes perfectly clear and anhydrous. This operation is known as *rendering*. Lastly, it is to be strained into earthen pots,

being occasionally stirred as it cools; the pots should be securely covered with waxed or varnished paper, or the lard protected from the air by pouring over it a thin layer of melted paraffin, and kept in a cool, dry cellar.

Description and Physical Properties—A soft, white, unctuous mass, having a faint odor, and a bland taste. It is free from rancidity.

Lard is insoluble in water; very slightly soluble in alcohol; readily soluble in ether, chloroform, carbon disulphide, and in petroleum benzin.

Tests for Purity—Lard melts between 36° and 42° C., forming a clear liquid from which no aqueous layer separates.

Distilled water boiled with lard shows no alkaline reaction to litmus paper (*alkalies*).

Dissolve 10 Gm. of Lard in 30 cc. of chloroform, mix the solution with 10 cc. of neutralized alcohol, and add one drop of phenolphthalein T.S.: not more than 2 cc. of tenth-normal sodium hydroxide is required to produce a pink tint when shaken vigorously (*free fatty acids*).

Boil 1 Gm. of Lard with 20 cc. of alcohol under a reflux condenser for ten minutes, cool, filter, and add to the filtrate 5 drops of an alcoholic solution of silver nitrate (1 in 50): the turbidity, if any, is not greater than that produced by the same quantity of the silver nitrate solution in a mixture of the same volume of alcohol and 0.5 cc. of fiftieth-normal hydrochloric acid (*chloride*).

Agitate in a test tube 5 cc. of melted and filtered Lard, while warm, with 5 cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 cc. of alcohol, and adding 2 drops of nitric acid), and heat this mixture for five minutes on a water bath: the liquid fat acquires no reddish or brown color, nor is any dark color produced at the line of contact of the hot liquids (*cottonseed fats*).

Dissolve 5 Gm. of Lard in 20 cc. of ether, in a test tube, close the tube loosely with purified cotton, and allow it to stand for about eighteen hours at a temperature of about 20° C. Collect some of the crystals which have separated at the bottom of the test tube, mount them either in alcohol or in a fixed oil, and examine under a microscope having a magnifying power of about two hundred diameters; lard stearin crystallizes in the form of flat, rhomboidal plates, cut off obliquely at one end and grouped irregularly. (Beef stearin crystallizes in the form of cylindrical rods or needles with sharp ends and grouped in fan-shaped clusters.)

Saponification value: not less than 195 and not more than 203, page 1519.

Iodine value: not less than 46 and not more than 70, page 1519.

Preserve in a cool place, in well-closed containers which are impervious to fat.

U. S. P. Preparations—Adeps Benzoinatus; Ceratum Resinæ; Emplastrum Plumbi Oleatis.

N. F. Preparations—Unguentum Camphoræ; Unguentum Hydrargyri Nitratis; Unguentum Picis Compositum; Unguentum Sinapis; Unguentum Sulphuris Compositum.

Lard, like most animal fat and oils, consists of stearin, palmitin, and olein; its consistence, when pure, depending largely upon the relative proportion of these principles; olein, being the liquid principle, can readily be separated from the other two by subjecting lard in cold weather to strong pressure, when the lard oil, consisting principally of olein is pressed out; the solid residue mainly consisting of stearin being used for various purposes, particularly for the manufacture of soap.

Lard Oil is a fixed oil, consisting principally of olein and made by exposing lard to a low temperature and then pressing it powerfully in an hydraulic press. Lard oil was formerly used in the official process for citrine ointment. Its principal uses are as a lubricant, especially in the wool industry, and as an illuminant.

Uses—Lard is used in pharmacy principally as a vehicle for ointments but it needs protection from rancidity. (See Adeps Benzoinatus.)

ADEPS BENZOINATUS. U.S. Benzoinated Lard

[Adeps Benz.]

	Metric	Alternative
Lard	1000 Gm.	16 oz. av.
Siam Benzoin, in coarse powder	10 Gm.	70 gr.
To make about	1000 Gm.	16 oz. av.

Melt the lard on a water bath, add the benzoin, mix thoroughly, and continue the heat for two hours, covering the vessel and not allowing the

temperature to rise above 60° C. Strain the liquid through muslin, and stir it occasionally while it cools.

Preserve in a cool place, in well-closed containers which are impervious to fat.

NOTE—For use in southern latitudes and during the heated season in other localities, 50 Gm. of the lard (or more, if necessary) may be replaced by an equal weight of white wax.

U. S. P. Preparations—Ceratum; Ceratum Cantharidis; Unguentum; Unguentum Hydrargyri Fortior; Unguentum Sulphuris.

N. F. Preparations—Ceratum Camphoræ; Mulla Acidi Salicylici; Mulla Creosoti Salicylata; Mulla Hydrargyri Chloridi Corrosivi; Mulla Zinci; Pasta Zinci Sulphurata; Unguentum Plumbi Iodidi; Unguentum Potassii Iodidi; Unguentum Stramonii; Unguentum Sulphuris Alkalinum; Unguentum Veratrinæ.

Certain balsamic substances, when digested with lard or fats, have the property of preventing or retarding rancidity; benzoin is most frequently used for this purpose. The temperature at which it is digested should not exceed 60° C., or the agreeable vanilla-like odor of the benzoin will be dissipated. A specially selected benzoin, called Siam benzoin or vanilla-benzoin is preferably used, and is now officially directed by the Pharmacopœia. The method of incorporating tincture of benzoin with cold lard does not produce a good product, for it is darker in color, less fragrant, and sometimes acts as an irritant when applied in certain skin diseases.

ADEPS LANÆ. U. S. Wool Fat

[**Adeps Lan.**—ANHYDROUS LANOLIN, REFINED WOOL FAT]

The purified, anhydrous, fat-like substance from the wool of sheep, *Ovis aries* Linné (Fam. *Bovidæ*).

Preparation—This substance, to which the name of *anhydrous lanolin* is applied is prepared by purifying the fatty matter obtained from the wool of the sheep (*suint*). This natural wool fat contains about 30 per cent of free fat acids and fatty acid esters of *cholesterol* and other higher alcohols. The cholesterol compounds are the important constituents and, to secure these in a purified form, many processes have been devised. In one of these the crude wool fat is treated with weak alkali, the saponified fats and emulsion centrifuged to secure the aqueous soap solution, from which, on standing, a layer of partially purified wool fat separates. This product is further purified by treating it with calcium chloride and then dehydrating by fusion with unslaked lime. It is finally extracted with acetone and the solvent subsequently separated by distillation. *Wool fat* differs from *hydrous wool fat* in containing practically no water. Wool fat consists mainly of *cholesterol* $C_{26}H_{43}OH.H_2O$ and *isocholesterol*, but other alcohols are present, associated with esters.

Description and Physical Properties—A brownish-yellow, tenacious, unctuous mass, having not more than a slight odor.

Wool fat is insoluble in water, but mixes without separation with about twice its weight of water. It is sparingly soluble in cold alcohol, more soluble in hot alcohol, and freely soluble in ether and in chloroform.

Tests for Identity and Purity—Wool Fat melts between 38° and 42° C.

Dried to constant weight on a water bath with frequent stirring, Wool Fat loses not more than 0.5 per cent of its weight (*water*).

Ash: not more than 0.1 per cent.

Dissolve 2 Gm. of Wool Fat in 10 cc. of ether, and add 2 drops of phenolphthalein T.S.: the liquid is not colored red (*free alkalies*), but on the addition of 0.2 cc. of tenth-normal sodium hydroxide a deep red color is produced (*free fatty acids*).

Boil 1 Gm. of Wool Fat with 20 cc. of alcohol under a reflux condenser, cool, filter, and add to the filtrate 5 drops of an alcoholic solution of silver nitrate (1 in 50): the turbidity, if any, is not greater than that produced by the same quantity of the silver nitrate solution in a mixture of the same volume of alcohol and 0.5 cc. of fiftieth-normal hydrochloric acid (*chloride*).

Warm 10 Gm. of Wool Fat with 50 cc. of distilled water on a water bath, constantly stirring the mixture until the Wool Fat is melted; the fat separates completely on cooling, leaving the

aqueous layer nearly clear and neutral to litmus paper. A 10 cc. portion of the filtered aqueous layer leaves no sweet residue on evaporation (*glycerin*). Another 10 cc. portion of the filtrate emits no *ammonia* vapors when boiled with 1 cc. of sodium hydroxide T.S., and a further 10 cc. portion does not completely decolorize 0.05 cc. of tenth-normal potassium permanganate within ten minutes (*soluble oxidizable impurities*).

About 0.5 Gm. of Wool Fat dissolves completely in 40 cc. of boiling dehydrated alcohol (*petrolatum*).

Iodine value: not less than 18 and not more than 28, using 0.8 to 0.85 Gm. of Wool Fat. page 1519.

Preserve in a cool place in well-closed containers which are impervious to fat.

U. S. P. Preparations—Unguentum Belladonnæ; Unguentum Iodi; Unguentum Iodoformi.

N. F. Preparations—Ceratum Plumbi Subacetatis; Unguentum Resorcinolis Compositum.

A proprietary ointment vehicle is sold under the trade name *Eucerin*. It is said to consist of 3 per cent of the free alcohols from wool fat, incorporated with petrolatum. The claim is made that this vehicle will not reduce metallic oxides but is capable of suspending large proportions of water.

Uses—Wool fat is used as a vehicle for ointments, but the hydrous wool fat is more frequently employed.

ADEPS LANÆ HYDROSUS. U. S. Hydrous Wool Fat

[Adeps Lan. Hyd.—LANOLIN]

Hydrous Wool Fat consists of wool fat incorporated with not less than 25 per cent and not more than 30 per cent of water.

Preparation—Hydrous wool fat is made by incorporating about 30 per cent of water with anhydrous wool fat.

Description and Physical Properties—A yellowish-white, or nearly white, ointment-like mass, having not more than a slight odor.

Hydrous Wool Fat is insoluble in water.

Tests for Purity—With ether and with chloroform Hydrous Wool Fat yields turbid solutions which are neutral to moistened litmus paper.

Hydrous Wool Fat heated on a water bath separates into an upper oily and a lower aqueous layer. When the heating is continued with frequent stirring until it ceases to lose weight, not less than 70 per cent and not more than 75 per cent of residue remains, which, when melted, is transparent and when cold, is a yellowish, tenacious, unctuous mass completely soluble in ether or chloroform and only sparingly soluble in alcohol. Hydrous Wool Fat thus deprived of water meets the requirements of the test for *petrolatum* under *Adeps Lanæ*.

Hydrous Wool Fat complies with the tests for *free alkalies, free fatty acids, chloride, glycerin,* and *ammonia,* described under *Adeps Lanæ*, allowance being made for the proportion of water present.

Preserve in a cool place, in well-closed containers which are impervious to fat.

U. S. P. Preparations—Unguentum Chrysarobini; Unguentum Hydrargyri Ammoniati; Unguentum Hydrargyri Oxidi Flavi.

N. F. Preparations—Inunctum Mentholis; Inunctum Mentholis Compositum; Petroxolinum Hydrargyri; Unguentum Hydrargyri Oxidi Rubri; Unguentum Stramonii.

Uses—This substance is used largely as a vehicle for ointments, for which it is admirably adapted, on account of the facility with which it is absorbed by the skin.

SEVUM PRÆPARATUM. U. S. Prepared Suet

[Sev. Præp.—MUTTON SUET]

The internal fat of the abdomen of the sheep *Ovis aries* Linné (Fam. *Bovidæ*) purified by melting and straining.

Preparation—Prepared Suet is made by a process similar to that for lard. (See Adeps.)

Description and Physical Properties—A white, solid fat, having, when fresh, a slight characteristic odor and a bland taste. It becomes rancid on prolonged exposure to the air and must not then be used.

Prepared Suet is insoluble in water and in cold alcohol. It is soluble in 45 parts of boiling alcohol, in about 60 parts of ether, and slowly dissolves in 2 parts of purified petroleum benzin. From its solution in the latter, when allowed to stand in a stoppered flask, it slowly separates in a crystalline form.

Tests for Identity and Purity—Prepared Suet melts between 45° and 50° C. and congeals between 37° and 40° C.

Saponification value: not less than 193 and not more than 200, page 1519.

Iodine value: not less than 33 and not more than 48, page 1519.

One Gm. of Prepared Suet, dissolved in 50 cc. of hot neutralized alcohol, with a few drops of phenolphthalein T.S. added, requires not more than 0.6 cc. of tenth-normal sodium hydroxide to produce a pink color (*free acid*).

Preserve in well-closed containers impervious to fat.

U. S. P. Preparation—Unguentum Hydrargyri Fortius.

N. F. Preparations—Ceratum Resinæ Compositum; Sevum Benzoinatum; Unguentum Fuscum.

Uses—Prepared suet is used in ointments and cerates and is firmer than lard, owing to its containing a larger proportion of stearin.

SEVUM BENZOINATUM. N. F. Benzoinated Suet

[Sev. Benz.]

	Metric	Alternative
Benzoin in moderately coarse powder	**30 Gm.**	210 gr.
Prepared Suet	**1000 Gm.**	16 oz. av.
To make about	**1000 Gm.**	16 oz. av.

Mix the benzoin thoroughly with the suet and allow the mixture to stand at the room temperature for two hours, then melt it on a water bath and maintain a temperature not exceeding 50° C., during one hour, stirring frequently; finally strain, and stir the mixture until cold.

OLEUM SESAMI. N. F. Sesame Oil

(U. S. P. IX)

[Ol. Sesam.—Teel Oil, Benne Oil]

A fixed oil obtained from the seeds of one or more cultivated varieties of *Sesamum indicum* Linné (Fam. *Pedaliaceæ*).

Preparation—It is obtained by subjecting benne seeds to pressure, the yield being about 50 per cent. The best grade of oil is the cold pressed.

Official Description—A pale yellow, oily liquid.

Odor and Taste—Almost odorless and having a bland taste.

Solubility—Slightly soluble in alcohol, miscible with ether, chloroform, petroleum benzin, or carbon disulphide.

Specific gravity: 0.916 to 0.921 at 25° C. (77° F).

Tests for Identity and Purity—Shake 1 cc. of the Oil for half a minute with a solution of 0.1 Gm. of sugar in 10 cc. of hydrochloric acid; the acid layer becomes bright red and changes to dark red on standing.

Free Acid—Blue litmus paper previously moistened with alcohol is not more than slightly reddened by 2 cc. of the Oil.

Cottonseed Oil—Mix 5 cc. of the Oil in a test tube with 5 cc. of a mixture of equal volumes of amyl alcohol and a 1 per cent solution of sulphur in carbon disulphide and immerse the test tube to one-third of its depth in a boiling saturated aqueous solution of sodium chloride; no reddish color develops in fifteen minutes.

Saponification value: not less than 188 and not more than 193.

Iodine value: not less than 103 and not more than 112.

N. F. Preparations—Linimentum Ammoniæ; Olea Infusa.

Uses—Used much like olive oil both medicinally and for food. It replaced cottonseed oil in ammonia liniment in the U. S. P. IX as it saponifies more readily and produces a more permanent and less sticky emulsion.

CACAO PRÆPARATUM. N. F. Cocoa

[Cacao Præp.—Prepared Cacao, Powdered Cocoa, or Cocoa Powder]

Cocoa is a powder prepared from the roasted, cured kernels of the ripe seed of *Theobroma Cacao* Linné (Fam. *Sterculiaceæ*). Cocoa powder is a by-product in the manufacture of oil of theobroma.

Official Description—A brownish powder.

Odor and Taste—A chocolate-like odor and taste, free from sweetness.

Tests for Identity and Purity—Extracted with ether, Cocoa yields not less than 18 per cent, or more than 25 per cent, of fat, and the fatty residue does not have a spicy odor or taste.

The residue insoluble in ether shows not more than 3 per cent of Cocoa shells.

Cocoa yields not more than 6 per cent of crude fiber and not more than 15 per cent of starch.

N. F. Preparations—Syrupus Cacao Præparati; Tabellæ Phenolphthaleini; Tabellæ Santonini; Tabellæ Santonini Compositæ.

Uses—It is used as a food and pharmaceutically as a flavor in tablets, syrups, pill coating, troches, etc.

LYCOPODIUM. U. S. Lycopodium

[Lycopod.]

Lycopodium consists of the spores of *Lycopodium clavatum* Linné (Fam. *Lycopodiaceæ*).

Official Description—A light yellow, very mobile powder. It is not wetted by water but floats upon it; when boiled with water it sinks; when thrown into a flame it burns with a quick flash. Nearly inodorous and tasteless. The spores of Lycopodium are spherical tetrahedrons, from 0.025 to 0.04 mm. in diameter.

For further description see the U. S. P. X.

Uses—Lycopodium contains 47 per cent of fixed oil, with minute quantities of volatile bases. It is used as a dusting powder for suppositories, and to allay irritation of the skin and for similar purposes.

Unofficial Fixed Oils

Oil of Bassia	From *Bassia longifolia*. Fam. Sapotaceæ. A greenish oil is expressed from the seeds
Bayberry	From *Myrica cerifera*. Fam. Myricaceæ. Habitat, North America. The oil and wax are prepared by boiling the fruit with water until the oil collects on the surface. The yield of oil is about 30 per cent
Beech	From the fruit of *Fagus sylvatica*. Fam. Cupuliferæ. Habitat, Europe. It is of a yellow color and mild odor and taste. The yield of oil is about 20 per cent
Behen	From the fruit of *Moringa aptera*. Used in ointments and pomades
Ben	A fixed oil from the seeds of *Moringa pterygosperma*. Used for the same purposes as olive oil
Black Mustard	From the seed of *Brassica nigra* (Linné) Koch. Fam. Cruciferæ. Habitat, Europe. A yellow or brownish-yellow fixed oil. Sp. gr. 0.916. The yield of oil is about 20 per cent
Brazil Nut	From the seed of *Bertholletia excelsa*. Fam. Lecythidaceæ. Habitat, Brazil. It is a pale yellow, bland oil. The yield of oil is about 50 per cent
Candle Nut	From *Aleurites triloba*. Habitat, islands of the Pacific Ocean. The yield of oil is about 60 per cent
Cardamom	From the fruit of *Elettaria repens*. Fam. Zingiberaceæ. The yield of oil is about 10 per cent
Cocoanut	From *Cocus nucifera*. Fam. Palmæ. Habitat, tropical countries. Prepared by boiling the seeds with water and expressing. It is of a butyraceous consistence, white, and has a peculiar odor and a bland taste.
Crab	From *Carapa guianensis*. Prepared by expressing the seed
Cucumber Seed	From the seed of *Cucumis sativus*. Fam. Cucurbitaceæ. Habitat, Central Asia
Ergot	From *Claviceps purpurea*. The yield of oil is about 25 per cent
Groundnut	From the kernels of the fruit of *Arachis hypogæa*. Prepared by expression
Hazelnut	From *Corylus avellena*. Fam. Cupuliferæ. Habitat, Europe. The yield of oil is about 50 per cent
Hemp Seed	From the seed of *Cannabis sativa*. Fam. Urticaceæ. Habitat, Europe and North America. The yield of oil is about 30 per cent
Horsechestnut	From the kernels of the fruit of *Æsculus hippocastanum*. Fam. Sapindaceæ. The yield of oil is about $\frac{1}{10}$ per cent
Hydrastis	From *Hydrastis canadensis*. Fam. Ranunculaceæ. Habitat, United States
Hyoscyamus Seed	From the seed of *Hyoscyamus niger*. Fam. Solanaceæ. Habitat, Europe. The yield of oil is about 25 per cent
Juglans	From *Juglans cinera*. Fam. Juglandaceæ. Habitat, United States. The yield of oil is about 15 per cent
Oil of Kurung	From *Pongamia glabra*. Fam. Leguminosæ. Habitat, India. It is a thickish, yellow oil, of sp. gr. 0.945
Larkspur Seed	From the seed of *Delphinium Consolida*. Fam. Ranunculaceæ. Habitat, Central Europe
Laurel	From *Laurus nobilis*. Fam. Lauraceæ. Habitat, Europe. Prepared by steeping the fruit in hot water and expressing
Mace	From the arillus of the fruit of *Myristica fragrans*. Fam. Myristicaceæ. Habitat, Molucca Islands
Madia	From *Madia sativa*. Fam. Compositæ. Habitat, Europe. The yield of oil is about 40 per cent

Unofficial Fixed Oils—*Continued*

Oil of Mangosteen	From *Garcinia indica*. Fam. Guttiferæ. Habitat, India. The yield of oil is about 30 per cent
Melon Seed	From *Cucumis Melo*. Fam. Cucurbitaceæ. Habitat, Central Asia
Nicker Seed	From *Cæsalpinia Bunducella*. Fam. Leguminosæ
Nigella	From the seed of *Nigella sativa*. Fam. Ranunculaceæ. Habitat, Southern Europe. The yield of oil is about 35 per cent
Niger Seed	From *Guizotia oleifera*. Fam. Compositæ. Habitat, India. The yield of oil is about 40 per cent
Nutmeg	From the kernel of the seed of *Myristica fragrans*. Fam. Myristicaceæ. Habitat, Molucca Islands. The yield of oil is about 22 per cent
Palm	From the fruit of *Elæis guineensis*. Fam. Palmæ. Habitat, West Africa. Sp. gr. 0.945
Peach	From *Persica vulgaris*. Fam. Rosaceæ. The oil resembles expressed oil of almond
Poppy Seed	From the seed of *Papaver somniferum*. Fam. Papaveraceæ. Habitat, Asia and Europe. It is of a yellow color, bland, and limpid. The yield is about 45 to 50 per cent
Pumpkin Seed	From the seed of *Cucurbita Pepo*. Fam. Cucurbitaceæ. Habitat, Asia and Europe. The yield of oil is about 45 per cent
Purging Nut	From the seed of *Curcas purgans*. Fam. Euphorbiaceæ. Habitat, West Indies. The yield is about 35 per cent
Rape Seed	From *Brassica campestris*. A fixed oil is used for making green soft soap
Staphisagria	From the seed of *Delphinium Staphisagria*. Fam. Ranunculaceæ. Habitat, Europe. The yield of oil is about 30 per cent
Stramonium Seed	From the seed of *Datura Stramonium*. Fam. Solanaceæ. Habitat, United States. The yield of oil is about 25 per cent
Tonka	From the seed of *Dipterix odorata*. Fam. Leguminosæ. Habitat, Guiana. An odorous fixed oil. The beans contain coumarin. Used for flavoring. Narcotic. Used in whooping-cough, in doses of five to eight grains (0.3 to 0.5 Gm.), given in the form of fluidextract
Tucom	From the fruit of *Astrocaryum vulgare*. Habitat, South America. It has a bright red color and an agreeable odor
Watermelon Seed	From the seed of *Cucurbita Citrullus*. Fam. Cucurbitaceæ. Habitat, Southern Asia. The yield is about 30 per cent
White Mustard	From the seed of *Sinapis Alba*. Fam. Cruciferæ. Habitat, Asia. The yield of oil is about 20 per cent

ACIDUM OLEICUM. U.S. Oleic Acid

[Acid. Oleic.]

Oleic Acid is obtained from fats, and consists chiefly of $C_{17}H_{33}COOH$ (282.36).

Preparation—Oleic acid is generally obtained as a by-product in the manufacture of candles from fats, the solid stearic and palmitic acids being the fatty substances sought for by candle manufacturers. The crude oleic acid is known as "red oil", the stearic and palmitic acids being separated by cooling the mixture and filtering.

Description and Physical Properties—A pale yellow or brownish-yellow, oily liquid. It has a peculiar lard-like odor and taste, but is free from disagreeable odor. On exposure to air it absorbs oxygen and becomes darker.

Oleic Acid is almost insoluble in water, but is miscible with alcohol, chloroform, ether, benzene, petroleum benzin, and with fixed or volatile oils.

Specific gravity: about 0.895 at 25° C.

On heating strongly, Oleic Acid is decomposed with the formation of acrid vapors.

Tests for Identity and Purity—When cooled to about 4° C., it congeals to a whitish solid or nearly solid mass.

The ash from 5 cc. does not exceed 0.005 Gm.

When gradually cooled, Oleic Acid does not become cloudy above 10° C. (*stearic acid*).

Shake 5 cc. of Oleic Acid with an equal volume of distilled water, allow the liquids to separate, and filter through a paper filter moistened with water: the filtrate is not reddened by the addition of a drop of methyl orange T.S. (*mineral acids*).

Boil 1 cc. of Oleic Acid with about 0.5 Gm. of sodium carbonate, and 30 cc. of distilled water in a capacious flask; the resulting solution, while hot, is clear or at most opalescent (*neutral fat or mineral oils*).

Preserve in well-closed glass or stoneware containers, in a cool place.

U.S.P. Preparation—Oleatum Hydrargyri.

N.F. Preparations—Oleatum Quininæ; Oleatum Veratrinæ; Pasta Zinci Mollis; in all Petroxolins; Unguentum Iodi Denigrescens.

Uses—Oleic acid is used as the basis for the oleates, a number of which are official (see page 350). The oleates are very useful external remedies; they are used in various skin diseases, and also for communicating the constitutional effects of numerous remedies. Oleic acid is more readily absorbed by the skin than any other similar vehicle.

Unofficial Oleates

Oleate of Aconitine (N. F. IV)	Prepared by dissolving 2 Gm. of Aconitine in 5 Gm. of oleic acid and adding olive oil to make 100 Gm.
Oleate of Atropine (N. F. IV)	Triturate 2 Gm. of Atropine with 2 cc. of alcohol in a tared mortar, adding 2 cc. of oleic acid and warm until alcohol evaporates. Then add oleic acid to make 50 Gm. and triturate until dissolved. Finally, add olive oil to make 100 Gm.
Oleate of Cocaine (N. F. IV)	Triturate 5 Gm. of cocaine with 5 cc. of alcohol in a tared mortar, adding 2 cc. of oleic acid and warm until alcohol evaporates. Then add oleic acid to make 50 Gm. and triturate until dissolved. Finally add olive oil to make 100 Gm.
Aluminum Oleate, $Al(C_{18}H_{33}O_2)_3$	By decomposing sodium oleate with aluminum sulphate. It is a semi-solid, of a dark brown color, and has a decidedly astringent action. Used in treating burns, scalds, foul ulcers, etc.
Silver Oleate, $AgC_{18}H_{33}O_2$	By precipitating sodium oleate with a saturated solution of silver nitrate, washing the precipitate with boiling water, drying it, and reducing to a fine powder. It is of a brownish-yellow color. Used externally
Arsenic Oleate, $As(C_{18}H_{33}O_2)_3$	By first preparing arsenous chloride by treating metallic arsenic with hydrochloric acid, and then adding sodium oleate and collecting the precipitate. It is of a yellowish color and has the consistence of butter
Bismuth Oleate, $Bi(C_{18}H_{33}O_2)_3$	By dissolving *crystallized* bismuth nitrate in glycerin, then diluting sodium oleate with water and adding the bismuth solution to the sodium mixture, warming, rejecting the aqueous layer, and lastly, washing several times with warm water. It is of a white or a yellowish-white color, and has about the consistence of an ointment
Copper Oleate, $Cu(C_{18}H_{33}O_2)_2$	By adding sodium oleate to a saturated solution of copper sulphate, then washing the precipitate. It is a handsome, dark green, waxy solid. Used chiefly in the treatment for ringworm
Iron Oleate (Ferric), $Fe(C_{18}H_{33}O_2)_3$	By adding sodium oleate to a solution of ferrous sulphate and boiling. It is a dark red, soft, solid oleate. Used locally
Manganese Oleate	By adding to a solution of sodium oleate a solution of manganese sulphate, heating gently, and collecting the precipitate. It is of a light gray, slightly pinkish color, having a peculiar odor
Mercury and Morphine Oleate	By combining with a gentle heat 40 parts mercuric oleate, 3 parts morphine, and 13 parts oleic acid. It forms a very dark brown, soft solid
Nickel Oleate	By adding sodium oleate to a solution of nickel sulphate and collecting the precipitate. It is a green, amorphous, waxy substance. Used locally as an astringent
Sodium Oleate	By dissolving 1 part of pure Castile soap in 8 parts of hot water, cooling and filtering from deposited sodium palmitate. The filtrate contains sodium oleate
Sodium Oleate, Acid, $NaC_{18}H_{33}O_2$	Contains an excess of oleic acid. Yellow, fatty granules. Used in biliary lithiasis
Tin Oleate	By adding a solution of tin chloride to a solution of sodium oleate and collecting the precipitate. It has a grayish-yellow color, a soft consistence, and a decided metallic taste

ACIDUM STEARICUM. U.S. Stearic Acid

[Acid. Stear.]

Stearic Acid is obtained from tallow and other solid fats, and consists chiefly of $C_{17}H_{35}.COOH$ (284.38).

Preparation—It is usually prepared from tallow and similar fats by boiling them with soda lye, separating the glycerin and decomposing the resulting soap with sulphuric or hydrochloric acid. The stearic acid is subsequently separated from any oleic acid by cold expression. It is also prepared by the hydrogenation of olein (see page 1033). It may be purified by dissolving in hot alcohol when, upon cooling, the acid separates.

Description and Physical Properties—A hard, white or faintly-yellowish, somewhat glossy and crystalline solid. It is odorless, or has a slight, tallow-like odor, and is stable in the air.

Stearic Acid is almost insoluble in water. One Gm. dissolves in 21 cc. of alcohol, 2 cc. of chloroform, and in 3 cc. of ether, at 25° C. It is soluble in carbon disulphide and in carbon tetrachloride.

Tests for Purity—Melting point: not below 56° C.

Congealing point: not below 54° C.

Ash: not more than 0.1 per cent.

Boil 1 Gm. of Stearic Acid and 0.5 Gm. of sodium carbonate with 30 cc. of distilled water in a capacious flask: the resulting solution while hot is not more than opalescent (*neutral fat or paraffin*).

Shake melted Stearic Acid with an equal volume of hot distilled water, cool, and filter: the filtrate is not reddened by the addition of a drop of methyl orange T.S. (*mineral acids*).

U.S.P. Preparation—Suppositoria Glycerini.

N.F. Preparation—Linimentum Saponato-Camphoratum.

Uses—Its chief use in pharmacy is in the preparation of sodium stearate which is the solidifying agent for the official glycerin suppositories, and for many other commercial products, such as toilet creams, solidified alcohol (see page 95), solidified smelling salts, etc.

GLYCERINUM. U.S. Glycerin

[Glycerin.—Glycerol]

Glycerin contains not less than 95 per cent of $CH_2OH.CHOH.CH_2OH$ (92.08).

Preparation—This valuable liquid has been made in several ways: 1. Through the saponification of fats and oils in making soap or lead plaster. 2. By the decomposition of fats and oils through pressure and superheated steam. 3. It has also been prepared synthetically, one method being the heating of trichlorpropane with water, at a temperature of 180° C. During the World War vast quantities of glycerin were made in Germany by the fermentation of beet sugar molasses in the presence of large amounts of sodium sulphite. Under these conditions the following reaction takes place:

$$\underset{\text{glucose}}{C_6H_{12}O_6} = \underset{\text{glycerin}}{C_3H_5(OH)_3} + \underset{\text{acetaldehyde}}{CH_3CHO} + \underset{\text{carbon dioxide}}{CO_2}$$

Glycerin came into use in medicine and pharmacy about 1846, and it was first obtained on a commercial scale from the washings of lead plaster by Robert Shoemaker, of Philadelphia. In making the plaster, litharge, olive oil, and water are boiled together, when the olein of the oil is decomposed by the lead oxide, according to the following equation:

$$\underset{\text{glyceryl oleate (olive oil)}}{2C_3H_5(C_{18}H_{33}O_2)_3} + \underset{\text{lead oxide}}{3PbO} + \underset{\text{water}}{3H_2O} = \underset{\text{lead oleate (lead plaster)}}{3Pb(C_{18}H_{33}O_2)_2} + \underset{\text{glyceryl hydroxide (glycerin)}}{2C_3H_5(OH)_3}$$

The process most frequently used for making glycerin originated with R. A. Tilghman, of Philadelphia, and consists in subjecting fatty bodies to the action of water at a high temperature under pressure, whereby the fats, which are *glycerides* or esters of the fatty acids, are broken up into glycerin and fatty acids, the water supplying the elements of hydrogen and oxygen necessary to the change. The reaction is expressed as follows in the case of a fat like stearin:

$$\underset{\text{stearin}}{C_3H_5(C_{18}H_{35}O_2)_3} + \underset{\text{water}}{3H_2O} = \underset{\text{glycerin}}{C_3H_5(OH)_3} + \underset{\text{stearic acid}}{3HC_{18}H_{35}O_2}$$

Chemically, glycerin belongs to the class of alcohols, and is sometimes termed *glycerol*, or *glyceric alcohol*. It is the hydroxide of the radical glyceryl, C_3H_5, which is trihydric, and one, two, or three of the hydroxyl groups may be replaced by monad radicals.

Description and Physical Properties—A clear, colorless, syrupy liquid, having a sweet taste It has not more than a slight, characteristic odor, which is neither harsh nor disagreeable. When exposed to the air, it absorbs moisture.

Glycerin is miscible with water and with alcohol. It is insoluble in chloroform, ether, benzene, petroleum benzin, carbon disulphide, and in fixed or volatile oils.

Tests for Identity—Heat a few drops of Glycerin with about 0.5 Gm. of potassium bisulphate: pungent vapors of acrolein are evolved.

Tests for Purity—Glycerin is colorless when viewed transversely in a tube of colorless glass about 30 mm. in diameter, held in a vertical position.

Specific gravity: not below 1.249 at 25° C.

An aqueous solution of Glycerin (1 in 20) is neutral to litmus paper.

Heat 50 Gm. of Glycerin in an open, shallow, 100 cc. porcelain dish until it ignites, and allow it to burn without further application of heat in a place free from draught: not more than 0.015 per cent of carbonaceous and mineral residue remains. Ignite this residue at a low red heat, until combustion is complete: not more than 0.007 per cent of mineral residue remains.

Place 5 cc. of Glycerin in a 50 cc. glass-stoppered cylinder, add 5 cc. of sulphuric acid, and shake vigorously for one minute: the liquid does not become darker than yellow on standing for one hour (*readily carbonizable substances*).

Mix 50 Gm. of Glycerin with 50 cc. of freshly boiled distilled water and 5 cc. of half-normal sodium hydroxide, boil the mixture for five minutes, cool, and titrate the excess of alkali with

half-normal hydrochloric acid, using phenolphthalein T.S. as indicator: not less than 4 cc. of half-normal hydrochloric acid is required (*fatty acids and esters*).

Ten cc. portions of an aqueous solution of Glycerin (1 in 10) remain clear on the addition of 0.5 cc. of calcium chloride T.S. (*oxalate*), or of 0.5 cc. of silver nitrate T.S. (*chloride*), and no turbidity is produced in 10 cc. of the solution, previously treated with three drops of diluted hydrochloric acid, by the addition of five drops of barium chloride T.S. (*sulphate*).

An aqueous solution of Glycerin meets the requirements of the test for *heavy metals*, page 1519, and of the test for *arsenic*, page 1512.

A mixture of 5 cc. of Glycerin and 5 cc. of an aqueous solution of potassium hydroxide (1 in 10) does not become yellow when kept for five minutes at 60° C. (*acrolein, glucose*) or emit an odor of ammonia (*ammonium compounds*).

Preserve in well-closed containers.

U. S. P. Preparations—Gelatinum Glycerinatum; Glycerites; Fluidextracts; Liquor Ferri et Ammonii Acetatis; Massa Hydrargyri; Mistura Cretæ; Mistura Glycyrrhizæ Composita; Mucilago Tragacanthæ; Pilulæ Ferri Carbonatis; Pilulæ Phosphori; Sapo Mollis; Suppositoria Glycerini; Syrupus Ipecacuanhæ; Syrupus Pruni Virginianæ; Tinctures; Unguentum Acidi Tannici; Unguentum Iodi.

N. F. Preparations—Cataplasma Kaolini; Elixirs; Glycerites; Fluidextracts; Fluidglycerates; Mixtures; Liquors; Syrups; Tinctures, etc.; Lotio Calaminæ; Mel Rosæ et Sodii Boratis; Mel Sodii Boratis: Pasta Dextrinata; Suppositoria Boroglycerini; Unguentum Resorcinolis Compositum.

Uses—Glycerin is one of the most valuable products known to pharmacy. It is solvent and antiseptic, scarcely inferior to alcohol. Glycerin is useful in keeping substances moist, owing to its tendency to absorb water from the air. It is a valuable emollient in many skin diseases, and its agreeable taste and nonpoisonous properties adapt it for many purposes. Its varied pharmaceutical uses have been frequently referred to in the preceding pages.

When glycerin is acted on by nitric acid, nitroglycerin, a powerful explosive, is formed. This is used in the preparation of dynamite and other high explosives; it is sometimes called *glonoin* and *trinitrin*. A 1 per cent alcoholic solution is official (see Spiritus Glycerylis Nitratis, page 310).

Soaps

Soaps are salts of metals combined with fatty acids. Soaps may be divided into two classes, *soluble* and *insoluble*. The soluble soaps are the detergent or cleansing soaps and are compounds of the fatty acids with the alkali metals, sodium and potassium particularly. Sapo and sapo mollis are examples of soluble soaps. The insoluble soaps are salts of the fatty acids and metals of any other group. Lead oleate plaster is an example of an insoluble soap in the pure state, zinc stearate is another, while lime liniment owes its characteristic properties to a calcium soap of linseed oil.

Soaps may also be divided into hard and soft soaps. The hard soaps are those in which sodium is the base and the soft soaps are those in which potassium is used. The predominance of olein or stearin respectively has some influence upon the consistence of soaps.

Soap may be made in several ways as follows:

1. Saponification of fats or oils by alkalies, the resulting glycerin being removed from the soap and sold as a by-product.
2. Saponification of fats or oils by alkalies, the resulting glycerin being allowed to remain in the finished soap.
3. Direct neutralization of free fatty acids by alkali hydroxides or carbonates, no glycerin being produced.

The reaction involved in the first and second processes is illustrated by the following equation:

$$\underset{\substack{\text{fixed oil or fat}}}{C_3H_5(\text{oleo-palmito stearate})} + \underset{\text{caustic alkali}}{3NaOH} = \underset{\text{soap}}{3Na(\text{oleo-palmito stearate})} + \underset{\text{glycerin}}{C_3H_5(OH)_3}$$

The reaction occurring in the third process is shown by the following equation:

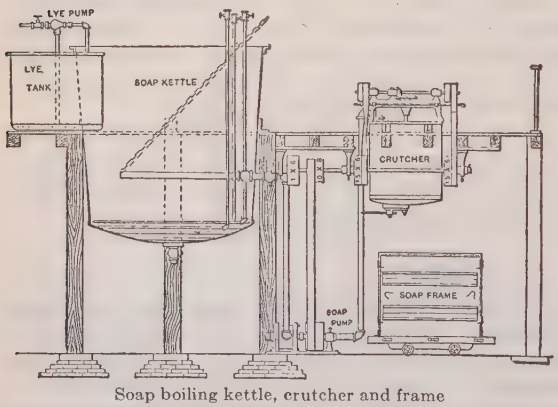
$$\underset{\text{stearic acid}}{HC_{18}H_{35}O_2} + \underset{\text{caustic alkali}}{NaOH} = \underset{\substack{\text{sodium stearate, a very}\\\text{hard variety of soap}}}{NaC_{18}H_{35}O_2} + \underset{\text{water}}{H_2O}$$

The quality of the soap in a measure depends upon the completeness of the saponification and the care taken to produce a neutral or almost neutral soap.

For certain purposes, such as for exceptional detergent or germicidal value, as in "soft soap", to be used for cleansing the hands of a surgeon and in preparing an area for a surgical operation, a slight excess of alkali is desirable, but for toilet purposes and for the laundry the neutrality of the soap is essential. A few soaps are superfatted, that is, they contain an excess of fat but they are only used for special purposes, such as to remove an excess of machine oil or some such form of dirt.

Another characteristic of the fatty acid influences the solubilities of soaps and thus has a bearing upon their adaptability. All soaps except those made from cocoanut oil are insoluble in salt (sodium chloride) solutions and therefore only cocoanut oil or chiefly cocoanut oil must form the basis for what is known as "marine soap" to be used with sea water. This quality of soaps is taken advantage of in their manufacture to separate the glycerin, salt being added to the saponified mixture, causing it to rise to the top of the soap-boiling kettles (see Fig. 437) in more or less granular form, leaving the glycerin, "spent lye", and salt solution at the bottom to be drawn off and treated for the glycerin. This stage of the process is known as "graining". When the glycerin has been removed, the separated soap is again heated and water is added to restore a uniform consistence. This warm mixture is then drawn off into mixers, known technically as "crutchers" (see Fig. 437), where, if the soap is a cheap laundry or washing soap, an inexpensive perfume may be incorporated, and a better consistence secured by actively stirring before the soap is run into "frames" to cool. If the soap is to be a "floating" soap, the "crutching" or beating is continued until sufficient air has been worked into the cooling mass to make the specific gravity less than that of water.

FIG. 437



Soap boiling kettle, crutcher and frame
(From "Modern Soaps, Candles, and Glycerin" by L. L. Lamborn)

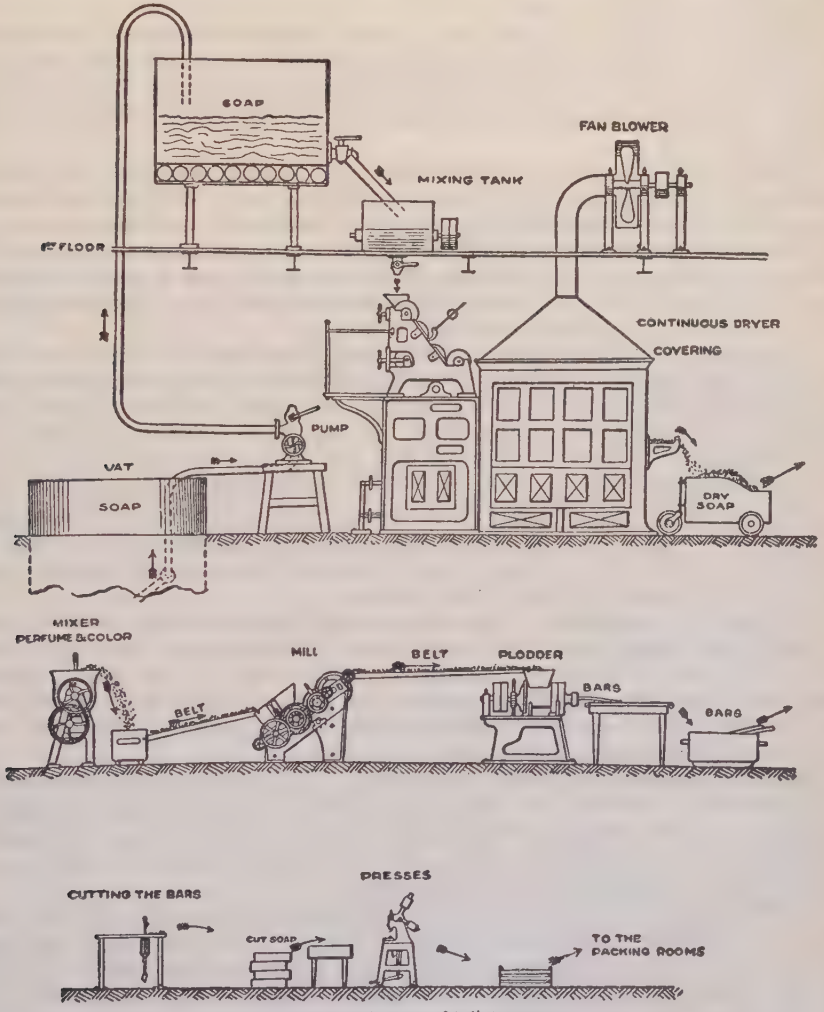
A "floating soap", therefore, means less soap for the size of the cake and thousands of minute air spaces throughout the cake, which tend to increase its solubility and wasting qualities.

The "frame" (see Fig. 437) into which the soap is run to cool usually consists of an iron or steel box about 4½ feet long, 15 inches wide, and 4 feet deep, mounted on wheels. The sides and ends are removable and each frame holds about 1000 pounds of soap. When the soap in the frame has cooled sufficiently, the sides are removed and in due time the mass of soap is cut into slabs by forcing it against piano wires fitted to a frame, and these slabs in turn are

cut in the same manner into bars weighing about three pounds each. In the cheaper laundry soaps these bars are further cut into cakes, and the cakes roughly stamped by a press, before being wrapped and boxed.

Much laundry soap is now being sold in powder and flake form. This not only enables the user to regulate the exact amount of soap used but also

FIG. 438



The manufacture of toilet soap
(From "Modern Soaps, Candles, and Glycerin" by L. L. Lamborn)

provides quick solution and is admirably adapted to the modern domestic or laundry washing machines. In the production of chip soap it is not necessary to run the warm fluid soaps into frames to cool as the crutched soap, while still fluid, is run between a series of cooled steel rollers and the thin film which dries on the rollers is mechanically scraped off at one stage of the process. It then drops to a movable belt and is carried into a warm closet, from which it emerges dry enough to market as "flake" or "chip" soap (see Fig. 438).

For the production of powdered soap, the flakes are more thoroughly dried and are then powdered in the usual manner.

It must be evident to all who know something of the nature of soap that an important factor in its actual value is the percentage of water it contains. Not only does this control the amount of soap available, but when a large amount of water is present a soap in cake form rapidly disintegrates when used and fails to give adequate service.

It may be startling information to some to know that often as much as 80 per cent of laundry soap in cakes is represented by water. In flakes the water must be greatly reduced and is not often above 5 per cent. This is another reason for the preference of chip or flake soap over other forms, for laundry purposes.

Washing powders, on the other hand, are usually mixtures, rarely containing more than 20 per cent of soap and often less. In addition to the soap they usually contain from 25 to 30 per cent of "soda ash" (sodium carbonate), the remainder being water. This combination of soap and "soda ash" is particularly efficient in the washing of clothes and, even if pure chip soap is used, the experts who conduct experiments in laundry methods advise the addition of soda ash to the first water.

To produce the higher grade toilet or medicinal soaps, the bars cut from the frames are reduced to chips by a chipping machine or scraped directly from the roller (see Fig. 438). These are further dried and then "milled" (see Fig. 438) by passing them repeatedly through heavy rollers without heat, until a uniform mass results. During this process the coloring matter, if any, is incorporated and also the desired perfume or medicating ingredients.

This soft mass is then forced under heavy pressure into bars of the shape and size best suited to form the desired cake, the machine being called a "plodder" (see Fig. 438). These bars, while yet soft from the milling, are then cut into cake size and stamped into tablets.

The raw fatty materials from which commercial soaps are made depend to some extent upon the market conditions. The cheapest form of olein or stearin obtainable is likely to be employed as the basis for the soap. Among these ingredients are bone fat, cocoanut oil, palm kernel oil, palm oil, olive oil, "olive oil foots", peanut oil, cottonseed oil, corn oil, soya bean oil, linseed oil, hydrogenated oils, rosin, tallow, and fatty acids.

Kinds of Commercial Soaps—*Curd Soap*—Curd soap is a soap separated by salt solution, reheated and mixed with sufficient water to form a smooth emulsion, run into frames, cooled, and cut into bars or cakes. It usually constitutes the bar laundry soap. It is frequently high in alkali and usually contains fillers, such as sodium silicate.

Mottled Soap—This is a form of curd soap, showing streaks of color irregularly running through the mass. Formerly it was caused by the addition of some metallic salt, as ferrous sulphate, manganese dioxide, or ultramarine. Originally such soaps were considered to be of superior quality, but the effects have been artificially produced, so that today mottled soap does not necessarily indicate a high grade soap, often containing as little as 20 per cent of actual fatty acid. The mottled soaps have nearly disappeared from the American market.

Milled Soap—When a high-grade soap stock has been made by the boiling or the cold process, and dried in the frames, it is then cut into slabs and bars and subsequently chipped. These chips in turn are milled between stone rollers until the soap has acquired a uniform consistence. Such soap is much more lasting when finally made into cakes and may be variously colored

or perfumed. It is possible, of course, to apply this general process to low-class soaps, but whatever the basic stock, a milled soap is much more serviceable and satisfactory than the same soap cut directly from the bars.

Soft Soap—This soap, made from potash, or mixtures of potash and soda, and usually a liquid fat, has already been referred to. It is chiefly used medicinally, either as a cleanser for the hands of the surgeon or for preparing an operating area or in the treatment of the skin or scalp. It is most frequently employed in alcoholic solution under the name "tincture of green soap".

Disinfectant Soap—If some form of disinfectant, such as cresol or phenol, is added to soap stock during the milling, the soap is known as a disinfectant soap, even though the amount of added substance is not sufficient to produce very effective germicidal action.

Marine Soap and Hard Water Soap—For use with sea water and also for use with water containing lime salts, known as "hard" water, ordinary soaps are very unsatisfactory, because such salts precipitate the soap. It is possible, however, to make a soap which is soluble and therefore usable in such water, by employing cocoanut oil as the fat and possibly introducing a small amount of palm kernel oil. It is this form of soap which is sold under the above names.

Transparent Soap—For many years there have been offered soaps which are known as "transparent" soaps. These were originally prepared chiefly from mixtures of cocoanut and castor oils and the resulting soap dissolved in alcohol. When the excess of alcohol is distilled off, the residue is transparent. It has been found possible in recent years to produce much cheaper and quite satisfactory transparent soaps from mixtures of cocoanut oil and castor oil by the simple addition of cane sugar syrup. Such soap has a tendency to "fig", that is, in time to separate crystalline salts of fatty acids.

Liquid Soap—A largely used form of soap, chiefly because of its economy and sanitary advantages, is known as "liquid soap". This is usually an aqueous solution of cocoanut oil-potash soap, suitably colored and perfumed. It is found in modern hotels and railroad trains and is used by means of a special apparatus which delivers a few drops of the soap without contaminating the remainder.

Floating Soap—Floating soap is made by beating the soap in a crutcher soon after running it from the boiling kettles. Air is thus beaten into the soap as it cools and the resulting production is thus made lighter than water. While this lessens the actual weight of soap in a cake it is justified by adding to the convenience in the use of the product.

Shaving Soap—Soaps for use in shaving are usually made from carefully selected stock and are carefully neutralized to avoid any caustic action when applied to the face. These soaps generally contain a large percentage of cocoanut oil. Tragacanth and milk sugar are added in small amounts to shaving creams to increase the permanence of the lather.

Grit Soap—For cleaning the hands, when especially soiled with grease or machine work, soaps are offered which contain powdered silica mixed with the soap. Such soaps are on the market in paste and cake form.

Dry-Cleaning Soap—Cleansers of this character usually consist of an ammonia or possibly a potash soap of oleic acid usually dissolved in a volatile solvent such as benzin. They are used to remove spots in clothing.

Scouring Powders—Substances of this character sold extensively in a box with a perforated top are not actually soaps. The makers usually claim freedom from alkali or caustic effect. They generally consist of powdered volcanic lava and serve in a purely mechanical function as a cleanser.

How Does Soap Clean?—Some believe that soap is used only as a lubricant. Through its use it becomes possible to easily rub the hands together or more readily scrub clothing or other surfaces and through its mechanical lubricant action the cleansing process is promoted. Another view of the reason why soap is efficacious is the fact that it usually hydrolizes when dissolved in water as may be readily shown by pouring an alcoholic solution of neutral soap into water. In a few moments the presence of free alkali due to hydrolysis becomes apparent if an indicator is added. Phenolphthalein will quickly turn pink, indicating free alkali. Many of the foreign substances on the hands and in clothing which are to be removed, are all of a fatty nature and it is argued that free alkali saponifies these and thus promotes cleanliness. But while these two explanations of the value of soap are doubtless true and they in part explain the value of soap, there is another quality which soap possesses, which is related to its colloidal character.

Soap possesses a quality which is known as "adsorption". When it comes in contact with foreign substances, it seems to possess the quality of combining and rendering soluble many otherwise insoluble materials. This quality may be very clearly illustrated by mixing lampblack with water and pouring the mixture on a filter. The water will pass through the filter leaving the black, greasy, lampblack on the interior surface. If some soap solution now is added to the mixture in the filter, the lampblack will be immediately carried through the filter, showing the peculiar effect of soap on otherwise insoluble substances. If salt is now added to the mixture in the filter, thus precipitating soap, the lampblack immediately regains its insoluble character and will not pass through the filter.

There are two kinds of soluble soaps official, *i. e.*, Olive Oil Castile Soap and Soft Soap. The official requirements are given below.

SAPO. U.S. Soap

[Olive Oil Castile Soap, White Castile Soap]

Soap prepared from olive oil and sodium hydroxide.

The official soap is commonly called Castile soap because it originally came from Castile, Spain. Much of the so-called Castile soap on the market is not pure olive oil soap but contains cocoanut oil soap to increase its lathering quality.

Description and Physical Properties—A white or whitish solid, in the form of bars, hard, yet easily cut when fresh, or a fine, yellowish-white powder. It has a faint, characteristic odor, free from rancidity, and a disagreeable, alkaline taste.

Soap is soluble in water and in alcohol, more readily, however, with the aid of heat.

An aqueous solution of Soap is alkaline to indicators.

Tests for Purity—Dissolve about 0.5 Gm. of Soap, accurately weighed, in 10 cc. of alcohol, evaporate the mixture to dryness in a tared beaker containing 1 Gm. of clean sand, which has been previously dried at 110° C., and dry the residue to constant weight at 100° C.: the loss does not exceed 36 per cent for unpowdered Soap or 10 per cent for powdered Soap (*water*).

A solution of a quantity of Soap corresponding to 0.64 Gm. of dried Soap in 25 cc. of hot alcohol does not gelatinize on cooling to 20° C. (*soap from animal fats*).

Ten cc. of an aqueous solution of Soap (1 in 20) remains unchanged in color upon the addition of ammonium sulphide T.S., and upon acidulating another portion of 10 cc. of the solution with hydrochloric acid and filtering, the filtrate remains unchanged in color when an equal volume of hydrogen sulphide T.S. is added and the mixture allowed to stand well-stoppered, in a warm place, for half an hour (*heavy metals*).

Dissolve about 10 Gm. of Soap, accurately weighed, in 100 cc. of neutralized alcohol, with the aid of heat. Transfer the undissolved residue, if any, to a tared filter which has been dried at 100° C., and wash it thoroughly with boiling neutralized alcohol. The weight of the residue after drying at 100° C. does not exceed 1 per cent of the weight of dry Soap taken (*sodium chloride, carbonate, silica, or other alcohol-insoluble substances*). This residue, thoroughly washed with distilled water and dried at 100° C., does not yield a residue exceeding 0.15 per cent of the weight of dry Soap taken (*silica or other water-insoluble substances*).

The alcoholic filtrate and washings from the preceding test are not reddened by 3 drops of phenolphthalein T.S. (*sodium hydroxide*).

Dissolve about 10 Gm. of Soap in 200 cc. of hot distilled water, add 2 drops of methyl orange T.S. and then diluted sulphuric acid with constant stirring until the aqueous layer becomes red. Boil the mixture until the supernatant layer of the fatty acids is clear and free from solid particles. Separate the aqueous layer with the aid of a siphon and wash the fatty acids by decantation with hot distilled water, until a 10 cc. portion of the washings, acidulated with a drop of hydrochloric acid, no longer gives a precipitate on the addition of barium chloride T.S. Place the dish containing the fatty acids on a water bath and heat until they are completely liquefied, filter the warm acids through a dry filter in a hot-water funnel into a flat dish, and dry over sulphuric acid. The iodine number of the acids thus obtained is not less than 84 and not more than 90, page 1519.

Preserve in well-closed containers.

U. S. P. Preparations—Extractum Colocynthidis Compositum; Linimentum Chloroformi (from Soap Liniment); Linimentum Saponis; Pilulæ Aloes; Pilulæ Asafœtidæ.

N. F. Preparations—Dentifricium; Emplastrum Saponis; Lavatio Ori, Pilulæ Aloes et Asafœtidæ; Pilulæ Rhei.

Uses—Soap is used in pill masses, in combination with resins, to render them soluble and to modify their harsh action. It is also used in liniments, plasters, cerates, etc.

SAPO MOLLIS. U. S. Soft Soap

[Sapo Moll.]

	Metric	Alternative
Linseed Oil	**400 Gm.**	14 oz. av. 48 gr.
Dekanormal Solution of Potassium Hydroxide	**29 cc.**	471 min.
Dekanormal Solution of Sodium Hydroxide	**110 cc.**	3 fl. oz. 345 min.
Glycerin	**50 cc.**	1 fl. oz. 332 min.
Water, a sufficient quantity, To make	**1000 Gm.**	35 oz. av. 120 gr.

Mix the dekanormal solutions, pages 1558 and 1561, with the oil and enough water to make the product weigh 925 Gm. [32 oz. av. 275 gr.]. Heat the mixture to boiling with frequent stirring, add the glycerin, and continue the boiling until the mixture becomes transparent and a portion dissolves completely in hot water, producing a clear solution. Then add sufficient hot water to make the Soap weigh 1000 Gm. [35 oz. av. 120 gr.] and allow to stand with little stirring until the water is absorbed.

NOTE—The 29 cc. [471 min.] of dekanormal solution of potassium hydroxide directed above may be replaced by 19.14 Gm. [295 gr.] of 85 per cent potassium hydroxide and the 110 cc. [3 fl. oz. 345 min.] of dekanormal solution of sodium hydroxide may be replaced by 48.89 Gm. [1 oz. av. 317 gr.] of 90 per cent sodium hydroxide, dissolving the hydroxides in 100 cc. (3 fl. oz. 183 min.) of water. If upon assay the potassium and the sodium hydroxides are found to be of any other strength, a proportionately larger or smaller quantity should be taken.

A variety of soft soap prepared from green colored oils, such as green olive oil, or artificially colored, is known as "Green Soap". The official soap is not green in color.

It has been demonstrated, moreover, that the green color adds nothing to the therapeutic value and cottonseed oil soap has long been used with satisfaction. On a large scale the soap may be prepared without the addition of alcohol or glycerin, heat and concentrated alkali producing saponification. "Green olive oil" has been used to make a green soap. It should contain a little free alkali, but an excess must be avoided; this is regulated by the U. S. P. test.

In the U. S. P. X linseed oil has again been introduced into soft soap because of its superior saponifying and detergent qualities. It has also been found possible to replace much of the potassium hydroxide by sodium hydroxide and still retain the soft character of the soap.

The dekanormal alkali solutions have been used in the official formula for the purpose of readily supplying a definite amount of alkali, the stick caustic being so deliquescent that the amount of water present is always indefinite. It is expected that the pharmacist will be able to buy these dekanormal solutions as he now buys strong acids. They have been shown to be relatively permanent if kept in stoppered bottles.

Description and Physical Properties—A soft, unctuous, yellowish-white to brownish-yellow mass, having a slight, characteristic odor and an alkaline taste.

An aqueous solution of Soft Soap is alkaline to litmus paper and phenolphthalein T.S.

Dissolve about 5 Gm. of Soft Soap, accurately weighed, in 100 cc. of hot neutralized alcohol, collect the residue, if any, on a filter, thoroughly wash it with hot neutralized alcohol, and dry it to constant weight at 100° C. The weight of the residue does not exceed 3 per cent of the weight of Soap taken. The combined filtrate and washings, on the addition of 0.5 cc. of phenolphthalein T.S. and titration with tenth-normal sulphuric acid, shows not less than 0.1 per cent and not more than 0.25 per cent of KOH. Each cc. of tenth-normal sulphuric acid corresponds to 0.00561 Gm. of KOH.

Tests for Purity—A solution of Soft Soap in hot distilled water (1 in 20) is nearly clear.

Soft Soap loses not more than 52 per cent in weight when tested for water as directed under *Sapo*.

U. S. P. Preparation—Linimentum Saponis Mollis.

N. F. Preparations—Linimentum Saponis Mollis Compositum; Pasta Betanaphtholis; Unguentum Sulphuris Compositum.

Uses—Green soap is used in skin diseases, chiefly in eczema, and largely as a detergent in surgery. It is also largely used in alcoholic solution, in the cleansing and treatment of the scalp.

Unsaponifiable Fats and Petroleum Products

Under this head will be found several official products which cannot be classed properly with either the fixed or the volatile oils, yet in some respects they partake of the properties of both. Petrolatum in its several forms, paraffin, and petroleum benzin, are products from petroleum, and are mixtures of hydrocarbons belonging to the methane series.

Crude Petroleum—Rock Oil

Petroleum has been known from the earliest historical period. Within the limits of the United States it has long been known to exist in a few localities. On the borders of Seneca Lake in the State of New York small quantities of it were collected, and to some extent used in medicine under the name of Seneca oil. In Western Pennsylvania, on Duck Creek in Ohio, near Scottsville in Kentucky, and on the Kanawha in Virginia, it attracted local attention, and a certain locality in Western Canada had acquired some notoriety by its burning spring. Little attention was paid to it until 1859, when, the preparation of oil for burning, distilled from bituminous shales, and called "coal oil", having proved profitable, and a strong resemblance having been shown to exist between this and petroleum, enterprise was directed towards some of the known resources of the latter liquid. The first oil well was sunk by Drake, in 1859, at Titusville, Pa., and from that arose an enormous industry. At first the most productive locality of petroleum was in Western Pennsylvania but it is now obtained in many States. After the Pennsylvania field, in order of development, is that of Ohio; but most of the oil produced in this state is from a different geological strata—*viz.*, the Trenton limestone—and contains a persistent sulphur impurity. This renders the Ohio oil (popularly known also as Lima oil, from the town of Lima, Ohio) more difficult and expensive to refine. It is hence very largely used in the crude state as fuel oil, and as such has been of the greatest industrial value, being shipped

by pipe line or tank cars to great distances. Within recent years large quantities of petroleum have been found in California, Texas, Louisiana, Kentucky, and Kansas, but in the main it is of a grade much inferior to that known as Pennsylvania oil, being largely used as fuel oil. Oil is also obtained from Mexico, and Russia, and is a big factor in international relations due to its great value.

Crude petroleum is occasionally almost colorless when taken from the earth, but is generally of a greenish color, appearing claret-red by transmitted light. The green color may, however, become so dark as to be almost black. In gravity, it varies from 0.865 to 0.777.

To purify petroleum the crude oil is run into large retorts of wrought iron and exposed to a heat rising gradually to between 315.5° C. whereby all the volatile ingredients are distilled, leaving from 5 to 10 per cent of solid residue, constituting a sort of coke. The liquids thus obtained are comparatively colorless, though still retaining the strong odor of the crude oil. The several fractions are collected separately, and show widely varying gravity and volatility, and are applied to different uses. An average result of a normal distillation may be stated as follows: Gasoline, 1½ per cent, refined naphtha 10 per cent, benzin 4 per cent, refined petroleum or kerosene (sometimes called coal oil) 55 per cent, lubricating oil 17½ per cent, paraffin 2 per cent, gas, and coke 10 per cent. As the greater demand for illuminating oil makes it desirable to get the maximum quantity of this fraction, the distillation is generally so conducted that by the process of "cracking" the yield of burning oil is increased at the expense of the lubricating oil and heavy naphtha. Many distilleries obtain, therefore, from 75 to 80 per cent of illuminating oil from the crude material.

Uses—Petroleum has been considered to be a stimulating antispasmodic, expectorant, and diaphoretic.¶ It was used as a folk remedy in the treatment of acute bronchitis, but probably with no beneficial action in this condition save by virtue of its nauseating effect. It is affirmed that many cases of asthma are much benefited by inhaling petroleum vapors. It is a minor ingredient in the popular remedy called British Oil. This is made as follows:

British Oil

Petroleum (Barbados)	1 fl. oz.
Petroleum (American)	1 fl. oz.
Oil of Turpentine	2 fl. oz.
Oil of Linseed	24 fl. oz.
Oil of Amber	8 fl. oz.
Oil of Juniper	2 fl. oz.

Mix them well together.

PETROLATUM LIQUIDUM. U. S. Liquid Petrolatum

[**Petrolat. Liq.**—Liquid Paraffin, White Mineral Oil, Paraffin Oil]

Liquid Petrolatum is a mixture of liquid hydrocarbons obtained from petroleum.

Preparation—After removing the lighter hydrocarbons from petroleum, by distillation, the residue is again subjected to distillation at a temperature between 330° and 390° C. and the distillate treated first with sulphuric acid, then with sodium hydroxide, and afterwards decolorized by filtering through bone black, animal charcoal, or fuller's earth. The purified product is again chilled, to remove paraffin, and redistilled at a temperature above 330° C. In some instances the sulphuric acid treatment is omitted.

Official Description—*Heavy Liquid Petrolatum*—Heavy liquid Petrolatum has a kinematic viscosity of not less than 0.381 at 37.8° C. (100° F), page 1526.

Light Liquid Petrolatum—Light Liquid Petrolatum has a kinematic viscosity of not more than 0.370 at 37.8° C. (100° F.), page 1526.

Each variety conforms to the following description and tests:

Description and Physical Properties—A colorless, transparent, oily liquid, free, or nearly free, from fluorescence.

It is insoluble in water and in alcohol; soluble in ether, chloroform, petroleum benzin, and in fixed or volatile oils. Camphor, menthol, thymol, and many similar substances are soluble in Liquid Petrolatum.

Tests for Purity—Specific gravity: 0.828 to 0.905 at 25° C.

Liquid Petrolatum is odorless and tasteless when cold, and develops not more than a faint petroleum odor when heated.

When cooled to 0° C., Liquid Petrolatum does not become more than opalescent (*solid paraffins*).

Boil 10 cc. of Liquid Petrolatum with an equal volume of alcohol: the alcohol remains neutral to moistened litmus paper (*acid or alkali*).

Pour 5 cc. of Liquid Petrolatum and 5 cc. of colorless sulphuric acid into a glass-stoppered cylinder, which has been previously rinsed with sulphuric acid, and heat in a water bath for ten minutes, shaking the mixture well at intervals of thirty seconds: the oil remains unchanged in color and the acid does not become darker than pale amber (*carbonizable substances*).

Prepare a saturated solution of lead monoxide in an aqueous solution of sodium hydroxide (1 in 5), and mix 2 drops of the clear solution with 4 cc. of Liquid Petrolatum and 2 cc. of dehydrated alcohol: the mixture does not darken after heating at 70° C. for ten minutes and cooling (*sulphur compounds*).

Preserve in well-closed containers, protected from light.

U. S. P. Preparations—Unguentum Hydrargyri Ammoniati; Unguentum Hydrargyri Oxidi Flavi.

N. F. Preparations—Nebula Aromatica; Nebula Eucalyptolis; Nebula Mentholis; Nebula Mentholis Composita; Nebula Thymolis; Pasta Resorcinolis Fortior; Pasta Resorcinolis Mitis; Petroxolins; Lubricant in Tabellæ.

Uses—Liquid Petrolatum is used as a basis for medicinal preparations, for spraying the nasal passages, and as a laxative, its efficiency being due to mechanical lubrication. For this latter purpose an oil of high viscosity, the so-called "heavy oil" is usually preferred as the lighter oils have a tendency to produce leakage. The lighter oils are used for spraying. Because of the widespread use of this oil as a laxative, it has been sold under many special names.

Average dose—4 fluidrachms (15 cc.).

A popular form of liquid petrolatum, for its laxative effect, is the *Agar emulsion.* Frequently the efficacy of this is increased by the addition of phenolphthalein, when it is called "*Compound Agar Emulsion of Petrolatum*".

This emulsion is usually prepared on the large scale in a special machine known as a homogenizer (see Emulsions), but it may be prepared by the pharmacist by the following formula, suggested by Ambrose Hunsberger:

Unofficial Agar Emulsion of Petrolatum (Plain)

Agar (pure granules or flakes)	68 gr.
Distilled Water	3½ pints

Boil this mixture for fifteen minutes, adding enough water to make up that lost by evaporation. Cool slightly, and strain if necessary. While still hot pour the above solution into a mixture of

Powdered Acacia	110 gr.
Powdered Tragacanth	110 gr.
Oil of Orange	3 fl. dr.
Liquid Petrolatum	4 pints

Shake the mixtures vigorously and repeat the shaking at frequent intervals until it becomes creamy and fully emulsified. Then cool and add the following solution:

Soluble Glucide	10 gr.
Compound Tincture of Vanilla	4 fl. dr.
Sodium Benzoate	2 dr.
Glycerin	4 fl. oz.
Water, sufficient to make 1 gallon.	

Shake well together or heat actively in an emulsion machine.

PETROLATUM. U.S. Petrolatum

[**Petrolat.**—Amber Petrolatum, Petroleum Jelly]

A purified, semi-solid mixture of hydrocarbons, obtained from petroleum.

Preparation—The "residuums", as they are termed technically, which are obtained by the distillation of petroleum, are purified by melting, usually

treating with sulphuric acid, and then percolating through recently burned bone black; this abstracts the odor and modifies the color.

Description and Physical Properties—An unctuous mass, varying in color from yellowish to light amber. It has not more than a slight fluorescence even after being melted, and is transparent in thin layers. It is free or nearly free from odor and taste.

Petrolatum is insoluble in water; almost insoluble in cold or hot alcohol, and in cold dehydrated alcohol. It is freely soluble in benzene, carbon disulphide, chloroform, and oil of turpentine. It is soluble in ether, petroleum benzin, and in most fixed or volatile oils, the degree of solubility in these solvents varying with the composition of the Petrolatum.

Tests for Identity and Purity—Specific gravity: 0.820 to 0.865 at 60° C.

It melts between 38° and 54° C.

Heat 2 Gm. of Petrolatum in an open porcelain or platinum dish over a Bunsen flame: it volatilizes without emitting an acrid odor, and on incineration leaves not more than 0.05 per cent of ash.

Shake melted Petrolatum with an equal volume of hot distilled water: the latter remains neutral to litmus paper (*acids or alkalies*).

Digest 10 Gm. of Petrolatum at 100° C., with 10 Gm. of sodium hydroxide and 50 cc. of distilled water for half an hour, then separate the aqueous layer, and supersaturate it with sulphuric acid: no oily or solid substance separates (*fixed oils, fats or rosin*).

U. S. P. Preparations—Unguentum Acidi Borici; Unguentum Belladonnæ; Unguentum Hydrargyri Mitis; Unguentum Hydrargyri Oxidi Flavi; Unguentum Iodoformi; Unguentum Phenolis; Unguentum Picis Pini.

N. F. Preparations—Emulsum Petrolati; Pasta Betanaphtholis; Pasta Zinci; Unguentum Hydrargyri Oxidi Rubri; Ointments.

Uses—Petrolatum is used as a basis for ointments, for which it is well adapted. It is, however, not so readily absorbed as are other unctuous bases. Special brands are known as *cosmoline*, *vascline*, *petrolina*, *deodorolina*, *albolene*, etc.

PETROLATUM ALBUM. U. S. White Petrolatum

[**Petrolat. Alb.**—White Petroleum Jelly]

Petrolatum wholly or nearly decolorized.

Preparation—It is prepared in the same manner as petrolatum, the charcoal treatment being continued until the product is practically free from yellow color. The product often sold for white petrolatum, made by mixing paraffin and liquid petrolatum, is not satisfactory for pharmaceutical purposes as it is granular and the liquid portion often separates. The U. S. P. test excludes this variety.

Description and Physical Properties—White Petrolatum is a white or faintly yellowish, unctuous mass, transparent in thin layers even after cooling to 0° C.

In other respects White Petrolatum has the characteristics of and responds to the tests for identity and purity under *Petrolatum*.

U. S. P. Preparations—Unguentum Hydrargyri Ammoniati; Unguentum Plumbi Oleatis; Unguentum Zinci Oxidi.

N. F. Preparations—Ceratum Camphoræ; Ceratum Plumbi Subacetatis; Curatio Paraffini; Unguentum Hydrargyri Chloridi Mitis; Unguentum Zinci Stearatis.

Uses—White petrolatum is employed as a basis for ointments and cerates.

PARAFFINUM. U. S. Paraffin

[**Paraff.**]

A purified mixture of solid hydrocarbons, obtained from petroleum.

Hard paraffin or *paraffin wax*, is a solid, white, diaphanous substance resembling white wax, which is made by distilling the residuum obtained from the refining of petroleum and collecting and purifying the distillate. It can be mixed in all proportions with wax, stearin, palmitin, and rosin, but it is difficult to prevent the mixtures from "granulating", even after prolonged stirring.

Description and Physical Properties—A colorless, or white, more or less translucent mass, frequently showing a crystalline structure. It is without odor or taste, and is slightly greasy to the touch.

Paraffin is insoluble in water and in alcohol; slightly soluble in dehydrated alcohol; freely soluble in chloroform ether, benzene, petroleum, benzin, carbon disulphide, volatile oils, and in most warm fixed oils.

Tests for Identity and Purity—Specific gravity: about 0.900 at 25° C.

It melts between 50° and 57° C.

For further tests see the U. S. P. X.

U. S. P. Preparations—Paraffinum Chlorinatum; Unguentum Zinci Oxidi.

N. F. Preparations—Curatio Paraffini; Unguentum Capsici; Unguentum Iodi Denigrescens.

Uses—It is used in denarcotizing tincture of opium, also as the basis for burn dressings (see Curatio Paraffini, below) and in addition it is used to increase the consistence of some ointments.

PARAFFINUM CHLORINATUM. U. S. Chlorinated Paraffin

[**Paraff. Chlorinat.**—Chlorcosane]

A chlorinated paraffin.

Description and Physical Properties—A light yellow to light amber, clear, thick, oily liquid. It is odorless and is stable in the air.

Chlorinated Paraffin is insoluble in water; slightly soluble in alcohol, but miscible with benzene, carbon tetrachloride, chloroform, and with ether.

Tests for Identity and Purity—See the U. S. P. X.

CURATIO PARAFFINI. N. F. Paraffin Dressing

[**Curat. Paraf.**]

A formula for the largely used paraffin dressing for burns has been made official in the N. F. V. Paraffin intended for application to burns, etc., should be solid at body temperature, but more ductile and pliable than the official paraffin. It should be liquid at or below 50° C. A thin film when prepared and tested as described below should be pliable at or below 28° C. and ductile at or below 31° C. At body temperature (38° C.) it should be pliable, and adhere to, but permit ready detachment from, the skin.

	Metric	Alternative
Resorcinol	**1 Gm.**	17½ gr.
Oil of Eucalyptus	**2 cc.**	35 min.
Olive Oil	**3 cc.**	52 min.
White Petrolatum	**12 Gm.**	210 gr.
Paraffin	**82 Gm.**	3 oz. av. 123 gr
To make	**100 Gm.**	4 oz. av.

Melt the paraffin, add the white petrolatum and olive oil, and stir, continuing the heat if necessary, until a uniform liquid is obtained. Dissolve the resorcinol in the oil of eucalyptus, add to the warm paraffin mixture and mix well. Stir the mixture frequently until it begins to congeal.

Uses—Paraffin for films acts mechanically. When applied to burns and denuded surfaces, it provides an air-excluding dressing which relieves pain, forming a soft, pliable splint-like covering to wounded surfaces, keeps the parts at a relatively uniform temperature, immobilizes the epidermal tissue, and may aid in the formation of new tissue by acting as a scaffolding for newly-formed cells.

Paraffin for films is used mainly in the treatment of burns. It is said to be useful in the treatment of frostbite and chilblains, and for covering denuded surfaces. It is also employed to prepare paraffin covered bandages and to seal gauze dressings.

In the paraffin treatment of burns, the wound, after preparatory treatment, is dried and a thin coating of the melted paraffin dressing (at a temperature of about 53° C.) is applied by means of an atomizer or brush. This is followed by the application of a thin layer of cotton and then another layer of the melted paraffin. The dressing is finished by covering with cotton and bandaging.

A simple and equally efficient method consists in cutting a thin sheet of cotton or similar absorbent to a size somewhat larger than the wound. This is dipped into the melted paraffin, applied snugly to the wound, and covered with a bandage.

Similar preparations have been sold under trade names such as *Ambrene* and *Parresine*.

BENZINUM PURIFICATUM. U. S. Purified Petroleum Benzin

[**Benzin. Purif.**—Petroleum Ether]

Purified Petroleum Benzin is a purified distillate from American petroleum, consisting of hydrocarbons, chiefly of the methane series.

The U. S. P. VIII method of purification was as follows:

	Metric	Alternative
Potassium Permanganate	10 Gm.	146 gr.
Sodium Hydroxide	2 Gm.	29 gr.
Sulphuric Acid	60 cc.	2 fl. oz.
Petroleum Benzin	1000 cc.	2 pints
Water, a sufficient quantity.		

Add the acid to 550 cc. [17½ fl. oz.] of water, and when the mixture has become cold, pour it into a bottle having a capacity of about two liters [4 pints]. Add 8 Gm. [117 gr.] of potassium permanganate and agitate until it is dissolved, then add the petroleum benzin, in four portions, shaking the liquor after each addition. Allow the liquids to remain in contact for 24 hours, shaking the bottle at frequent intervals; then decant the petroleum benzin into another bottle of the same capacity, and having dissolved 2 Gm. [29 gr.] of potassium permanganate in 240 cc. [8 fl. oz.] of water, in which the sodium hydroxide has previously been dissolved, mix the liquids and agitate the mixture frequently during several hours, then decant, repeat the washing with water, and again decant the purified petroleum benzin.

Description and Physical Properties—A clear, colorless, non-fluorescent, volatile liquid, having an ethereal or faint, petroleum-like odor, and a neutral reaction.

Caution—It is highly inflammable, and its vapor, when mixed with air and ignited, explodes violently.

Purified Petroleum Benzin is practically insoluble in water. It is freely soluble in alcohol, and is miscible with ether, chloroform, benzene, and with fixed or volatile oils, with the exception of castor oil.

Tests for Identity and Purity—Specific gravity: 0.634 to 0.660 at 25° C.

Purified Petroleum Benzin distils completely between 35° and 80° C., when determined by Method II, page 121.

Pour 10 cc. of Purified Petroleum Benzin in portions upon clean, odorless filter paper laid on a warm glass plate. No disagreeable or notably sulphureted odor becomes apparent as the last portions disappear from the paper, and no greasy stain remains.

Not more than 0.001 Gm. of residue remains on evaporating 50 cc. of Purified Petroleum Benzin at a temperature not exceeding 40° C.

For further tests see the U. S. P. X.

Preserve in well-closed containers, in a cool place, remote from fire.

U. S. P. Preparations—Extractum Colchici; Extractum Nucis Vomicæ; Fluidextractum Colchici; Tinctura Digitalis; Tinctura Strophanthi.

Uses—Petroleum benzin is a useful solvent for fats, resins, oils, caoutchouc, and similar bodies. It is not identical with benzene, the product obtained in the destructive distillation of coal. The object of introducing purified petroleum benzin into the Pharmacopœia was to furnish a solvent which would not communicate a disagreeable odor to preparations, as is the case when commercial petroleum benzin is used.

Petroleum Benzin and similar solvents of like origin such as gasoline are frequently used in so-called "*dry cleaning*" which is a term used to describe cleaning garments etc., without the use of water. Their efficiency in this direction is due to the facility with which they remove grease spots, and with them the adherent dirt. The use of inflammable solvents for such purposes, either on the large or small scale is always attended with more or less danger. Carbon tetrachloride, which is a non-inflammable solvent used for similar purposes, may be used as an ingredient for mixing with petroleum distillates to reduce their inflammability and at the same time augment their grease dissolving powers. Seventy-five per cent of carbon tetrachloride and twenty-five per cent of petroleum benzin makes a non-inflammable mixture which is an excellent solvent for grease, and may be used with perfect safety.

Unoffiical Petroleum Products

Kerosene, Deodorized, N. N. R.	Kerosene treated to remove odorous constituents. Used, because of its solvent action on fats, as a pediculocide and as a means of removing dandruff and the detritus of wounds. Employed also as a vehicle in sprays and liniments

CHAPTER LXXII

DRUGS CONTAINING GLUCOSIDES OR NEUTRAL PRINCIPLES, WITH THEIR PREPARATIONS

THE glucosides are organic plant principles of complex constitution. Under the recent system of international chemical nomenclature they belong to the group which includes the carbohydrates proper and which general group is distinguished by the name *"glucides"*.

The distinguishing characteristic of the glucosides is the fact that upon decomposition they yield dextrose (formerly called glucose) with one or more substances, frequently of an aromatic nature.

They have been described as ester or ether-like compounds of carbohydrates with aromatic compounds. In the majority of cases the carbohydrate is dextrose, but it may be an isomeric hexose, as galactose, or a pentose such as rhamnose.

Examples of three types of glucosides are found in the following: *Salicin*, which upon decomposition yields *saligenin* and dextrose, as follows:

$$\underset{\text{salicin}}{C_{13}H_{18}O_7} + \underset{\text{water}}{H_2O} = \underset{\text{dextrose}}{C_6H_{12}O_6} + \underset{\text{saligenin}}{C_6H_4OHCH_2OH}$$

Digitonin which yields *digitogenin*, dextrose, and *galactose* as follows:

$$\underset{\text{digitonin}}{C_{54}H_{92}O_{28}} + \underset{\text{water}}{2H_2O} = \underset{\text{digitogenin}}{C_{30}H_{48}O_6} + \underset{\text{dextrose}}{2C_6H_{12}O_6} + \underset{\text{galactose}}{2C_6H_{12}O_6}$$

Quercitrin which yields *quercetin* and *rhamnose*, as indicated by the following equation:

$$\underset{\text{quercitrin}}{C_{21}H_{20}O_{11}} + \underset{\text{water}}{H_2O} = \underset{\text{quercetin}}{C_{15}H_{10}O_7} + \underset{\text{rhamnose}}{C_6H_{12}O_5}$$

The glucosides are devoid of nitrogen except in the case of a small group known as cyanogenetic glucosides, exemplified by amygdalin which splits up as follows:

$$\underset{\text{amygdalin}}{C_{20}H_{27}NO_{11}} + \underset{\text{water}}{2H_2O} = \underset{\text{dextrose}}{2C_6H_{12}O_6} + \underset{\text{benzaldehyde}}{C_6H_5CHO} + \underset{\text{hydrocyanic acid}}{HCN}$$

The reaction by which glucosides are split up into their constituent parts is a hydrolytic reaction. It may be brought about by boiling with dilute mineral acids or in some cases by alkalies. In the plants which contain glucosides the decomposition is effected by means of suitable ferments (such as *emulsin*, *myrosin*, etc.), which often exist in the same part of the plant, but usually in different cells from the glucosides.

Each glucoside may have an enzyme of a distinctive character associated with it, but the enzymes as a rule possess the power of splitting several glucosides.

There are no simple identifying tests for glucosides, except by the character of the cleavage products in some cases. Methods for the detection of glucosides and for their quantitative determination involve the estimation of reducing sugars before and after the solution is hydrolyzed by boiling with dilute acids, or by the action of emulsin.

The saponins are a group of glucosides, which are amorphous colloidal substances, readily soluble in water and producing a froth when the aqueous solution is agitated. They are excellent emulsifying agents and the aqueous solutions of some of them are used as detergents to replace soap (see quillaja).

Many of the saponins are markedly toxic in their physiological action. They usually possess a powerful solvent action on red blood corpuscles, a property known as hemolysis.

The saponins are widely distributed in the botanical kingdom.

Glucosides

Glucoside	Source	Derivatives
Adonidin	From *Adonis vernalis*	
Æsculin, $C_{15}H_{16}O_9$	From *Æsculus Hippocastanum*	Æsculetin
Amygdalin, $C_{20}NH_{27}O_{11}$	From *Prunus amygdalus*	Benzaldehyde and hydrocyanic acid
Arbutin, $C_{12}H_{16}O_7$, N. N. R.	From *Uva Ursi* and other Ericaceæ	Hydroquinone and methyl-hydroquinone
Bryonin, $C_{34}H_{48}O_9$	From *Bryonia alba* and *B. dioica*	Bryoretin and bryogenin
Colocynthin, $C_{56}H_{84}O_{23}$	From *Citrullus colocynthis*	Colocynthein
Coniferin, $C_{16}H_{22}O_8$	From *Coniferous woods*	Coniferyl alcohol
Convallamarin, $C_{23}H_{44}O_{12}$	From *Convallaria majalis*	Convallamaretin
Convallarin, $C_{34}H_{62}O_{11}$	From *Convallaria majalis*	Convallaretin
Convolvulin, $C_{31}H_{50}O_{16}$	From *Exogonium purga*	Convolvulinic acid and methyl-ethyl acetic acid
Crocin, $C_{44}H_{70}O_{28}$	From *Crocus sativus*	Crocetin
Daphnin, $C_{15}H_{16}O_9$	From *Daphne Mezereum*	Daphnetin
Datiscin, $C_{21}H_{22}O_{12}$	From *Datisca cannabina*	Datiscetin
Dhurrin, $C_{14}N_{17}NO_7$	From *Sorghum vulgare*	Parahydroxybenzaldehyde and hydrocyanic acid
Digitalin, $C_{35}H_{56}O_{14}$	From *Digitalis purpurea*	Digitaligenin and digitalose
Digitonin	" " "	Digitogenin and galactose
Elaterin, $C_{20}H_{28}O_5$	From *Elaterium*	
Fraxin, $C_{32}H_{36}O_{20}$	From *Fraxinus Ornus*	Fraxetin
Gentiopicrin, $C_{20}H_{30}O_{12}$	From *Gentiana lutea*	Gentiogenin
Globularin, $C_{20}H_{44}O_{14}$	From *Globularia Alypum*	Globularetin
Glycyrrhizin, $C_{44}H_{63}NO_{18}$	From *Glycyrrhiza glabra*	Glycyrrhetin
Gratiolin, $C_{20}H_{34}O_7$	From *Gratiola officinalis*	Gratioletin and gratiolaretin
Gratiosolin, $C_{46}H_{84}O_{25}$	From *Gratiola officinalis*	Gratiosoletin
Helicin, $C_{13}H_{16}O_7$	From Salicin	Salicyl aldehyde
Indican, $C_{14}H_{17}NO_6$	From *Indigofera anil*	Indoxyl
Jalapin, $C_{68}H_{112}O_{32}$	From *Exogonium purga*	Jalapinol
Lotusin, $C_{28}H_{31}NO_{16}$	From *Lotus arabicus*	Lotoflavin and hydrocyanic acid
Ononin, $C_{30}H_{34}O_{13}$	From *Ononis spinosa*	Formonetin
Phillyrin, $C_{27}H_{34}O_{11}$	From *Phillyria latifolia*	Phillygenin
Phloridzin, $C_{21}H_{24}O_{10}$, N.N.R.	From the bark of the pear, apple, cherry and plum tree	Phloretin
Pinipicrin, $C_{22}H_{36}O_{11}$	From *Thuja occidentalis*	Ericinol
Populin, $C_{20}H_{22}O_8$	From different species of Populus	Benzoic acid, saliretin
Prophetin, $C_{23}H_{36}O_7$	From *Cucumis prophetarum*	Propheretin
Quercitrin, $C_{36}H_{38}O_{30}$	From *Quercus tinctoria*	Quercetin and rhamnose
Quinovin, $C_{38}H_{62}O_{11}$	From the bark of Cinchonas	Quinovic acid
Salicin, $C_{13}H_{18}O_7$	From different species of Salix and Populus	Saligenin
Santonin, $C_{15}H_{18}O_3$	From *Artemisia pauciflora*	Santoniretin
Saponin, $C_{32}H_{22}O_{12}$	From *Saponaria officinalis*	Saponetin
Sinigrin, $C_{10}H_{18}O_{10}NKS_2$	From *Sinapis nigra*	Allyl isothiocyanate
Thujin, $C_{20}H_{22}O_{12}$	From *Thuja occidentalis*	Thujigenin and thujetin
Xanthorhamnin, $C_{48}H_{66}O_{29}$	From *Rhamnus amygdalinus*	Rhamnetin

GENTIANA. U. S. Gentian

[Gentian.—Yellow Gentian Root]

Gentian is the dried rhizome and roots of *Gentiana lutea* Linné (Fam. *Gentianaceæ*).

Gentian yields not less than 30 per cent of water-soluble extractive.

Description—In nearly cylindrical pieces or longitudinal slices, about 25 mm. thick, the upper portion closely annulate, the lower portion longitudinally wrinkled; externally deep yellowish-brown; internally lighter; somewhat flexible and tough when damp; rather brittle when dry;

fracture uneven; the bark rather thick, separated from the somewhat spongy meditullium by a black cambium line; odor peculiar, faint, more prominent when moistened; taste sweetish and persistently bitter.

For further description see the U. S. P. X.

U. S. P. Preparation—Tinctura Gentianæ Composita.

N. F. Preparations—Elixir Gentianæ (from Fluidextract); Elixir Gentianæ et Ferri (from Fluidextract); Elixir Gentianæ et Ferri Phosphatis (from Fluidextract); Elixir Gentianæ Glycerinatum (from Fluidextract); Extractum Gentianæ; Fluidextractum Gentianæ; Infusum Gentianæ Compositum; Pilulæ Antiperiodicæ (from Extract); Pilulæ Antiperiodicæ sine Aloe (from Extract); Pilulæ Ferri, Quininæ, Aloes et Nucis Vomicæ (from Extract); Tinctura Amara; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe; Tinctura Rhei et Gentianæ.

Gentian contains the glucoside *gentiopicrin*, $C_{20}H_{30}O_{12}$ (which splits, when heated with dilute acids, into gentiogenin and glucose), *gentisic acid*, $C_{14}H_{10}O_5$, pectin, sugar (*gentianose*), and a little fixed oil. A dark green coloration is produced when a ferric salt is added to a preparation of gentian; this is said to be due to the reaction with gentisic acid. If the preparation is treated with ferric hydroxide, and then filtered, or if mixed with an alkaline citrate, the tendency to become discolored is lost.

Uses—Gentian is a bitter tonic. Dose, fifteen grains (1 Gm.).

CALUMBA. U. S. Calumba

[**Calumb.**—Columba, Columbo, Colombo]

Calumba is the dried root of *Jateorrhiza palmata* (Lamarck) Miers (Fam. *Menispermaceæ*).

Calumba yields not more than 2.5 per cent of acid-insoluble ash.

Description—In nearly circular disks, 3 to 6 cm. in diameter, externally greenish-brown and wrinkled, internally yellowish or grayish-yellow, depressed in the center, with a few interrupted circles of projecting wood-bundles, distinctly radiate in the outer portion; fracture short, mealy, odor slight; taste mucilaginous, slightly aromatic, very bitter.

U. S. P. Preparation—Tinctura Calumbæ.

N. F. Preparation—Fluidextractum Calumbæ.

This African root owes its virtues to a number of principles, the most important being *columbin*, $C_{21}H_{22}O_7$, and *berberine*, both of which are very bitter; starch and colombic acid are present, with a mucilage which is often troublesome by interfering with percolating operations. Calumba must not be in very fine powder if it is to be percolated with diluted alcohol.

Uses—It is a bitter tonic. Dose, thirty grains (2 Gm.).

QUASSIA. U. S. Quassia

[**Quass.**—Bitter Wood]

Quassia is the wood of *Picrasma excelsa* (Swartz) Planchon, known in commerce as Jamaica Quassia, or of *Quassia amara* Linné, known in commerce as Surinam Quassia (Fam. *Simarubaceæ*).

Description—*Jamaica Quassia*—Usually in chips, raspings or shavings, occasionally in small cubes or billets; yellowish-white or bright yellow, with a few light gray pieces somewhat coarsely grained; fracture tough, fibrous. Odor slight; taste bitter.

Surinam Quassia—The crude drug and microscopic sections closely resemble the Jamaica variety; tracheæ usually single or in pairs, sometimes in groups of 3 or 4; medullary rays in narrower and larger groups than in the Jamaica variety, from 1 to 4 cells wide and from 10 to 30 rows deep; calcium oxalate crystals few or entirely absent, thus distinguishing the variety from Jamaica Quassia.

For further description see the U. S. P. X.

N. F. Preparations—Fluidextractum Quassiæ; Tinctura Quassiæ.

Quassia contains *quassin* (*picrasmin*), $C_{32}H_{44}O_{10}$, which is intensely bitter, and soluble in both alcohol and water; there are also present resin, mucilage, etc.

History—The drug was sent to Linnaeus in 1763 by one of his correspondents in Surinam, with the statement that it was the basis of a valuable secret remedy employed by a negro slave named "Quassi". Linnaeus therefore named the plant Quassia.

Uses—It is a bitter tonic. Dose, eight grains (0.5 Gm.).

DIGITALIS. U. S. Digitalis

[**Digit.**—Foxglove, Digitalis Folium P. I.]

Digitalis is the dried leaf of *Digitalis purpurea* Linné (Fam. *Scrophulariaceæ*).

Digitalis, in the form of the tincture, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose (the minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.006 cc. of tincture, equivalent to 0.00,000,05 Gm. of ouabain for each gram of body weight of frog. It contains not more than 2 per cent of browned leaves, stems, flowers, or foreign organic matter, and yields not more than 5 per cent of acid-insoluble ash.

Description—From 10 to 30 cm. long; ovate or ovate-oblong, narrowed into a petiole; crenate; dull green, densely and finely pubescent; wrinkled above; paler and reticulate beneath; midrib near the base broad; odor slight, somewhat tea-like; taste bitter, nauseous.

For a further description see the U. S. P. X.

Assay—Prepare a tincture according to the official process and proceed as directed under *Tinctura Digitalis*.

This assay is explained on page 1504.

U. S. P. Preparations—Infusum Digitalis; Tinctura Digitalis.

N. F. Preparations—Fluidextractum Digitalis; Pilulæ Digitalis, Scillæ et Hydrargyri; Pilulæ Opii, Digitalis et Quininæ.

Digitalis has been the subject of exhaustive investigation. The constituents which are recognized as being of the greatest importance are *digitalin*, a glucoside, *digitonin*, a saponin-like glucoside, *digitalein* (a mixture), and *digitoxin*. Other principles are also known, *digitoflavin*, *digitin*, *digitophyllin*, fat, etc. *Digitoxin*, $C_{34}H_{54}O_{11}$, is the chief active principle. It is given in a dose of 1/130 grain, but not more than 1/65 grain in twenty-four hours. Its effects must be carefully watched and the dose regulated accordingly. Much confusion exists concerning the commercial products sold as *digitalin*. The *French digitalin* of Nativelle (*Homolle's digitalin*) is very active; the dose is 1/250 to 1/40 grain. It must be used with caution. The *German digitalin* is chiefly digitonin, and is administered in a dose of 1/10 to 1/2 grain. *Digitalin, True* (*Schmiedeberg's Digitalin* or *Digitalinum Verum Kiliani*), $C_{35}H_{36}O_{14}$, is obtained commercially from German digitalin. Its dose is variable; 1/130 grain is usually given as the commencing dose. *Digitalein, crude*, is a mixture of glucosides from digitalis, prepared according to the process of Schmiedeberg. The dose is 1/60 to 1/30 grain, several times daily.

History—The common name Foxglove is a corruption of an old vernacular name "foxes glew" which meant "foxes music". The Norwegian name means "fox bells". The German name "finger hut" means thimble, and Füchs a German botanist of the sixteenth century Latinized this name as Digitalis. It was first official in the London Pharmacopœia of 1650. Its later extensive use in medicine arose from the publicity given it by Dr. William Withering,

Birmingham, England, in 1785; hence the infusion has often been called *Withering's infusion.*

Uses—Digitalis is used as a cardiac tonic and stimulant, slowing and strengthening the heart beat. Dose, one and one-half grains (0.1 Gm.).

Digitalis Principles and Preparations

The following discussion is an abstract from the 1925 N. N. R and the active principles and preparations of Digitalis approved by the N. N. R. are appended.

The digitalis group embraces many crude drugs and proximate principles which have a peculiar action on cardiac muscle. Digitalis and strophanthus have been investigated far more than others and much more information is available concerning their action.

Cardiac Action—The cardiac action of the individual drugs of the digitalis group is similar and the claims made for the different preparations concern the removal of the disadvantages that have been experienced in the use of the drugs belonging to the digitalis group. The first disadvantage of digitalis medication is the varying strength of the crude drugs. This uncertainty can be avoided by the use of the isolated, definite principles or to a considerable extent by the use of physiologically standardized preparations. To the latter group belong the U. S. P. Tincture of Digitalis and the N. F. Fluidextract of Digitalis. The tincture is the more dependable preparation, the fluidextract being chiefly employed in veterinary practice.

Differences in Emetic Action—The digitalis principles are irritant to certain mucous membranes and the subcutaneous tissues and it has been deduced that the nausea and vomiting which sometimes follow the oral administration of these drugs result from irritation of the gastro-intestinal tract. It has been shown, however, that digitalis does not markedly irritate the stomach or intestines directly, but that its preparations cause nausea and vomiting almost entirely through their action on the heart itself. It has been shown, also, that the emetic action is roughly proportional to the cardiac effects of the various members of the group, and when this undesired action is induced it cannot, as a rule, be avoided by changing the mode of administration or by resorting to other members of the group.

Differences in Absorption—Digitalis and its preparations representing the entire drug and also digitoxin are absorbed fairly readily from the alimentary tract, and hence their actions may be limited to the therapeutic stage, whereas strophanthus and strophanthin are absorbed more slowly and irregularly with correspondingly greater difficulty in limiting their actions to those desired, when they are administered by the mouth. This disadvantage has been overcome by administering strophanthin intramuscularly or intravenously, in much smaller doses, however.

Differences in Cumulative Action—The effects of all the digitalis bodies are said to be cumulative. This cumulative effect is especially pronounced in the case of digitalis itself and digitoxin. It is much less pronounced in the case of strophanthus, strophanthin and true digitalin.

Digitalis Principles—The disadvantages of all the drugs of the digitalis group have served as a constant stimulus in the search for pure principles suitable for subcutaneous and intravenous administration; but despite the numerous investigations directed toward this end, the chemistry of digitalis and other members of the group is very imperfectly understood. Several digitalis principles have been isolated in a greater or less degree of purity. Of these, digitoxin and digitalin together represent very nearly the crude drug digitalis. The digitalin on the market, however, is not the true digitalin, but the different brands consist of mixtures of two or more principles.

It must be remembered, therefore, that Merck's "crystallized" digitalin, Merck's "pure" digitalin and the "true" digitalin of Boehringer and Soehne, which naturally might be supposed to be identical, differ somewhat in their action.

Proprietary Digitalis Preparations—Several digitalis preparations have been introduced into therapeutic use with the claim that they are composed either of pure principles, or of purified extracts of digitalis, and that they are devoid of certain disadvantages possessed by the preparations of the U. S. Pharmacopœia.

It may be said at once that there is no proof that any of these proprietary preparations can be used to greater advantage than digitalis and its galenicals in the majority of cases of cardiac disease.

Digalen Roche (Cloetta), N. N. R.—A sterile solution containing in each cubic centimeter 0.3 Gm. of an active derivative of digitalis as isolated by Cloetta, containing 7.5 per cent of alcohol.

It is a colorless or slightly yellowish liquid of an agreeable aromatic odor, with a sweet taste which subsequently becomes bitter.

The active derivative contained in digalen-Roche (Cloetta) is an amorphous, white or slightly yellow powder. It is stated to have a solubility five times as great as that of crystallized digitoxin. It is stated to dissolve readily in alcohol and in chloroform and less readily in ether. It has an intensely bitter taste and causes violent sneezing.

Manufactured by the Hoffmann-La Roche Chemical Works, New York. No U. S. patent.

Its uses are the same as for digitalis.

The average dose is from 1 to 2 cc. (15 to 30 minims). The maximum daily dosage is 6 cc. (90 minims). Digalen-Roche (Cloetta) is also suitable for intramuscular and intravenous injection. Intravenous injections of 1 cc. (15 minims) may be repeated at intervals of one-half to one hour as necessary.

U. S. trademarks 43,593; 83,738.

Digitalein, Crude, N. N. R.—**Digitaleinum Crudum**—A mixture of glucosides from *Digitalis purpurea* prepared according to the process of Schmiedeberg, containing digitoxin, digitalin and digitalein.

Commercial digitalein is an amorphous, yellowish-white, bitter powder, soluble in water and in absolute alcohol, insoluble in chloroform and in ether. The aqueous solution foams on shaking. The solution yields a precipitate on the addition of lead acetate, ammonia water or tannic acid.

Uses—Digitalein acts like digitalis on the heart.

Its uses are the same as those of digitalis.

The dose is from 0.001 to 0.002 Gm. ($\frac{1}{60}$ to $\frac{1}{30}$ grain), two or three times a day.

Digitalin, True, N. N. R.—**Digitalinum Verum Kiliani**—Schmiedeberg's Digitalin—$C_{35}H_{36}O_{14}$—A glucoside found in the seeds and leaves of *Digitalis purpurea* and derived commercially from "German" digitalin.

It is a white amorphous powder, or in characteristic, granular masses. It melts at 217° C. and becomes yellow. It is soluble in 1000 parts of water and in 100 parts of 50 per cent alcohol, but nearly insoluble in ether and chloroform. Digitalin dissolved in alcohol, and treated with very dilute acid and heat yields digitaligenin and two sugars.

Uses—The same as those of digitalis. Its action is not so persistent as that of digitoxin. True digitalin is more actively emetic than the other digitalis bodies in proportion to its cardiac activity, and it probably has no advantages over the better known members of the group.

Dose—It is impossible at present to state the correct dose for digitalinum verum Kiliani. Some authorities have given the same dose as that of digitoxin, whereas others correctly give it as much larger. At least, it is quite certain that digitalin is not so active as digitoxin. It is best given in pills made by trituration with sugar of milk and massing with glucose. Aqueous solutions of digitalin rapidly lose their strength and should be freshly prepared.

Digitalin, "French", N. N. R.—Homolle's Digitalin—Digitaline Amorphe—Digitaline Chloroformique—A mixture obtained from *Digitalis purpurea* by the method of Homolle, consisting mainly of digitalinum verum Kiliani.

"French" digitalin is a yellowish-white amorphous powder of a peculiar aromatic odor and little taste. It is neutral to litmus, almost insoluble in water, soluble in alcohol and chloroform and insoluble in ether. It softens at 90° C. and begins to melt at 100° C. It is not precipitated by solutions of lead salts, but with tannic acid it forms a tannate insoluble in water. Concentrated sulphuric acid dissolves digitalin "French", producing a yellow color, which finally changes to an emerald-green.

Uses—Its action is like that of digitoxin. Its uses are the same as those of digitalis.

Dose—What has been said with regard to the dose of digitalinum verum applies to the "French" digitalin; the dose is variously given as from 0.00025 to 0.002 Gm. ($\frac{1}{240}$ to $\frac{1}{30}$ grain). The maximum daily dose is 0.006 Gm. ($\frac{1}{10}$ grain). It must be used with caution and its action carefully watched.

Digitalin, "German", N. N. R.—**Digitalinum Germanicum**—A mixture of glucosides obtained from digitalis seeds according to the process of Walz, and consisting largely of digitonin, with digitalin verum and other glucosides.

Note—Digitonin is given as a synonym for crystallized digitalin by some manufacturers; and it is to be observed particularly that this is quite different from "true digitalin" or the "crystalline digitaline" of the French Pharmacopœia.

"German" digitalin is a yellowish-white amorphous powder, soluble in water and alcohol, insoluble in ether and chloroform. It is said to contain from about 50 to 60 per cent of digitonin and from 5 to 6 per cent of digitalinum verum, the remainder being digitalein and other glucosides.

Sulphuric acid containing a trace of ferric sulphate produces with digitalin "German", an intense golden-yellow coloration, changing to red and finally to a permanent reddish-violet.

Uses—These are similar to those of digitalis.

Dose—What has been said of the uncertainty of dosage of true digitalin must obviously apply with even greater force to "German" digitalin, since the activity of the latter probably depends mainly on the true digitalin that it contains. The dose of "German" digitalin was formerly given as 0.001 to 0.002 Gm. ($\frac{1}{60}$ to $\frac{1}{30}$ grain), maximum dose 0.004 Gm. ($\frac{1}{15}$ grain), with a maximum per day of 0.02 Gm. ($\frac{1}{3}$ grain). Many clinicians, however, have used very much larger doses without ill effects, and the relative activity of certain specimens of the "German" digitalin and other members of the group would seem to indicate that such specimens of "German" digitalin might be given safely in daily doses of a grain, or possibly more.

As "German" digitalin (so-called *digitalinum purum*) is a mixture of very powerful active principles, the proportion of which may vary with changes in the manipulations, it is important that the directions for its preparation as given in Hager's Handbuch der pharmacistischen Praxis, 1; 1032, 1903, should be carefully followed, and caution should be exercised to purchase only such products as the manufacturers can guarantee to have been made with the necessary care.

Digitoxin, N. N. R.—**Digitoxinum**—Digitaline Cristallisés (Nativelle)—$C_{34}H_{54}O_{11}$—A glucoside occurring in the leaves of *Digitalis purpurea*. It is the chief active principle of digitalis.

Digitoxin occurs in thin, colorless, rectangular, anhydrous leaflets, odorless and having a bitter taste. It is slightly soluble in water, ether and amylic alcohol; easily soluble in alcohol and in chloroform; insoluble in benzin or carbon disulphide; slightly soluble in fatty oils. Digitoxin should not melt below 240° C. If a fragment of digitoxin is dissolved in 2 cc. of glacial acetic acid containing a trace of ferric chloride and the solution poured on 2 cc. of concentrated sulphuric acid, a brown color should be produced at the zone of contact of the two liquids. This color gradually changes to green and finally to indigo blue; after half an hour the entire acetic acid layer will become blue. Digitoxin dissolves in cold, concentrated, hydrochloric acid to a colorless solution, but if this solution be heated on the water bath for some time a green color should be obtained.

Digitoxin dissolves in concentrated sulphuric acid with the production of a green color. If dried at 100° C., digitoxin should not lose more than 1 per cent of its weight (limit of *adhering moisture*).

Uses—Digitoxin acts much like digitalis.

The cardiac action of digitoxin is persistent, and when the therapeutic effects have passed off, a smaller amount will be required as a rule to reinstate the desired effects than were needed in the first instance. Locally, it is extremely irritant; hence it cannot be used for subcutaneous or intramuscular injection.

Dose—The toxicity of digitoxin, though very great, has been exaggerated, probably owing to the appearance of symptoms after too frequent repetition of the dose, and the single dose has been given as 0.00025 Gm. ($\frac{1}{240}$ grain), and a maximum daily dose of 0.001 Gm. ($\frac{1}{60}$ grain). These doses are undoubtedly too small when it is desired to induce the therapeutic action promptly, though they are approximately accurate when the dosage is to be continued for a time after the therapeutic effects are induced. A sharp distinction should, therefore, be made between the single or daily dose for *continued use* after the desired effects have been induced and the dose required at the beginning of treatment.

The beginning single dose is 0.0005 Gm. ($\frac{1}{120}$ grain), and the maximum beginning daily dose is 0.001 Gm. ($\frac{1}{60}$ grain). The dose must be reduced, or stopped, immediately when the therapeutic effect or toxic symptoms are induced.

Antidotes: Emetics, tannin, nitroglycerin, morphine, alcoholic stimulants or camphor.

Related Digitalis Principles

Cymarin, N. N. R.—A neutral, nonglucosidal substance obtained from *Apocynum cannabinum* or *Apocynum androsemifolium*.

Cymarin occurs as colorless, thick, prismatic crystals possessing a bitter taste. It is only slightly soluble in cold water, more soluble in hot water. It is with difficulty soluble in benzene, ether and carbon disulphide, but dissolves easily in acetone, alcohol and chloroform. When heated it begins to soften at 130° C. and becomes completely liquid at from 135° to 140° C. Cymarin is very sensitive even to weak organic acids, although it is not a glucoside.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Company, and sold by the Winthrop Chemical Company.

Uses—Its uses are much like those of digitalis, but it is not absorbed so readily from the gastro-intestinal tract, at least in animals, and probably in man; hence it is better suited for those cases in which intramuscular or intravenous injection is required to elicit the action promptly. (The usual precautions are necessary.)

Dose—Single dose for *oral administration* 0.0003 Gm. ($\frac{1}{2000}$ grain); daily 0.001 to 0.002 Gm. ($\frac{1}{60}$ to $\frac{1}{30}$ grain). Single or daily dose by intravenous or intramuscular injection, 0.0005 to 0.001 Gm. ($\frac{1}{120}$ to $\frac{1}{60}$ grain). Cymarin is sold only in the form of Tablets of Cymarin and Ampuls of Cymarin Solution.

Ouabain, Crystallized, N. N. R.—Ouabanium—Crystallized Strophanthin—G-Strophanthin Thoms—$C_{30}H_{46}O_{12}.9H_2O$—A glucoside, obtained from *Acokanthera ouabaio* by Arnaud, or, as now commonly prepared, from *Strophanthus gratus*, in which case it is also called crystallized strophantin, or g-strophanthin Thoms (see also page 1069).

Uses—The pharmacologic action of crystallized ouabain is probably qualitatively identical to that of the official strophanthus or strophanthin, but the crystallized ouabain is more active than the official strophanthin when injected subcutaneously or intravenously. This action develops more rapidly, the drug is more quickly excreted, and shows less tendency to cumulative action than does digitalis.

Crystallized ouabain is used in place of strophanthus or strophanthin as a substitute for digitalis.

Ouabain forms colorless quadratic crystals which are easily soluble in hot water, soluble in 100 parts of cold water and 30 parts of cold absolute alcohol and 30 parts of amyl alcohol. It is slightly soluble in acetic ether, ether and chloroform. Its solubilities require further study. Solutions of 1 part of ouabain in 100 parts of 95 per cent alcohol have been frequently observed to deposit crystals on standing.

Dose—Ouabain is absorbed so slowly and so irregularly from the alimentary canal that the oral administration of the drug is not to be recommended and is even considered unsafe.

For intravenous or intramuscular administration the dose is 0.0005 Gm. ($\frac{1}{120}$ grain) and this dose should not be repeated as a rule within less than twenty-four hours. It is best employed dissolved in from 4000 to 8000 parts of physiologic solution of sodium chloride. When the intramuscular or intravenous dose is to be repeated within less than twenty-four hours, a smaller amount should be administered.

Since ouabain solutions may deteriorate rapidly, only recently prepared solutions or solutions which have been recently tested should be used.

Strophanthin, U. S. P.—**Strophanthinum**—For description, see page 1069.

Digipoten, N. N. R.—A mixture of the digitalis glucosides in soluble form, diluted with milk-sugar to give the preparation an activity equal to that of digitalis leaves of standard quality. It is standardized by the "one hour frog method". The minimum lethal dose of digipoten per gram of body weight of frog is 0.0006 Gm.; or the equivalent in digipoten of 0.0005 mg. of ouabain for each gram of body weight of frog. It is virtually free from digitosaponin.

Digipoten is a pale green powder, possessing the characteristic bitter taste of digitalis. It is soluble in water and in 25 per cent alcohol.

Uses—Digipoten has the same activity as digitalis leaf of good quality and may be used like the official drug with respect to indications and dosage.

Dose—The dose is the same as that of digitalis.

Manufactured by The Abbott Laboratories, Chicago.

Digitan, N. N. R.—First introduced as *digipuratum*—A digitalis preparation said to contain digitoxin and digitalin in the form of tannates. It is standardized biologically by the method of Gottlieb. It is claimed that in digitan 85 per cent of the inactive substances found in the ordinary extract have been removed and that it is free from digitonin.

Digitan is a greenish-yellow, odorless, bitter powder. The active constituents of digitan are insoluble in cold water and diluted acids, but are easily soluble in weak alkalies.

The uses and dose are the same as those of digitalis.

Manufactured by Merck & Company, New York.

Digitol, N. N. R.—A biologically standardized fat. Free tincture of digitalis similar to the U. S. P. X tincture.

Tincture No. 111 Digitalis, N. N. R.—A fat-free tincture of digitalis claimed to be 50 per cent stronger than the tincture of the U. S. P.

The dose must be correspondingly reduced. Manufactured by Parke, Davis and Company.

SCILLA. U. S. Squill

[Scill.]

Squill is the cut and dried fleshy inner bulb scale of the white variety of *Urginea maritima* (Linné) Baker (Fam. *Liliaceæ*).

Squill, in the form of the tincture, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose (minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.006 cc. of tincture, equivalent to 0.00,000,05 Gm. of ouabain, for each gram of body weight of frog.

Description and Physical Properties—*Unground Squill*—In irregular, curved or flattened pieces, from 0.5 to 5 mm. in length; yellowish-white, somewhat translucent; brittle when dry and tough and flexible when damp, odor slight, taste bitter, mucilaginous and acrid.

Structure—Upper and lower epidermal layers of thin-walled cells with few stomata; mesophyll of slightly elongated thin-walled cells, sometimes containing spheroidal aggregates of a sugar; occasional bundles of spiral and reticulate tracheæ; numerous, elongated mucilage cells containing raphides of calcium oxalate; few spheroidal starch grains in the parenchyma.

Powdered Squill—Light yellowish-brown; very hygroscopic, caking in moist atmosphere; raphides of calcium oxalate numerous, up to 1 mm. in length, isolated and in bundles imbedded in mucilage; fragments of thin-walled parenchyma with occasionally spiral and reticulate tracheæ; very few starch grains.

Assay—Prepare a tincture according to the official process and proceed as directed under *Tinctura Digitalis*.

For an explanation of this assay see page 1505.

Preserve in tightly-closed containers, in a dry place.

U. S. P. Preparations—Acetum Scillæ; Fluidextractum Scillæ; Syrupus Scillæ (from Vinegar); Syrupus Scillæ Compositus (from Fluidextract); Tinctura Scillæ.

N. F. Preparations—Mistura Pectoralis, Stokes' (from Fluidextract); Oxymel Scillæ (from Vinegar); Pilulæ Digitalis, Scillæ et Hydrargyri.

Squill contains the bitter principle *scillipicrin*, also *scillin*, and *scillitoxin* (*scillain*), a poisonous glucoside. There is also present a large quantity of mucilage analogous to dextrin, which Schmiedeberg calls *sinistrin* $(C_6H_{10}O_5)_n$; also calcium oxalate, etc. Water and alcohol extract its virtues.

Uses—It is expectorant, emetic, and diuretic. Dose, one and one-half grains (0.1 Gm.). It is sometimes used as a rat poison and is said to be very effective.

STROPHANTHUS. U. S. Strophanthus

[Strophanth.—Strophanthus Seed]

Strophanthus is the dried, ripe seed of *Strophanthus Kombé* Oliver or of *Strophanthus hispidus* De Candolle (Fam. *Apocynaceæ*), deprived of the awns.

Strophanthus, in the form of the tincture, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose (the minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.00,006 cc. of tincture, equivalent to 0.00,000,05 Gm. of ouabain, for each gram of body weight of frog.

Description—About 15 mm. long and 4 or 5 mm. broad, oblong-lanceolate, flattened and obtusely edged, grayish-green, covered with appressed, silky hairs, one side with a ridge extending into the attenuated, pointed end; kernel white and oily, consisting of a straight embryo, having two thin cotyledons, and surrounded by a thin layer of perisperm; nearly inodorous; taste very bitter.

Assay—Prepare a tincture by the official process and proceed as directed under *Tinctura Digitalis*.

This assay is explained on page 1505.

For a further description see the U. S. P. X.

U. S. P. Preparation—Tinctura Strophanthi.

Strophanthus contains a glucoside, *strophanthin*, kombic acid, fatty matter, resin, extractive, etc. Strophanthin is the active principle. Alcohol and water extract it. Purified petroleum benzin is used to percolate the drug to deprive it of the fatty matter before exhaustion with alcohol in making the tincture.

Uses—Strophanthus is used as a cardiac tonic and stimulant in the dose of one grain (0.06 Gm.).

STROPHANTHINUM. U. S. Strophanthin

[Strophanthin.]

A glucoside or a mixture of glucosides obtained from *Strophanthus Kombé* Oliver (Fam. *Apocynaceæ*).

Preparation—This glucoside may be made by exhausting strophanthus with alcohol acidulated with hydrochloric acid, evaporating the liquid to a soft extract, treating this with water, and shaking the aqueous liquid with chloroform to remove the fatty matter; the aqueous liquid is evaporated to obtain the crystals of strophanthin.

Description and Physical Properties—A white or yellowish powder containing varying amounts of water, which it does not lose entirely without decomposition. It is stable in the air.

Caution—Strophanthin is extremely poisonous.

Strophanthin is soluble in water and in diluted alcohol, but less soluble in dehydrated alcohol. It is nearly insoluble in chloroform, ether, and benzene.

Tests for Identity and Purity—Solutions of Strophanthin are neutral to litmus paper, and are dextrorotatory.

Sulphuric acid added to Strophanthin produces an emerald-green color, changing to brown.

Add a trace of ferric chloride T.S. and a few cc. of sulphuric acid to an aqueous solution of Strophanthin (1 in 50): a red precipitate is produced, which turns dark green after one or two hours.

A solution of 0.1 Gm. of Strophanthin in 15 cc. of distilled water, when mixed with 5 cc. of hot alkaline cupric tartrate solution, produces no precipitate. On heating an aqueous solution to 70° C. with a small amount of diluted hydrochloric acid, the Strophanthin is hydrolyzed into strophanthidin, which precipitates, and a sugar, capable of reducing alkaline cupric tartrate solution, which remains in solution.

The ash from 0.1 Gm. is negligible.

Preserve in well-closed containers, protected from light.

Uses—Strophanthin is used as a cardiac stimulant in the following dose: by the mouth, 1/60 grain (0.001 Gm.); intravenous, 1/120 grain (0.0005 Gm.).

SALICINUM. U.S. Salicin

[Salicin.]

A glucoside [$C_{13}H_{18}O_7$] obtained from several species of *Salix* and *Populus* (Fam. *Salicaceæ*).

Preparation—A boiling concentrated decoction of the bark is treated with lead oxide or basic lead acetate until it becomes nearly colorless. Gum, tannin, and extractive matter, which would impede the crystallization of the salicin, are thus removed from the liquid; while a portion of the oxide is dissolved, in combination probably with the salicin. To separate this portion of oxide, sulphuric acid is first added, and then barium sulphide, and the liquor is filtered and evaporated. Salicin is deposited, and may be purified by repeated solution and crystallization. It has been produced synthetically from helicin. It may also be prepared by boiling the bark with milk of lime to remove tannin, evaporating the filtrate to a soft extract, digesting this with alcohol, distilling off the alcohol, and obtaining the salicin in crystals from the residue. Salicin is a glucoside, splitting into saligenin and sugar under the influence of dilute acids and heat.

Description and Physical Properties—Colorless, silky, shining needles or prisms, or a white, crystalline powder. It is odorless and has a very bitter taste.

One Gm. of Salicin is soluble in 23.5 cc. of water and in 88.5 cc. of alcohol, at 25° C. One Gm. is soluble in 3.3 cc. of water at 80° C., and in 30 cc. of alcohol at 60° C. It is soluble in chloroform and in ether.

Tests for Identity—Salicin melts between 199° and 202° C.

Its aqueous solution (1 in 30) is neutral to litmus paper, and is lævorotatory.

Heat a small portion of Salicin in a test tube until it turns brown, add a few cc. of distilled water, and a drop of ferric chloride T.S.: a violet color is produced.

With sulphuric acid Salicin gives a red color which disappears on the addition of distilled water.

Heat gently about 0.1 Gm. of Salicin with about 0.2 Gm. of potassium dichromate and 2 cc. of diluted sulphuric acid: the fragrant odor of salicylic aldehyde is developed.

Tests for Purity—Ash: not more than 0.05 per cent.

Ten cc. portions of an aqueous solution of Salicin (1 in 50) yield no precipitate on the addition of 1 cc. of tannic acid T.S., picric acid T.S., or mercuric potassium iodide T.S. (*alkaloids*), and another 10 cc. portion is not colored violet by a drop of ferric chloride T.S. (*salicylic acid*).

An aqueous solution of Salicin meets the requirements of the test for *heavy metals*, page 1519.

Preserve in well-closed containers.

Uses—Salicin is used in rheumatic conditions, in doses of fifteen to thirty grains (1 to 2 Gm.).

SANTONINUM. U.S. Santonin

[Santonin.]

The inner anhydride [$C_{15}H_{18}O_3 = 246.22$] of santoninic acid. It is obtained from *Artemisia pauciflora* (Ledebour) Weber (Fam. *Compositæ*).

Preparation—It is prepared from santonica which contains santonin, artemisin, resin, volatile oil, gum, etc., and is made by exhausting the santonica mixed with lime, using diluted alcohol, distilling off the alcohol, and adding acetic acid to the residue. The precipitated santonin is purified by dissolving

it in alcohol, treating with animal charcoal, and crystallizing. Santonin forms soluble compounds with alkalies, and it may be precipitated from its solutions by acids. Soluble compounds of santonin are unsuited for medicinal uses, because the comparative insolubility of santonin in neutral or acid liquids is one of its great advantages for use as an anthelmintic.

Description and Physical Properties—Colorless, shining, flattened rhombic prisms or a white, crystalline powder. It is odorless, and nearly tasteless at first, but afterwards develops a bitter taste. It is stable in the air, but rapidly becomes yellow on exposure to light.

Santonin is almost insoluble in cold water, and only slightly soluble in boiling water. One Gm. of Santonin is soluble in 43 cc. of alcohol, 1.7 cc. of chloroform, and in 110 cc. of ether, at 25° C. One Gm. is soluble in 6.5 cc. of boiling alcohol.

Tests for Identity—Santonin melts between 169° and 171° C.

Its solution in alcohol (1 in 50) is neutral to litmus paper.

Its solutions are lævorotatory.

Heat about 0.2 Gm. of Santonin with 2 cc. of alcoholic potassium hydroxide T.S.: a red color is developed.

Shake about 0.01 Gm. of Santonin with a cool mixture of 1 cc. each of sulphuric acid and distilled water, heat the solution to 100° C., and add a drop of dilute ferric chloride solution (1 volume of ferric chloride T.S. to 10 volumes of distilled water): a violet color results.

Tests for Purity—Ash: not more than 0.1 per cent.

The solution of 0.1 Gm. of Santonin in 2 cc. of sulphuric acid is not darker than pale yellow (*readily carbonizable substances*).

Boil 0.5 Gm. of Santonin with 20 cc. of distilled water and 2 cc. of diluted sulphuric acid, cool and filter: the addition of mercuric potassium iodide T.S. or of iodine T.S. to 10 cc. of the filtrate: mixed with 10 cc. of distilled water, produces no cloudiness even after standing for three hours (*alkaloids*).

Preserve in well-closed containers protected from light.

N. F. Preparations—Tabellæ Santonini; Tabellæ Santonini Compositæ.

Uses—Santonin is used as an anthelmintic, in doses of one to two grains (0.06 to 0.125 Gm.).

SANTALUM RUBRUM. U. S. Red Saunders

See Chapter LX on coloring principles.

SARSAPARILLA. U. S. Sarsaparilla

[Sarsap.]

Sarsaparilla is the dried root of *Smilax medica* Chamisso and Schlechtendal, known in commerce as Mexican Sarsaparilla; or of *Smilax officinalis* Kunth, or of an undetermined species of *Smilax* known in commerce as Honduras Sarsaparilla, or of *Smilax ornata* Hooker filius known in commerce as Central American or Jamaica Sarsaparilla (Fam. *Liliaceæ*).

Sarsaparilla contains not more than 2 per cent of foreign organic matter, excepting the rhizome and crown portion, which must be removed before the root is ground and powdered. Mexican Sarsaparilla yields not more than 4 per cent of acid-insoluble ash. The other official varieties conform to the standards for acid-insoluble ash under Vegetable Drugs, Part IX.

Description—Sarsaparilla is nearly odorless; taste mucilaginous, somewhat sweetish and acrid.

Unground Mexican Sarsaparilla—Long roots from 3.5 to 6 mm. in diameter, frequently attached to a crown having one or more stout stems; usually shrunken, forming sharp longitudinal ridges and broad furrows; externally light grayish-brown to dark brown; the furrows may contain more or less blackish earth; finely hairy; nearly devoid of branches or fibrous rootlets; fracture of cortex brittle, of central cylinder tough and fibrous; cortex mealy and whitish or brownish and horny, woody zone yellow and porous; pith whitish and distinct.

Unground Honduras Sarsaparilla—Long roots from 2 to 5 mm., rarely 6 mm. in diameter and bound together by roots of the same plant into compact cylindrical bundles from 8 to 15 cm. in diameter; externally reddish-brown or dark brown, longitudinally wrinkled or finely furrowed with occasional fibrous rootlets; fracture short, sometimes tough and fibrous in the central cylinder; internally a reddish-brown, dark brown, or occasionally light gray cortex, a light yellow and porous woody zone and a whitish pith.

Unground Central American Sarsaparilla—Roots long, from 1 to 4, rarely 5 mm. in diameter; externally light brown or reddish-brown, longitudinally wrinkled, occasionally nearly smooth,

rarely furrowed and bearing numerous coarse fibrous rootlets; fracture short or tough and fibrous in the central cylinder; internally a white or dark brown cortex, a yellow, porous, woody zone and a yellow or white pith.

For further description see the U. S. P. X.

U. S. P. Preparations—Fluidextractum Sarsaparillæ; Syrupus Sarsaparillæ Compositum (from Fluidextract).

Sarsaparilla contains a glucoside analogous to, if not identical with, saponin, termed *parillin*. When boiled with dilute acids, it splits into *parigenin* and grape sugar. There are also present starch, resin, coloring matter, and extractive. Alcohol and water are good solvents.

History—This drug was first used in Europe in the sixteenth century as a much vaunted remedy for syphilis. The origin of the name is involved in doubt.

Uses—It is popularly believed to be an alterative. Dose, thirty grains (2 Gm.).

SENEGA. U. S. Senega

[**Seneg.**—Seneca Snakeroot, Senega Snakeroot]

Senega is the dried root of *Polygala Senega* Linné (Fam. *Polygalaceæ*).

Senega contains not more than 5 per cent of stems and other foreign organic matter.

Description—Usually in pieces; when entire, slenderly conical, with an enlarged crown; from 3 to 15 cm. in length and from 2 to 10 mm. in thickness; tortuous, somewhat branched and bearing a few rootlets; crown knotty with numerous buds and short stem-bases; externally brownish-yellow, the crown darker and rose-tinted; longitudinally wrinkled, frequently with a distinct ridge or keel; fracture short, wood pale yellow; odor suggesting methyl salicylate; taste sweetish, afterwards strongly acrid.

For further description see the U. S. P. X.

U. S. P. Preparations—Fluidextractum Senegæ; Syrupus Senegæ (from Fluidextract); Syrupus Scillæ Compositus (from Fluidextract).

N. F. Preparation—Mistura Pectoralis, Stokes' (from Fluidextract).

Senega contains *senegin*, $C_{32}H_{54}O_{18}$, *polygalic acid*, fixed oil, pectose, etc. *Senegin* is analogous to, if not identical with, saponin. Alcohol and water are good menstrua for extracting its virtues. Liquid preparations of senega are very apt to gelatinize, owing to the presence of pectin; this is obviated by using solution of potassium hydroxide or other alkali to dissolve it.

Uses—Senega is a valuable expectorant. Dose, fifteen grains (1 Gm.).

ADONIS. N. F. Adonis

[**Adon.**—Pheasant's Eye]

Adonis is the dried overground portion of *Adonis vernalis* Linné (Fam. *Ranunculaceæ*).

Adonis contains not more than 5 per cent of foreign organic matter.

It contains *adonin* or *adonidin*, also *aconitic acid*.

Description—Glabrous, with the exception of the younger portions which may be slightly grayish-puberulent; stems from 15 to 50 cm. in length, thick, but soft and weak; shining, simple or branched, the branches mostly from near the base and similar to the main stem; naked below, except for some scale-like leaf-vestiges, densely leafy above: leaves from 2 to 4 cm. in length and two-thirds or more as broad, pinnately divided into several segments, the larger of which are again divided, the ultimate segments being narrowly linear and acute; flowers terminal, yellow but usually drying to a cream color, from 3 to 6 cm. in breadth; sepals five, green or grayish-puberulent, more than half the length of the petals, oblong, obtuse, finely nerved; petals from five to twenty, oblong, obtuse, finely nerved; stamens indefinite; pistils numerous, in fruit forming an ovoid, obtuse, dense head of ovoid akenes, which are tipped with the very small, persistent styles. Odor faint; taste bitterish, afterward somewhat acrid.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Adonidis.

Uses—A substitute for digitalis, slowing the heart and increasing the heart beat. It is also used as a diuretic. Dose, two grains (0.125 Gm.).

ALETRIS. N. F. Aletris

[**Aletr.**—Unicorn Root, Star Grass]

Aletris consists of the dried rhizome and root of *Aletris farinosa* Linné (Fam. *Liliaceæ*).

Aletris contains not more than 5 per cent of foreign organic matter and yields not more than 10 per cent of acid-insoluble ash.

It contains a bitter principle and large amounts of starch.

Description—Rhizome horizontal or slightly oblique, nearly cylindrical or laterally compressed above, from 2 to 4 cm. in length and from 5 to 12 mm. in diameter; externally grayish-brown, upper portion with circular stem scars from 3 to 7 mm. in diameter and with numerous leaf bases, the sides and lower portion with numerous tough wiry, whitish or reddish-brown roots which are more or less flexuous and provided with short branches; fracture short; internally light brown, cortex from 1 to 2 mm. in thickness, central cylinder with numerous twisted and branching fibro-vascular bundles. Odor slight, acetous; taste sweetish, somewhat bitter.

For further description see the N. F. V.

N. F. Preparation—Elixir Viburni Opuli Compositum; Fluidextractum Aletridis.

Uses—It is used as a diuretic and uterine tonic. Dose, thirty grains (2 Gm.).

BRAYERA. N. F. Brayera

[**Brayer**—Kousso, Cusso]

Brayera is the dried panicle of the pistillate flowers of *Hagenia abyssinica* (Bruce) Gmelin (Fam. *Rosaceæ*).

Brayera contains not more than 10 per cent of staminate flowers or other foreign organic matter, and yields not more than 5 per cent of acid-insoluble ash. Reject stems over 3 mm. in diameter and all binding material before powdering or using the drug.

It contains a bitter, resinous principle, *kosin*, $C_{31}H_{38}O_{10}$, about 24 per cent of tannin, volatile oil, gum, etc.

Description—Usually in rolls or flattened bundles from 25 to 50 cm. in length, reddish-brown or occurring more or less loose and stripped from the larger portions of the panicles. Panicle branches cylindrical, somewhat flattened, longitudinally furrowed or wrinkled, externally light brown to yellowish, tomentose, glandular; internally, cork brownish, bast- and wood-fibers yellow, fibro-vascular, bundles in wedges, pith large and yellowish-brown; nodes distinct, each with a scar or branch and subtended by a sheathing bract; internodes mostly from 1 to 2 cm. in length; flowers subtended by two ovate, reddish, pubescent and glandular bracts; pedicel short; calyx turbinate, pubescent below, subtended by four or five rigid, spreading, obovate, purple-veined bractlets which are persistent and elongated in fruit, alternating with and larger than the five usually shriveled, reflexed calyx lobes; petals five, caducous, and usually absent in the drug; carpels two; styles exserted, stigmas broad and hairy with prominent papillæ; fruit an ovoid akene about 2 mm. in diameter, enclosed by the remains of the calyx. The staminate flowers are greenish-yellow, with about twenty fertile stamens. Odor slight; taste bitter.

N. F. Preparation—Infusum Brayeræ.

History—Bruce and other African travelers had described the tree which yields this drug but it was not used in Europe until a French physician named Brayer observed the effect of the drug as a tenifuge, when employed by a traveler who had been to Abyssinia. Brayer sent some of the drug to Kunth, the German botanist, who named the tree *Brayera anthelmintica;* hence the Latin name Brayera.

Uses—It is used as an anthelmintic. Dose, one-half ounce (15 Gm.).

CASCARA AMARGA. N. F. Cascara Amarga

[**Cascar. Amarg.**—Honduras Bark]

Cascara Amarga is the dried bark of an undetermined species of *Picramnia* (Fam. *Simarubaceæ*).

Cascara Amarga contains not more than 2 per cent of foreign organic matter.

Description and Tests—(See the N. F. V.)

Preparations—Fluidextractum Trifolii Compositum, Syrupus Trifolii Compositus.

Uses—A bitter tonic said to have specific alterative properties. *Dose*, 15 grains (1 Gm.).

CAULOPHYLLUM. N. F. Caulophyllum

[**Cauloph.**—Blue Cohosh, Papoose Root, Squaw Root]

Caulophyllum is the dried rhizome and root of *Caulophyllum thalictroides* (Linné) Michaux (Fam. *Berberidaceæ*).

Caulophyllum contains not more than 3 per cent of foreign organic matter and yields not more than 4 per cent of acid-insoluble ash.

It contains a glucoside, *leontin*, also said to contain an alkaloid, *caulophylline*, resin, starch, etc.

Description—Rhizome of horizontal growth, from 7 to 25 cm. in length and from 5 to 15 mm. in thickness, much branched, slightly compressed from above, bearing large cup-shaped stem scars on the upper surface, underneath a tangled or matted mass of long, curved, thin, tough roots which frequently conceal the rhizome; both rhizome and roots of a grayish or yellowish-gray color; fracture tough and woody. Odorless but sternutatory; taste bitter-sweet and acrid.

N. F. Preparation—Fluidextractum Caulophylli.

Uses—It is used as an antispasmodic and emmenagogue. Dose, eight grains (0.5 Gm.).

CENTAURIUM. N. F. Centaury

[Centaur.]

Centaury is the dried flowering herb of *Erythræa Centaurium* (Linné) Persoon (Fam. *Gentianaceæ*).

Centaury contains not more than 3 per cent of foreign organic matter.

It contains a bitter glucoside similar to those in gentian and chirata.

Description—Glabrous, from 1.5 to 5 dm. in height, much branched from the base, but little branched, if at all, from above; stems slender, sharply angled or narrowly winged, sparsely leafy; leaves opposite, entire, mostly three-nerved, sessile, those at the base obovate and obtuse, from 2 to 5 cm. in length, their base narrowed and petiole-like, those of above gradually changing to oval, then ovate or even lance-linear, acute; flowers in a terminal and at length compound cyme, rose-colored; calyx from 5 to 7 mm. in length, deeply five-parted, the tube short, sharply angled, lobes linear-attenuate with a sharp midrib; corolla tube nearly twice the length of the calyx, slender, the limb from 10 to 15 mm. in breadth, its lobes broadly oblong or oval; stamens five, exserted, bright-yellow, their anthers twisted when old; pistil two-carpelled. Odor faint but characteristic; taste persistently bitter.

For further description see the U. S. P. X.

N. F. Preparation—Tinctura Amara.

Uses—It is a bitter tonic. Dose, thirty grains (2 Gm.).

CHIONANTHUS. N. F. Chionanthus

[Chionanth.—Fringe Tree Bark]

Chionanthus is the dried bark of the root of *Chionanthus virginica* Linné (Fam. *Oleaceæ*).

Chionanthus contains not more than 5 per cent of wood and other foreign organic matter. It yields to 70 per cent of alcohol not less than 25 per cent of non-volatile extractive.

It contains a bitter principle and probably saponin.

Description—Usually in transversely curved pieces, occasionally in single quills from 1 to 10 cm. in length; bark from 2 to 10 mm. in thickness; heavy, some pieces of the whole drug sinking when thrown into water; outer surface usually reddish-brown, occasionally grayish-brown, with few transverse wrinkles, whitish cork patches and root scars; inner surface yellowish-brown, more or less striate and undulate; fracture short, hard, and coarsely granular due to projecting groups of stone cells: the broken surface of a light yellowish-white color. Odor characteristic; taste bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Chionanthi.

Uses—It has been used as a diuretic in hepatic and syphilitic disorders.

CHIRATA. N. F. Chirata

[Chirat.]

Chirata is the dried plant of *Swertia Chirayita* (Roxburgh) Lyons (Fam. *Gentianaceæ*). It contains a bitter glucoside, *chiratin*, $C_{26}H_{48}O_{15}$, and a bitter principle, $C_{13}H_{20}O_{10}$.

Chirata contains not more than 3 per cent of foreign organic matter.

Description—Smooth, root simple, about 7 mm. in thickness near the crown stem, about 1 M. in length, externally yellowish- or purplish-brown; cylindrical near the base, quadrangular and slightly winged above, with numerous opposite, ascending branches; wood yellowish, thin, enclosing usually a large yellowish easily separable pith; leaves opposite, sessile, ovate-lanceolate, entire, five-nerved, about 6 cm. in length; flowers numerous, panicled, small, with a four-lobed calyx and corolla, capsule ovoid, acute, one-celled, many seeded. Odor slight; taste intensely bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Chiratæ.

Uses—It is used as a bitter tonic. Dose, fifteen grains (1 Gm.).

COCILLANA. N. F. Cocillana

[Cocillan.—Grape Bark]

Cocillana is the dried bark of *Guarea Rusbyi* (Britton) Rusby (Fam. *Meliaceæ*).

Cocillana contains not more than 5 per cent of wood or other foreign organic matter.

It contains resins and an active principle claimed by some to be an alkaloid, by others to be a glucoside.

Description—In flat or curved pieces of variable size and from 3 to 5 mm. in thickness; outer surface shallowly or deeply fissured, according to age and thickness, gray-brown, often ashy-gray

from lichen growths, or of a deeper brown where the cork has been removed; inner surface of medium brown color, strongly and coarsely longitudinally striate, the striæ straight or wavy; inner bark much thicker that the outer, its fracture coarsely splintery-fibrous. Odor characteristic; taste slightly astringent, peculiar and slightly nauseous.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Cocillanæ.

Uses—It is used as an expectorant; similar to ipecac in many respects. Dose, fifteen grains (1 Gm.).

CONDURANGO. N. F. Condurango

[Conduran.]

Condurango is the dried bark of *Marsdenia Condurango* (Triana) Nichols (Fam. *Asclepiadaceæ*).

Condurango contains not more than 2 per cent of wood or other foreign organic matter.

It contains resin, tannin, and a bitter glucoside, *condurangin*. *Conduransterin*, cinnamic acid, and a minute quantity of an alkaloid are also said to be present.

Description—In quills or transversely curved pieces, usually from 4 to 13.5 cm. in length; bark 1 to 6 mm. in thickness; outer surface light grayish-brown to dark brown, nearly smooth and with numerous lenticels, or more or less scaly and considerably roughened; the scales soft, occasionally with brownish-black apothecia of a fungus; inner surface grayish-white or light brown, longitudinally striate; fracture short-fibrous and granular. Odor slightly aromatic, especially marked in the fresh drug; taste bitter and aromatic.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Condurango.

Uses—It is used as an alterative and stomachic. Dose, one drachm (4 Gm.).

CONVALLARIÆ RADIX. N. F. Convallaria Root

[Conval. Rad.—Lily-of-the-Valley Root]

Convalleria Root consists of the dried rhizome and roots of *Convallaria majalis* Linné (Fam. *Liliaceæ*).

Convalleria Root contains not more than 5 per cent of leaves or other foreign organic matter and yields not more than 6 per cent of acid-insoluble ash.

This drug contains *convallarin*, a glucoside, which is split into *convallaretin* and glucose by the action of dilute acids; it also contains another glucoside, *convallamarin* ($C_{23}H_{44}O_{12}$), which is the active principle. The fluidextract is the best preparation.

Description—Rhizome horizontal, elongated, usually branched, cylindrical, variable in length, from 1 to 3 mm. in diameter; externally yellowish-white or pale brown, with a few circular stem scars, and from the under and side portions at the nodes usually arise from three to five thin, tortuous, dark brown, branching roots; fracture short or fibrous; internally whitish. Odor faint; taste sweetish, becoming bitter and acrid.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Convallariæ Radicis.

Uses—Convallaria is a cardiac stimulant, and is often used in place of digitalis. Dose, eight grains (0.5 Gm.).

CORNUS. N. F. Cornus

[Dogwood Bark]

Cornus is the dried root bark of *Cornus florida* Linné (Fam. *Cornaceæ*).

Cornus contains not more than 5 per cent of adhering wood or more than 2 per cent of other foreign organic matter.

It contains a bitter principle, *cornin*, or *cornic acid*, resin, fixed oil, tannin, etc.

Description—In irregular, chip-like pieces, or portions of quills, usually less than 5 cm. in length and from 1 to 4 mm. in thickness; externally of a dingy-brown color, lightly fissured and thinly scaly, or reddish where the corky layer has been removed; inner surface varying from pinkish-brown to red-purple, usually harsh to the touch from numerous short striæ; fracture short, the surface whitish with yellow striæ, except the inner layer, which is light purple. Odor slight; taste bitter and astringent.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Corni.

Uses—It is a mild astringent and stomachic; formerly it was believed to act as an antiperiodic. Dose, thirty grains (2 Gm.).

CROCUS. N. F. Crocus

[Saffron]

Saffron is the stigma of *Crocus sativus* Linné (Fam. *Iridaceæ*).

Saffron contains not more than 10 per cent of the yellow styles or more than 2 per cent of other foreign matter and yields not more than 7.5 per cent of total ash.

It contains a bitter principle, *picro-crosin*, or *saffron-bitter*, $C_{38}H_{66}O_{17}$, and *crocin*, $C_{44}H_{70}O_{28}$, a glucoside. It also contains volatile oil.

Description—Stigmas 3, united or separate, attached to the summit of the style; usually about 25 mm. in length, cornucopia-shaped, of a dark, rich red color, the margin dentate or fimbriate; styles about 10 mm. in length, more or less cylindrical, solid, yellowish. Odor strong, peculiarly aromatic; taste bitterish, aromatic. When chewed it colors the saliva orange-yellow.

For further description see the N. F. V.

N. F. Preparations—Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe; Tinctura Croci; Tinctura Opii Crocata.

Uses—It has been used as an anodyne, antispasmodic, and emmenagogue, but is of little value. It is also used as a coloring agent.

FARFARA. N. F. Coltsfoot

[Coltsfoot Leaves, Tussilago Leaves]

Coltsfoot is the dried leaf of *Tussilago Farfara* Linné (Fam. *Compositæ*).

Coltsfoot contains not more than 3 per cent of foreign organic matter and yields not more than 4 per cent of acid-insoluble ash.

It contains a bitter glucoside, tannin, resin, gum, etc.

Description—Petioles long, pubescent; blades very brittle, nearly orbicular or broadly ovate-reniform, from 8 to 15 cm. in length and nearly as broad, deeply cordate at the base, angulately lobed and dentate with red-brown teeth, palmately five- to nine-veined; young leaves white floccose all over, the older leaves with upper surfaces dark green and nearly smooth, the younger densely white floccose. Odor indistinct; taste mucilaginous, faintly herbaceous, bitter.

N. F. Preparation—Species Pectorales.

Uses—It is used as a demulcent and tonic. Dose, one drachm (4 Gm.).

GOSSYPII CORTEX. N. F. Cotton Root Bark

[Gossyp. Cort.]

Cotton Root Bark is the recently-gathered air-dried bark of the root of one or more of the cultivated varieties of *Gossypium herbaceum* Linné, or of other species of *Gossypium* (Fam. *Malvaceæ*).

Cotton Root Bark contains not more than 5 per cent of wood or other foreign organic matter.

It contains a yellow resin, *chromogene*, which becomes red on exposure to air, also fixed oil, tannin, starch, sugar, etc.

Description—In flexible bands or quilled pieces, attaining a length of 30 cm. and a thickness of about 1 mm.; outer surface orange-brown, smooth, slightly wrinkled, with small circular lenticels, the outer corky layer frequently exfoliated and showing the more or less fissured and fibrous middle bark; inner surface light brown, longitudinally striate; fracture tough, fibrous, the inner bark readily separable into fibrous layers. Odor slight; taste very slightly acrid.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Gossypii Corticis.

Uses—It is used as an emmenagogue. The fresh bark, which is now official, is said to be much more active than old bark. Dose, thirty grains (2 Gm.).

HELONIAS. N. F. Helonias

[Helon.—False Unicorn]

Helonias is the dried rhizome and roots of *Chamælirium luteum* (Linné) A. Gray (Fam. *Liliaceæ*).

Helonias contains not more than 5 per cent of foreign organic matter.

It contains about 10 per cent of an amorphous glucoside, *chamælirin*, soluble in alcohol and water. With acids this yields *chamæliretin*.

Description—Rhizome upright, or oblique, nearly cylindrical, from 0.5 to 3 cm. in length and about 1 cm. in diameter; externally grayish-brown, annulate from scars of bud-scales; upper portion with leaf bases enclosing a small bud; oblique rhizomes with a few stem scars about 0.5 mm. in diameter; lower portion with numerous whitish or pale yellowish, nearly straight or slightly curved wiry roots, from 5 to 8 cm. in length; fracture hard and horny; internally grayish-yellow, cortex from 3 to 4 mm. in thickness, central cylinder with three or four circles of small, nearly circular fibro-vascular bundles. Odor distinctive; taste bitter, slightly astringent.

For further description see the N. F. V.

N. F. Preparations—Elixir Aletridis Compositum; Elixir Heloniadis Compositum; Fluidextractum Heloniadis.

Uses—It is used in dropsy and also as a vermifuge in tape worm. Dose, thirty grains (2 Gm.).

HYDRANGEA. N. F. Hydrangea

[**Hydrang.**—Seven-Barks]

Hydrangea consists of the dried rhizome and roots of *Hydrangea arborescens* Linné (Fam. *Saxifragaceæ*).

Hydrangea contains not more than 3 per cent of foreign organic matter.

It contains about 1 per cent of a glucoside, *hydrangin*, said to have the formula $C_{34}H_{25}O_{11}$.

Description—Rhizome cylindrical, usually cut into pieces from 3 to 10 cm. in length and from 3 to 20 mm. in diameter; externally light brown to yellowish-brown with a pinkish tinge, longitudinally wrinkled, marked by few elliptical lenticels and occasional prominent buds, short branches or stem scars; from the lower surface arise a few coarse fibrous roots; fracture tough, splintery; internally yellowish-white or light brown, bark thin, easily separable from the distinctly radiate wood which surrounds a prominent whitish pith. Roots attaining a length of 25 cm. and a thickness of 2 mm., irregularly bent and branching, otherwise resembling the rhizome with the exception of the pith being absent. Inodorous; taste sweetish, becoming slightly acrid.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Hydrangeæ.

Uses—It is used as a diuretic. Dose, thirty grains (2 Gm.).

LAPPA. N. F. Lappa

[**Lapp.**—Burdock Root]

Lappa is the dried first year root of *Arctium Lappa* Linné, or of *Arctium minus* Bernhardi (Fam. *Compositæ*).

Lappa contains not more than 5 per cent of its leaf bases or more than 2 per cent of other foreign organic matter.

Description—Nearly simple, fusiform, of variable length, from 5 to 20 mm. in diameter near the crown; frequently split or in broken pieces, externally grayish-brown, longitudinally wrinkled, the crown somewhat annulate, sometimes surmounted by a woolly tuft of leaf remains; fracture somewhat horny; a dark cambium separating the thick brownish bark from the yellowish porous and radiate wood, centrally hollow or containing a white, pith-like tissue. Odor slight; taste mucilaginous, sweetish, and slightly bitter.

For further description see the U. S. P. X.

N. F. Preparation—Fluidextractum Lappæ.

Uses—It is used as a diuretic and alterative especially in chronic skin diseases. Dose, thirty grains (2 Gm.).

MELILOTUS. N. F. Melilot

[**Melilot.**—Yellow Melilot, Yellow Sweet Clover]

Melilot consists of the dried leaf and flowering top of *Melilotus officinalis* (Linné) Lamarck (Fam. *Leguminosæ*).

Melilot contains not more than 3 per cent of its stems over 3 mm. in diameter or other foreign organic matter.

It contains *cumarin* and has a pungent, bitterish taste.

Description—Stems mostly less than 3 dm. in length, slender, straight, mostly simple, often leafy below, terminating in long, slender racemes, the younger portions very finely pubescent; leaves glabrous or nearly so; petiolate, trifoliate, stipulate, the stipules subulate, entire, the leaflets from 1 to 3 cm. in length, varying from narrowly oblong to oval or occasionally broader above the middle, rounded, truncate, or slightly notched at the summit, sharply serrate; racemes 1 dm. or less in length, many flowered, the flowers yellow, from 5 to 6 mm. in length; calyx bell-shaped,

the fine nearly equal lobes shorter than the tube, corolla papilionaceous, the keel shorter than the other petals, which are about equal; legumes reflexed, from 2.5 to 3.5 mm. in length, obovate wrinkled, one-seeded. Odor aromatic, tonka-like; taste sweetish, slightly pungent and bitter.

For further description see the N. F. V.

N. F. Preparation—Species Emollientes.

Uses—It is used in diarrhea, dysmenorrhea, and rheumatism, also, in the form of cigarettes, for asthma and bronchitis, but is probably inert.

PHYTOLACCA. N. F. Phytolacca

[**Phytolac.**—Poke Root]

Phytolacca is the dried root of *Phytolacca americana* Linné (Fam. *Phytolaccaceæ*).

Phytolacca contains not more than 5 per cent of its stem bases or more than 2 per cent of other foreign organic matter.

It contains an amorphous, bitter, and acrid glucosidal substance, similar to saponin, which is the most active substance. There is present also a small amount of an alkaloid, *phytolaccine*, and *phytolaccic acid*.

Description—Cylindrical, somewhat tapering, sparingly branched from 3 to 7 cm. in thickness, mostly in transverse or longitudinal slices; externally yellowish-brown, finely longitudinally or spirally wrinkled and thickly annulate with lighter colored, low ridges; fracture fibrous, characterized by alternating layers of fibro-vascular tissue and parenchyma, the layers of the latter being much retracted. Odor slight; taste sweetish, afterwards highly acrid.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Phytolaccæ.

Uses—It is used as an alterative, in doses of two grains (0.125 Gm.), and as an emetic, in doses of fifteen grains (1 Gm.).

TRIFOLIUM. N. F. Trifolium

[**Trifol.**—Red Clover Blossoms]

Trifolium is the dried inflorescence of *Trifolium pratense* Linné (Fam. *Leguminosæ*).

Trifolium contains not more than 2 per cent of foreign organic matter.

It contains sugars and a bitter principle but none of the ingredients are very active.

Description—Heads ovoid with rounded summit, mostly from 12 to 25 mm. in length and breadth, shriveled, purplish and more or less brown from drying, consisting of many small papilionaceous flowers, crowded together and clothed at the base with broad, pointed ciliate stipules of a pale green color with darker veins, and which may or may not be accompanied by diminutive trifoliate leaves. Flowers from 12 to 15 mm. in length, longer than the four nearly equal teeth and shorter than the narrower fifth tooth; calyx-teeth subulate, tapering; petals united into a tube below, the standard longer than the wings but when recurved appearing shorter; stamens diadelphous (nine and one); style slender. Odor faintly aromatic and somewhat tea-like; taste sweetish, then slightly bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Trifolii.

Uses—It is used as an expectorant and alterative. Dose, one drachm (4 Gm.).

QUILLAJA. N. F. Quillaja

[**Quillaj.**—Soap-tree Bark]

Quillaja is the dried inner bark of *Quillaja Saponaria* Molina (Fam. *Rosaceæ*).

Quillaja contains not more than 5 per cent of the outer bark and not more than 1 per cent of foreign organic matter.

This South American bark owes its activity to a peculiar principle, *saponin*, $C_{32}H_{54}O_{18}$, a glucoside, splitting upon heating with dilute acid into *sapogenin* and sugar. Saponin is a sternutatory, white powder, soluble in alcohol and hot water; its aqueous solution froths when agitated, like soapsuds; it is found in several other drugs. Quillaja also contains calcium oxalate and calcium sulphate.

Description—In flat pieces of variable lengths, from 3 to 8 mm. in thickness, or in small chips; outer surface brownish-white, often with small patches of cork attached, otherwise nearly smooth; inner surface yellowish-white, nearly smooth, with occasional circular depressions, conical projections of transverse channels; fracture uneven and strongly fibrous, the laminæ oblique to each other. Odor slight; taste acrid. For further description see the N. F. IV.

N. F. Preparations—Liquor Picis Carbonis; Tinctura Quillajæ.

Uses—It is used principally for cleansing silk; in pharmacy it is used as an emulsifying agent, but, as saponin is not an inert substance, it is unfitted for this purpose. It is sometimes used in medicine, as a nauseating expectorant. Dose, three grains (0.2 Gm.).

TARAXACUM. N. F. Taraxacum

[Tarax.—Dandelion]

Taraxacum consists of the dried rhizome and roots of *Leontodon Taraxacum* Linné (Fam. *Compositæ*). Taraxacum contains not more than 2 per cent of foreign organic matter and yields not more than 4 per cent of acid-insoluble ash. Preserve Taraxacum in tightly-closed containers.

Taraxacum owes its bitterness to taraxacin, an acrid crystalline principle, soluble in alcohol and water. It also contains pectin, sugar, resin, gum, etc.

Description—Cylindrical or somewhat flattened, gradually tapering, usually in broken pieces from 6 to 15 cm. in length and from 5 to 15 mm. in thickness; externally brown or blackish-brown, longitudinally wrinkled, having numerous root and rootlet-scars; crown simple or branched with numerous leaf-bases showing annulate markings. Odor slight or inodorous; taste bitter.

For further description see the N. F. V.

N. F. Preparations—Elixir Gentianæ Glycerinatum (from Fluidextract); Elixir Taraxaci Compositum (from Fluidextract); Extractum Taraxaci; Fluidextractum Taraxaci.

Uses—It is used as a cholagogue and as a diuretic. Dose, two drachms (8 Gm.).

Unofficial Drugs Containing Glucosides or Bitter Principles

Arbutin, N. N. R.	A glucoside ($C_{12}H_{16}O_7.\frac{1}{2}H_2O$) occurring in the leaves of *Arctostaphylos uva ursi*, and other genera of the Fam. *Ericaceæ*. A urinary antiseptic and diuretic. Dose, 3 to 8 grains (0.2 to 0.5 Gm.) three or four times a day. Merck and Co., distributors
Azedarach Azedarach	The bark of the root of *Melia Azadirachta*. It contains a resinous principle, and is used as an emetic and anthelmintic, in doses of fifteen to thirty grains (1 to 2 Gm.)
Cassia Marilandica American Senna	Cathartic. Used in the form of infusion
Chamælirium Starwort	The rhizome of *C. luteum* and other species. It contains about 8 per cent of the glucoside *chamælirin*
Convallaria Flowers (N. F. IV) Lily-of-the-valley Flowers	The dried inflorescence of *Convallaria majalis* Linné (Fam. *Liliaceæ*). Its other constituents are similar to those in the root but in smaller amounts (see page 1075). A cardiac stimulant; dose, eight grains (0.5 Gm.)
Coronilla Scorpioides	Cardiac stimulant, diuretic
Frasera American Columbo	The root of *F. Walteri*, indigenous to the United States. It contains *gentisic acid* and *gentiopicrin*
Gillenia Gillenia	The rhizome of *G. trifoliata* and others, indigenous to the United States. It contains the bitter principle *gillenin*, resin, tannin, etc.
Gratiola Hedge Hyssop	From *G. officinalis*, indigenous to Southern Europe. It contains a bitter glucoside, *gratiolin*, etc.
Hedera Helix Ivy	Contains a glucoside, and hederic and tannic acids. Dose, twenty grains (1.3 Gm.) or more, dried and powdered, given in the atrophy of children
Helleborus Black Hellebore	The rhizome of *H. niger*, grown in Europe. It contains a crystalline glucoside *helleborin*, $C_{26}H_{44}O_{15}$
Ilex Holly	The leaves of different species of *Ilex*, indigenous to the United States. It contains *ilixanthin*, $C_{17}H_{22}O_{11}$, and *ilicic acid*
Ledum Marsh Tea	The leaves of *L. palustre*, grown in North America. It contains the glucoside *ericolin*, $C_{34}H_{56}O_{21}$; also about 1 per cent of volatile oil
Ligustrum Privet	The leaves of *L. vulgare*, indigenous to Southern Europe. It contains *ligustrin*, etc.
Liriodendron Tulip Tree Bark	The bark of *L. tulipifera*, found in the Northern United States. It contains *liriodendrin*, which occurs in white prisms
Lupinus Albus Lupin	Contains a glucoside, *lupinin*, $C_{29}H_{32}O_{16}$. The seeds are used as an anthelmintic, diuretic, and emmenagogue
Megarrhiza Californica (Man Root)	It contains a resinous substance called *megarrhizitin*, and a glucoside called *megarrhin*, possessing mydriatic properties
Menyanthes (N. F. IV) Buckbean Marsh Trefoil	The dried leaves of *Menyanthes trifoliata* Linné (Fam. *Gentianaceæ*). The chief constituent is the glucoside *menyanthin*, $C_{30}H_{46}O_{14}$; *meliatin* is also said to be present. It is used as a tonic. Dose, fifteen grains (1 Gm.)
Panax Ginseng	The root of *P. quinquefolium*, found in North America. It contains *panaquilon*, $C_{12}H_{25}O_9$
Phlorhizin, N. N. R. Phlorizin	A glucoside from the root of the apple, pear, cherry, etc., $C_{21}H_{24}O_{10}.2H_2O$. It has been used in malaria but is not recommended. Used to test the functional activity of the kidney. Dose, ¼ gr. (0.005 Gm.) in 15 min. (1 cc.) 0.5 per cent solution of sodium carbonate, by injection, for kidney test. Merck and Co., distributors
Picrotoxinum, $C_{30}H_{34}O_{13}$ Picrotoxin. (U. S. P. 1890)	A neutral principle obtained from the seed of *Anamirta paniculata* Colebrook (Fam. *Menispermaceæ*). Odorless, bitter, colorless crystals, or a microcrystalline powder, used as a tonic and antispasmodic, in doses of one-sixtieth grain (0.001 Gm.). Very poisonous in large doses
Piscidia Erythrina Jamaica Dogwood	Narcotic, anodyne. Dose of fluidextract is one fluidrachm (4 cc.), to be increased carefully
Prinos Black Alder	The bark of *Prinos verticillatus*. It contains a bitter principle. It is a tonic, astringent, and alterative
Rhus Toxicodendron Poison Ivy (U. S. P. 1890)	The fresh leaves of *Rhus radicans* Linné. Fam. *Anacardiaceæ*. It contains *toxicodendric acid*, fixed oil, etc. It is toxic, irritant, and rubefacient. Dose, five grains (0.32 Gm.)

Unofficial Drugs Containing Glucosides or Bitter Principles—*Continued*

Ruta Rue	The leaves of *R. graveolens*, which grows in Southern Europe. It contains a volatile oil and *rutin*, $C_{25}H_{28}O_{15}$, which occurs in needle-shaped crystals. Emmenagogue. Dose, fifteen to thirty grains (1 to 2 Gm.), two or three times a day, preferably given in infusion
Sabbatia American Centaury	A simple bitter. Dose, one drachm (4 Gm.), given in the form of fluidextract or decoction
Salix Willow	The bark of *Salix alba*, and of other species of Salix. It contains a glucoside, *salicin*, ($C_{13}H_{18}O_7$).
Saponaria Officinalis Soapwort Bouncing Bet	Contains a glucoside, saponin
Simaruba Simaruba	The bark of the root of *S. officinalis*, grown in South America. It contains a bitter principle, a volatile oil, etc. Tonic. Dose, from twenty to sixty grains (1.3 to 4 Gm.), best given in infusion
Taxus Yew	From *Taxus baccata*, grown in Asia. It contains volatile oil, *taxina*, etc.
Ustilago Corn Smut	From *Zea Mays*. It contains a principle analogous to sclerotic acid. Used as a parturient. Dose, fifteen to thirty grains (1 to 2 Gm.)
Verbena (N. F. IV) Blue Vervain	The dried over-ground portion of *Verbena hastata* Linné (Fam. *Verbenaceæ*), collected when flowering. It is said to contain a bitter glucoside, but has not been carefully investigated. It is a weak expectorant and diaphoretic in doses of fifteen grains (1 Gm.)
Viola Tricolor Pansy	The flowering herb of *Viola tricolor*. It contains a bitter principle, salicylic acid, etc. It is expectorant and alterative, in doses of fifteen to forty grains (1 to 2.6 Gm.)
White Ash Bark (N. F. IV)	The dried bark of *Fraxinus americana* Linné (Fam. *Oleaceæ*), and probably of other species of *Fraxinus* deprived of the corky layer. It contains a bitter glucoside, *fraxin*, $C_{16}H_{18}O_{10}$, and also *fraxetin*, $C_{10}H_8O_5$, tannin, etc. It is a bitter tonic and astringent. Dose, thirty grains (2 Gm.)

Drugs Containing Cathartic Principles, and their Preparations

ALOE. U.S. Aloe

Aloe is the inspissated juice of the leaves of *Aloe Perryi* Baker, known in commerce as Socotrine Aloe; of *Aloe vera* Linné, known in commerce as Curaçao Aloe; or of *Aloe ferox* Miller, known in commerce as Cape Aloe (Fam. *Liliaceæ*).

Aloe yields not more than 4 per cent of ash, not more than 10 per cent of moisture, and not less than 50 per cent of water-soluble extractive.

Aloe contains *aloin*, *emodin*, a trace of volatile oil, and a substance which has been improperly called resin. The aloin present in Socotrine aloe is *socaloin*, $C_{15}H_{16}O_7$. This may be distinguished from *nataloin* and *barbaloin* by tests found in the U. S. P. text.

Description—*Socotrine Aloe*—In yellowish-brown to blackish-brown, opaque, smooth and glistening masses; fractured surface somewhat conchoidal; odor characteristic.

Curaçao Aloe—In orange to blackish-brown, opaque masses; fractured surface uneven, waxy, somewhat resinous; odor characteristic, disagreeable.

Cape Aloe—In reddish-brown masses, usually covered with a yellowish powder, or in thin, transparent fragments, of a reddish-brown color; fracture smooth and glassy; odor characteristic, sour and disagreeable.

The taste of each variety of Aloe is nauseous and very bitter.

Tests for Identity—Powdered Aloe dissolves in nitric acid with effervescence, Socotrine Aloe forming a yellowish to reddish-brown solution; Curaçao Aloe, a deep red solution; Cape Aloe a reddish-brown solution, changing to purplish-brown and finally to greenish.

Intimately mix in a flask or bottle about 1 Gm. of powdered Aloe, accurately weighed, with 25 cc. of cold water, shake occasionally during two hours, transfer to a filter, tared after it has been dried over sulphuric acid, and wash with sufficient cold water to make the filtrate measure 100 cc.: the residue on the filter after drying over sulphuric acid should not exceed 50 per cent of the weight of powdered Aloe taken. The color of the filtrate, viewed in the bulb of a 100 cc. volumetric flask, is light yellowish-brown with Socotrine Aloe, reddish-brown with Curaçao Aloe, and yellowish with Cape Aloe. The filtrate darkens upon standing.

To 5 cc. of the filtrate mentioned above, add 2 cc. of nitric acid: the mixture is of a yellowish to yellowish-brown color with Socotrine Aloe; a deep red color with Curaçao Aloe; a reddish-brown color, changing to vivid green, with Cape Aloe.

To 5 cc. of the filtrate mentioned above, add 45 cc. of water and 20 cc. of sodium borate solution (1 in 20): a greenish fluorescence results and, upon standing, the liquid acquires a brownish color.

To 10 cc. of the filtrate mentioned above, add 90 cc. of water and shake with 10 cc. of benzene: upon separating the benzene layer, and adding to it 5 cc. of ammonia T.S., a permanent, deep rose color is produced in the lower layer.

For further description see the U. S. P. X.

Assay—Proceed as directed under water-soluble extractive, page 1523.

No aloin assay was adopted by the U. S. P. X, as it was found that the available methods would not estimate the aloin in Cape Aloes which was an important commercial variety. The following assay method was suggested by J. P. Snyder, and is used in estimating the value of aloes for the manufacture of aloin.

Assay of Aloe for Aloin

A sample of fifty grams of Aloe is mixed with about 300 cc. of hot water and 2 cc. of HCl and allowed to boil until solution results. Let stand until cool and decant the supernatant liquid from the separated resins completely. To the liquid add 50 cc. of strong ammonia, then add slowly with stirring, a solution of 15 Gm. of calcium chloride in 30 cc. of water. Let stand for fifteen or twenty minutes in order to insure complete precipitation. Then transfer to a 3-inch Buchner funnel and drain as dry as possible by using vacuum. Remove the cake from the funnel by tapping the sides and place between two layers of heavy filter paper, using six or eight sheets of paper on each side of the cake. Place in a letter press, or other convenient form of hand press and apply pressure until no more moisture can be squeezed from the cake. Separate the cake completely from the filter paper and place in an evaporating dish. Now break the cake up thoroughly with a glass rod and add HCl slowly, a few drops at a time until there is an excess of acid. Allow the aloin to crystallize completely, which usually requires about 30 minutes. Transfer to a Buchner funnel again and wash three or four times with a saturated aqueous solution of Aloin. Drain as dry as possible, squeeze out all moisture possible with a press as before and transfer the cake of moist aloin to a weighed dish. Dry at a low heat, not over 50° C. for several hours and weigh. This determination gives results in terms of dry aloin. Upon standing, this Aloin will take up from 2 to 3 per cent of moisture.

U. S. P. Preparations—Extractum Colocynthidis Compositum; Pilulæ Aloes; Tinctura Aloes; Tinctura Benzoini Composita.

N. F. Preparations—Pilulæ Aloes et Asafœtidæ; Pilulæ Aloes et Ferri; Pilulæ Aloes et Mastiches; Pilulæ Aloes et Myrrhæ; Pilulæ Aloes et Podophylli Compositæ; Pilulæ Aloes Hydrargyri et Scammonii Compositæ (from Tincture of Aloes and Myrrh); Pilulæ Antiperiodicæ (from Extract); Pilulæ Ferri, Quininæ, Aloes et Nucis Vomicæ; Pulvis Aloes et Canellæ; Tinctura Aloes et Myrrhæ; Tinctura Antiperiodica (from Extract).

History—This drug was mentioned by Dioscorides in the first century of the Christian Era. He advised its use in doses of from one to three drachms, especially for *urbani et literatim cupidi* (city men and men of letters), *i.e.*, those of sedentary habits. It was an ingredient in the ancient *hieras* (see Pulvis Aloes et Canellæ) and in many compound pills and other laxative preparations.

Uses—Aloe is used as a cathartic and emmenagogue. Dose, four to twenty grains (0.25 to 1.3 Gm.).

ALOINUM. U. S. Aloin

[Aloin.]

A pentoside or mixture of pentosides obtained from aloe. It varies in chemical composition and in physical and chemical properties according to the variety of aloe from which it is obtained.

Aloin is usually made by dissolving 1 part of Curaçao or Barbadoes Aloes in 10 parts of boiling water acidulated with hydrochloric acid, and, after cooling, the liquid is decanted from the resinous matter, evaporated to about 2 parts, and set aside for two weeks for crystals to form. The crystals are washed with acetic ether and dried. Socaloin and nataloin are not often found in commerce, as the aloes from which they would be prepared are scarce and the products would be expensive.

Description and Physical Properties—A lemon-yellow to dark yellow microcrystalline powder or minute crystals. It is odorless, or has a slight odor of aloe. The taste is intensely bitter. Aloin darkens on exposure to light and air.

Aloin is soluble in water, alcohol, and acetone, the degree of solubility varying with its composition. It is also soluble in ammonia water and in solutions of alkali hydroxide, forming red solutions (or yellow solutions that soon become red) having a green fluorescence. It is slightly soluble in ether.

Tests for Identity—A saturated aqueous solution of Aloin is yellow, changing to brown on standing. The solution is neutral or not more than faintly acid to litmus paper.

Aloin is rapidly decomposed when added to alkaline solutions; when mixed with acid solutions, decomposition is slower.

A drop of ferric chloride T.S. added to an alcoholic solution of Aloin produces a brownish-green color.

Tests for Purity—Ash: not more than 0.5 per cent.

Shake 1 Gm. of Aloin with 10 cc. of benzene for one minute and filter; the filtrate imparts not more than a faint pink color to an equal volume of 5 per cent ammonia water when shaken with it (*emodin*).

Dissolve 1 Gm. of Aloin, accurately weighed, in 120 cc. of distilled water at 25° C. by shaking frequently during two hours. Collect the insoluble residue, if any, on a filter, or a Gooch crucible, tared after it has been dried at 100° C., and wash the residue with 25 cc. of distilled water: this residue when dried at 100° C. does not exceed 1.5 per cent.

Preserve in well-closed containers, protected from light.

N. F. Preparations—Pilulæ Aloini Compositæ; Pilulæ Aloini, Strychninæ et Belladonnæ; Pilulæ Aloini, Strychninæ et Belladonnæ Compositæ; Pilulæ Laxativæ Compositæ.

Uses—Aloin is used as a cathartic, in doses of two grains (0.125 Gm.). The laxative dose is one-quarter to one grain (0.015 to 0.06 Gm.).

CASCARA SAGRADA. U. S. Cascara Sagrada

[**Casc. Sagr.**—RHAMNUS PURSHIANA]

Cascara Sagrada is the dried bark of *Rhamnus Purshiana* De Candolle (Fam. *Rhamnaceæ*).

NOTE—Cascara Sagrada should be collected at least one year before being used for making medicinal preparations.

The following review of the chemistry of cascara sagrada and other cathartic drugs is abstracted from an article by L. E. Warren *J. A. Ph. A.* 1924, page 254.

Cascara belongs to the drugs known as the "anthracene purgatives", the designation indicating that the active constituents are derivatives of the hydrocarbon, anthracene. This class of drugs includes one or more species of aloe, morinda, rhamnus, rhubarb, rumex, senna, xanthoxylum, and perhaps others.

It appears to be accepted that the active constituents of this group of drugs for the most part are derivatives of hydroxymethyl anthraquinone. More work has been done on rhubarb and aloe than on the other members of the group. Consequently the knowledge of the anthraquinone purgatives has been mostly obtained from these drugs rather than from cascara. The chief constituents isolated from cascara are compounds containing emodin, 1-4-6 trihydroxy 8-methyl anthraquinone, chrysophanol 1-4 dihydroxy 8-methyl anthraquinone and emodin monoethyl ether, 1-4 dihydroxy 6-methoxy 8-methyl anthraquinone. The position of the methyl group is not known with certainty. Its presence appears to have but little pharmacologic significance. Emodin and its compounds are present in much greater proportions in cascara than are the other anthraquinones. Most of the emodin is combined. Free emodin is a relatively weak laxative.

The exact composition of the anthraquinone complexes is not known but they are believed to be glucosides and pentasides since, on hydrolysis with mineral acids, they yield glucose or pentose and anthraquinone compounds. They are believed to produce catharsis by the slow hydrolysis of the anthraquinone complex through the action of a ferment in the lower bowel. It is believed by some that this ferment is activated by the presence of mineral salts such as calcium acid phosphate. It is known that the action of emodin-bearing drugs is enhanced if they are administered with certain ferments, such as emulsin. It has recently been found by Casparis and Godelin (*Schweiz, Ap. Ztg.*, 61, 389, 1923) that rhubarb extracts if prepared in a vacuum apparatus are nearly four times as effective when tested on white mice as similar extracts prepared in the usual way. This would suggest that the action of a ferment is necessary in the pharmacologic action of the anthraquinone purgatives, such a ferment being preserved by the low temperature of the vacuum, but killed or inactivated by the high temperature of ordinary evaporations. It is admitted that no chemical assay of the anthraquinone drugs is entirely successful. The most satisfactory method is that perfected by Daels (*Bull. Acad. Roy. Med. Belg.* (4), 27,350, 1913). It consists in extracting the anthraquinones from the drug with chloroform both before and after acid hydrolysis. The total anthraquinones are weighed and the results calculated as "free" and "combined" anthraquinones. In the case of rhubarb the Daels values have been found to parallel the physiologic assay moderately well if the physiologic test be made on extracts prepared by the vacuum method.

When ground Cascara Sagrada is moistened and mixed with a hydroxide (magnesium hydroxide or calcium hydroxide preferably) the drug loses its intensely bitter taste, the acid constituents being neutralized and apparently rendered insoluble. Such treatment seems to lessen its activity.

Description—Usually in flattened or transversely curved pieces, occasionally in quills; bark from 1 to 5 mm. in thickness; outer surface dark brown or brownish-red, longitudinally ridged, with grayish or whitish lichen patches, sometimes with numerous lenticels and occasionally with moss; inner surface longitudinally striate, light yellow to dark reddish-brown or dark brown in old matured bark; fracture short with projections of bast-bundles in the inner bark; odor distinct; taste bitter and slightly acrid.

For further description see the U. S. P. X.

U. S. P. Preparations—Extractum Cascaræ Sagradæ; Fluidextractum Cascaræ Sagradæ; Fluidextractum Cascaræ Sagradæ Aromaticum.

N. F. Preparations—Elixir Cascaræ Sagradæ (from Aromatic Fluidextract); Elixir Cascaræ Sagradæ Compositum (from Aromatic Fluidextract); Fluidglyceratum Cascaræ Sagradæ; Fluidglyceratum Cascaræ Sagradæ Aromaticum; Pilulæ Aloini, Strychninæ et Belladonnæ Compositæ (from Extract); Syrupus Ficorum Compositus (from Aromatic Fluidglycerate).

Uses—Cascara Sagrada is a laxative. Dose, fifteen grains (1 Gm.).

RHEUM. U. S. Rhubarb

Rhubarb consists of the dried rhizome and roots of *Rheum officinale* Baillon or of *Rheum palmatum* Linné (Fam. *Polygonaceæ*) or other species of *Rheum* grown in China and Tibet, deprived of periderm tissues.

Rhubarb yields not less than 30 per cent of diluted alcohol-soluble extractive.

Description—In subcylindrical or flattened pieces, frequently showing a large perforation; from 5 to 17 cm. in length and from 4 to 10 cm. in diameter; outer surface yellowish-brown with lighter colored striations and occasional small patches of brown cork; more or less covered with yellowish-brown powder; hard; fracture uneven, showing stellate vascular bundles and a granular, yellowish or pinkish-brown mottled surface; odor aromatic, agreeable; taste bitter and astringent.

For further description see the U. S. P. X.

Assay—Proceed as under diluted alcohol-soluble extractive, page 1523.

U. S. P. Preparations—Extractum Rhei; Fluidextractum Rhei; Pulvis Rhei Compositus; Syrupus Rhei (from Fluidextract); Syrupus Rhei Aromaticus (from Aromatic Tincture); Tinctura Rhei; Tinctura Rhei Aromatica.

N. F. Preparations—Elixir Catharticum Compositum (from Fluidextract); Fluidglyceratum Rhei; Mistura Opii et Rhei Composita (from Tincture); Mistura Rhei Alkalina (from Fluidextract); Mistura Rhei Composita (from Fluidextract); Pilulæ Antiperiodicæ; Pilulæ Antiperiodicæ sine Aloe; Pilulæ Rhei; Pilulæ Rhei Compositæ; Pulvis Rhei et Magnesiæ Anisatus; Syrupus Sennæ Aromaticus; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe; Tinctura Rhei Aquosa; Tinctura Rhei Dulcis; Tinctura Rhei et Gentianæ.

Rhubarb contains *chrysophanic acid*, or dioxymethylanthraquinone, $C_{15}H_8O_2(OH)_2$; *emodin*, or trioxymethylanthraquinone, $C_{15}H_7O_2(OH)_3$; *rhein*, or tetraoxymethylanthraquinone, $C_{15}H_{10}O_6$; *rhabarberon*, $C_{15}H_{10}O_5$; and the resins, *erythroretin*, *phæretin*, and *aporetin*. The astringent properties of rhubarb are due to *rheotannic acid*, $C_{26}H_{26}O_{14}$; calcium oxalate is also present.

Uses—The therapeutic properties of rhubarb depend upon the valuable natural combination of its cathartic and astringent constituents. It is given in doses of ten to twenty grains (0.6 to 1.3 Gm.).

SENNA. U. S. Senna

[Senn.]

Senna consists of the dried leaflets of *Cassia Senna* Linné, known in commerce as Alexandria Senna, or of *Cassia angustifolia* Vahl, known in commerce as Tinnevelly Senna (Fam. *Leguminosæ*).

Senna contains not more than 10 per cent of its stems, and not more than 2 per cent of its pods or other foreign organic matter, and yields not more than 3 per cent of acid-insoluble ash.

Description—*Alexandria Senna*—Inequilaterally lanceolate or lance-ovate, frequently broken; from 2 to 3.5 cm. in length and from 6 to 10 mm. in width, unequal at the base, with very short, stout petioles; acutely cuspidate, entire, brittle, subcoriaceous; hairs short and somewhat appressed, few on the upper surface, more numerous on the lower surface, where they occur spreading on the midrib, especially on the lower part; color light grayish-green; odor characteristic; taste mucilaginous, slightly bitter.

Tinnevelly Senna—Usually unbroken, from 2 to 5 cm. in length, from 6 to 15 mm. in width; broadly acute at the apex, slightly hairy; light yellowish-green and otherwise resembling Alexandria Senna.

For further description see the U. S. P. X.

U. S. P. Preparations—Fluidextractum Sennæ; Pulvis Glycyrrhizæ Compositus; Syrupus Sennæ (from Fluidextract).

N. F. Preparations—Confectio Sennæ; Elixir Cascaræ Sagradæ Compositum (from Fluidextract); Elixir Catharticæ Compositum (from Fluidextract); Infusum Sennæ Compositum; Species Laxativæ; Syrupus Ficorum Compositus; Syrupus Sennæ Aromaticus.

Senna, according to Tschirch, contains *anthroglucosennin, emodin, chrysophanic acid,* isoemodin, glucosennin, sennanigrin, and sennarhamnetin. Emodin and chrysophanic acids are oxymethylanthraquinones upon which the cathartic action is believed to depend. *Cathartic acid* was formerly believed to be the chief purgative principle. When senna leaves are macerated in strong alcohol, the principles which produce griping and give odor and taste are said to be dissolved, while the purgative properties are unaffected. Water and diluted alcohol are good solvents for its virtues. It is an important ingredient in the compound powder of glycyrrhiza.

Uses—Senna is a cathartic. The dose is one to four drachms (4 to 16 Gm.), when given in infusion.

CHRYSAROBINUM. U. S. Chrysarobin

[Chrysarob.]

A mixture of neutral principles obtained from Goa powder, a substance deposited in the wood of *Vouacapoua Araroba* (Aguiar) Druce (Fam. *Leguminosæ*).

Description and Physical Properties—A brownish or orange-yellow, microcrystalline powder. It is tasteless, odorless, and irritating to the mucous membrane.

Chrysarobin is very slightly soluble in water. One Gm. dissolves in 385 cc. of alcohol, 30 cc. of benzene, 180 cc. of carbon disulphide, 13 cc. of chloroform, and in 160 cc. of ether, at 25° C.

Tests for Identity—Chrysarobin dissolves in solutions of alkali hydroxides and in sulphuric acid, producing deep red solutions. On pouring the sulphuric acid solution into water, Chrysarobin is deposited unchanged.

Mix about 0.002 Gm. of Chrysarobin with 2 drops of fuming nitric acid: a red-brown mixture is produced which becomes violet-red on the addition of a few drops of ammonia T.S. (*difference from chrysophanic acid,* which produces a yellow liquid).

Tests for Purity—Boil 0.1 Gm. of Chrysarobin with 20 cc. of distilled water, and filter: the filtrate is neutral to litmus paper.

Ash: not more than 0.25 per cent.

Preserve in well-closed containers, protected from light.

U. S. P. Preparation—Unguentum Chrysarobini.

Uses—Chrysarobin has been largely used in certain skin diseases, notably psoriasis. It has fallen into disuse mainly on account of the almost indelible stain produced upon the skin and clothing when it is employed. Internally, chrysarobin is cathartic, in the dose of one-half grain (0.03 Gm.).

Unofficial Preparation

Neorobin, N. N. R.—A product obtained by the reduction of chrysarobin.

Neorobin is a yellow or yellowish-gray powder, slightly soluble in ether and methyl alcohol; more soluble in glacial acetic acid, chloroform, benzene and ethyl alcohol; readily soluble in acetone. Neorobin readily oxidizes when exposed to the air; also when in contact with fats.

Uses—The same as those of chrysarobin. It is claimed that neorobin is somewhat more active than chrysarobin and that it has the advantage over chrysarobin in that its staining qualities are markedly less.

It is applied in the form of ointments made with petrolatum, containing from 0.2 to 1 per cent (1 to 5 grains per ounce). Ointments must be freshly made, dispensed in collapsible tubes and used within two weeks from the time of preparation.

Manufactured by the H. K. Mulford Company, Philadelphia.

CAMBOGIA. U. S. Gamboge
[Cambog.—Pipe Gamboge]

Gamboge is the gum resin obtained from *Garcinia Hanburyi* Hooker filius (Fam. *Guttiferæ*).

Gamboge contains not more than 1 per cent of foreign organic matter, and yields not more than 1 per cent of acid-insoluble ash, and not less than 65 per cent of alcohol-soluble extractive.

Description—Cylindrical pieces, frequently hollow at the center, from 2 to 5 cm. in diameter, up to 20 cm. in length, longitudinally striate, grayish orange-brown; fracture brittle, conchoidal, presenting a smooth, rather dull, orange-red surface; odorless; taste acrid.

For further description see the U. S. P. X.

Assay—Proceed as directed under alcohol-soluble extractive, page 1523.

U. S. P. Preparation—Pilulæ Hydrargyri Chloridi Mitis Compositæ.

Gamboge contains about 75 per cent of resin called *gambogic acid*, which is dissolved by alkaline solutions, producing a red color; 20 per cent of gum is present, and this enables gamboge to be emulsified like the other gum resins.

Uses—It is a powerful hydragogue cathartic, and is generally used in combination with other substances, which modify its action. Dose, one-half to three grains (0.03 to 0.2 Gm.).

JALAPA. U. S. Jalap
[Jalap.]

Jalap is the dried tuberous root of *Exogonium Jalapa* (Nuttal et Coxe) Baillon (Fam. *Convolvulaceæ*).

Jalap yields not less than 7 per cent of the total resins of Jalap.

Description—Fusiform, irregularly ovoid or pyriform, the larger roots often incised or cut into pieces; from 4 to 15 cm. in length and from 1 to 10 cm. in diameter; externally dark brown, longitudinally wrinkled or furrowed and with numerous lenticels; hard, compact, not fibrous, internally light grayish-brown to dark brown, with a distinct brown cambium line; odors light but distinctive and smoky; taste somewhat sweet and acrid.

For further description see the U. S. P. X.

Assay—Place 10 Gm. of Jalap in fine powder in a dry flask, add 50 cc. of alcohol and stopper the flask with a perforated cork holding a reflux condenser. (An open glass tube of not less than 0.6 M. in length will suffice.) Place the flask on a water bath, and digest for three hours with occasional shaking. Then transfer to a small percolator, allow to drain, and percolate with alcohol, until the percolate measures 100 cc. Allow to cool to room temperature, and add alcohol to make exactly 100 cc. Mix well.

Transfer 20 cc. of this tincture, accurately measured, representing 2 Gm. of Jalap, to a separator, and add 10 cc. of chloroform and 20 cc. of a saturated solution of potassium citrate (20 Gm. of potassium citrate dissolved in 12 cc. of distilled water). Shake well during two minutes, then set aside for not less than ten hours or overnight. Draw off and discard the lower aqueous liquid, and filter the alcohol-chloroform solution through a small filter, wetted with alcohol-chloroform, into a tared flask or beaker. Rinse the separator with a mixture of 10 cc. of alcohol and 5 cc. of chloroform, and pass the rinsing through the filter. Mix the chloroformic liquids, evaporate on a water bath, dry at 100° C., and weigh.

U. S. P. Preparations—Pilulæ Hydrargyri Chloridi Mitis Compositæ; Pulvis Jalapæ Compositus; Resina Jalapæ.

N. F. Preparations—Fluidextractum Jalapæ, Pilulæ Catharticæ Vegetabiles (from Resin); Pulvis Hydrargyri Chloridi Mitis et Jalapæ; Syrupus Sennæ Aromaticus; Tinctura Jalapæ; Tinctura Jalapæ Compositæ.

Jalap contains from 8 to 16 per cent of resin, the greater part of which is *convolvulin*, or *jalapurgin*, $C_{62}H_{100}O_{32}$, a glucoside insoluble in ether; there are also present gum, sugar, starch, etc. The value of jalap depends exclusively upon the amount of convolvulin present, and the U. S. Pharmacopœia gives an assay for the resins.

Uses—Jalap is an esteemed cathartic, and is generally used in combination with substances having similar properties. Dose, ten to twenty grains (0.6 to 1.3 Gm.).

IPOMŒA. U. S. Ipomea

[Ipom.—Orizaba Jalap Root, Mexican Scammony Root]

Ipomea is the dried root of *Ipomœa orizabensis* Ledenois (Fam. *Convolvulaceæ*).

Ipomea yields not less than 15 per cent of the total resins of Ipomea, and not more than 3 per cent of acid-insoluble ash.

Because of the difficulty of obtaining *Levant Scammony*, Ipomea, which is claimed to possess practically identical therapeutic activity, has replaced the true scammony in all official preparations. The chemical constituents of Ipomea are not identical with those of Scammony but are related. It is also official in the British Pharmacopœia (1914).

Description—Nearly flat transverse slices, from 2 to 12 cm. in diameter, and from 1 to 5.5 cm. in thickness; externally light to dark brown, very deeply wrinkled; fracture tough, fibrous; cut surface light brown, showing concentric rings from which coarse fibers protrude; odor distinct, somewhat aromatic; taste slightly sweet, becoming somewhat acrid.

For further description see the U. S. P. X.

Assay—Proceed as directed under *Jalapa*, page 1085.

U. S. P. Preparations—Extractum Colocynthidis Compositum (from Resin); Resina Ipomœæ.

N. F. Preparations—Pilulæ Aloes, Hydrargyri et Scammonii Compositum (from Resin); Pilulæ Colocynthidis Compositæ (from Resin); Pilulæ Colocynthidis et Hyoscyami (from Resin); Tinctura Jalapæ Composita (from Resin).

True scammony root, of the U. S. P. IX, was the dried root of *Convolvulus Scammonia* Linné (Fam. *Convolvulaceæ*). It was required to yield not less than 8 per cent of the total resins of scammony root.

Scammony root contains from 8 to 9 per cent of a resin having cathartic properties, called *scammonin*, or *orizabin*, $C_{34}H_{56}O_{16}$; this is identical with the jalapin obtained from *Ipomœa orizabensis* (see *U. S. Dispensatory*, 20th edition).

Uses—Ipomea and scammony are hydragogue cathartics; they are usually combined with other purgatives. Dose, four to ten grains (0.25 to 0.6 Gm.).

PODOPHYLLUM. U. S. Podophyllum

[Podoph.—Mandrake, May Apple Rhizome]

Podophyllum consists of the dried rhizome and roots of *Podophyllum peltatum* Linné (Fam. *Berberidaceæ*).

Podophyllum yields not less than 3 per cent of the resin of podophyllum.

Description—Rhizome nearly cylindrical, jointed, compressed on the upper and lower surfaces, sometimes branched; in pieces usually less than 20 cm. in length, the internodes from 2 to 9 mm. in diameter, some of the nodes thickened; dark brown; longitudinally wrinkled or nearly smooth, with irregular somewhat V-shaped scars of scale leaves; some of the nodes annulate, the upper portion with large, circular, depressed stem-scars and with buds or stem-bases; on the lower portion numerous root-scars or roots from 2 to 7 cm. in length and about 2 mm. in thickness; fracture short; internally the cork light brown, the wood portion a circle of small yellowish vascular bundles and the pith large and white; odor slight; taste disagreeably bitter and acrid.

For further description see the U. S. P. X.

Assay—Proceed as directed under *Jalapa*, page 1085, using 10 Gm. of Podophyllum in fine powder.

U. S. P. Preparation—Resina Podophylli.

N. F. Preparations—Pilulæ Aloes et Podophylli Compositæ (from Resin); Pilulæ Aloes, Hydrargyri et Podophylli (from Resin); Pilulæ Aloini Compositæ (from Resin); Pilulæ Catharticæ Vegetabiles (from Resin).

Podophyllum contains *picropodophyllin*, *podophyllotoxin*, and *podophyllinic acid*. The resinous substances extracted from the powdered rhizome with alcohol contain the purgative principles.

Uses—It is cholagogue and cathartic, in doses of eight to twenty grains (0.5 to 1.3 Gm.).

COLOCYNTHIS. U. S. Colocynth

[Colocyn.—Colocynth Pulp, Bitter Apple, Colocynth Apple]

Colocynth is the dried pulp of the unripe but fully-grown fruit of *Citrullus Colocynthis* (Linné) Schrader (Fam. *Cucurbitaceæ*).

Colocynth contains not more than 5 per cent of seed and not more than 2 per cent of epicarp, and yields not more than 2 per cent of extractive with purified petroleum benzin, and not more than 6 per cent of acid-insoluble ash.

Description—In light, spongy, easily-broken pieces; yellowish-white or light brown with occasional small patches of darker epicarp; odor slight; taste intensely bitter. Fruits before removal of seed, nearly globular, from 4 to 10 cm. in diameter, with three large lenticular cavities between the three carpels, hence easily separable longitudinally into three parts. Seeds ovoid, compressed, light yellow to brown.

For further description see the U. S. P. X.

Assay—Proceed as directed under non-volatile ether-soluble extractive, page 1523, using purified petroleum benzin as the solvent.

U. S. P. Preparations—Extractum Colocynthidis; Extractum Colocynthidis Compositum (from Extract); Pilulæ Hydrargyri Chloridi Mitis Compositæ (from Compound Extract).

N. F. Preparations—Pilulæ Antiperiodicæ (from Compound Extract); Pilulæ Catharticæ Vegetabiles (from Compound Extract).

Colocynth contains *colocynthin*, $C_{56}H_{84}O_{23}$, *colocynthitin*, gum, resin, etc. Colocynthin is a very bitter glucoside, splitting under the action of diluted acids into colocynthein and grape sugar. The seeds should be rejected as far as possible, not more than 5 per cent being permitted by the U. S. P.

Uses—Colocynth is a hydragogue cathartic. Dose, one to five grains (0.06 to 0.3 Gm.).

ELATERINUM. U. S. Elaterin

[Elaterin.]

A substance obtained from the juice of the fruit of *Ecballium Elaterium* (Linné) A. Richard (Fam. *Cucurbitaceæ*).

Preparation—It may be made by evaporating an alcoholic tincture of elaterium to the consistence of thin oil, and throwing the residue while yet warm into a weak boiling solution of potassium hydroxide. The potassium hydroxide holds the green resin in solution, and the elaterin crystallizes as the liquor cools. It may also be made by exhausting elaterium with chloroform, and adding ether to the solution, which precipitates the elaterin.

Elaterium—When the fruit of the squirting cucumber is sliced and placed upon a sieve, a perfectly limpid and colorless juice flows out, which soon becomes turbid, and in the course of a few hours begins to deposit a sediment. This, when collected and carefully dried, is very light, and pulverulent, of a yellowish-white color, slightly tinged with green, and is called elaterium. The yield is small—only six grains from forty cucumbers—but the elaterium is very active, one-eighth of a grain purging violently. Commercial elaterium is not usually made in this way, but by expression or other processes, whereby the yield is increased; this elaterium is, of course, weaker.

Description and Physical Properties—Minute, white scales or prismatic crystals.

It is odorless, and is stable in the air.

Elaterin is insoluble in water. One Gm. is soluble in 325 cc. of alcohol, 310 cc. of benzene, 15.5 cc. of chloroform, and 450 cc. of ether, at 25° C. One Gm. is soluble in 100 cc. of boiling alcohol.

Tests for Identity—Its alcoholic solution is neutral to moistened litmus paper.

To a solution of about 0.01 Gm. of Elaterin in 5 Gm. of melted phenol, add a few drops of sulphuric acid: the mixture becomes crimson, the color rapidly changing to scarlet.

Tests for Purity—The ash from 0.1 Gm. is negligible.

Shake 0.1 Gm. of Elaterin with a mixture of 9 cc. of distilled water and 1 cc. of diluted hydrochloric acid, and filter; separate portions of the filtrate yield no turbidity with 0.5 cc. of mercuric potassium iodide T.S. or iodine T.S. (*alkaloids*).

Uses—Elaterin is the purgative principle of elaterium. The dose is one-twentieth to one-twelfth of a grain (0.003 to 0.005 Gm.).

BRYONIA. N. F. Bryonia

[Bryony]

Bryonia is the dried root of *Bryonia alba* Linné or of *Bryonia dioica* Jacquin (Fam. *Cucurbitaceæ*).

Bryonia contains not more than 5 per cent of foreign organic matter.

It contains starch, gum, sugar and *bryoresin* and the glucosides *bryonin* and *bryonidin*. *Bryogenin*, a resin, is also present.

Description—Usually in circular or elliptical slices, obtained by cutting the root more or less transversely, from 1.5 to 10 cm. in breadth and from 3 to 15 mm. in thickness; the edges light gray or yellowish, rough and striate, the cut surface white or faintly yellow, showing a thin cortex and a wood with numerous projecting, collateral fibro-vascular bundles arranged in concentric zones; fracture short and mealy, whitish internally. Odor faint, but distinct and characteristic; taste bitter and nauseous.

For further description see the N. F. V.

N. F. Preparation—Tinctura Bryoniæ.

Uses—It is used as a hydragogue purgative. Dose, fifteen grains (1 Gm.).

CASSIA FISTULA. N. F. Cassia Fistula

[**Cass. Fist.**—Purging Cassia]

Cassia Fistula is the dried fruit of *Cathartocarpus Fistula* (Linné) Persoon (Fam. *Leguminosæ*).

Cassia Fistula contains not more than 2 per cent of foreign organic matter.

It yields about 25 per cent of pulp, which contains pectin, sugar, albuminous principles, salts, etc.

Description—Cylindrical, from 25 to 50 cm. in length, about 20 mm. in diameter, chestnut-brown in color, on one side a longitudinal groove and on the other a smooth line or slight ridge, indicating the sutures; indehiscent, the cavity divided transversely into numerous compartments, each containing a reddish-brown, glossy, flattish-ovoid seed embedded in a blackish-brown sweet pulp. Odor resembling that of prunes.

For further description see the N. F. V.

N. F. Preparation—Confectio Sennæ.

Uses—The pulp is laxative. Dose, one drachm (4 Gm.).

EUONYMUS. N. F. Euonymus

[**Euonym.**—Wahoo Bark]

Euonymus is the dried bark of the root of *Euonymus atropurpureus* Jacquin (Fam. *Celastraceæ*).

Euonymus contains not more than 5 per cent of adhering wood or more than 2 per cent of other foreign organic matter, and yields not more than 4 per cent of acid-insoluble ash.

This bark contains resins, a bitter principle called *euonymin*, *euonic acid*, starch, asparagin, and pectin.

Description—Usually in transversely curved pieces, occasionally in single quills from 2 to 7 cm. in length; bark from 1 to 2.5 mm. in thickness; very light in weight; outer surface grayish or light brown, somewhat wrinkled, occasionally transversely fissured from the lenticels and with scale patches of soft cork; inner surface grayish-white, longitudinally striate and somewhat porous; fracture short with silky, projecting elastic fibers. Odor distinct; taste bitter and acrid.

For further description see the N. F. V.

N. F. Preparations—Extractum Euonymi; Fluidextractum Euonymi.

Uses—Euonymus is used as a cholagogue cathartic. It is stated to exert a digitalis-like action on the circulation. The dose is five to thirty grains (0.3 to 2 Gm.).

Caution—It has been stated that the absorption of Euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient.

FICUS. N.F. Fig

Ficus is the clean, sound, partially dried fruit of *Ficus Carica* Linné (Fam. *Moraceæ*). It contains mucilaginous constituents, sugar, fat, gum, etc.

Description—Usually compressed, of irregular rounded shapes, from 2.5 to 5 cm. in diameter, fleshy, light brown to yellow, frequently with an efflorescence of sugar; summit with a small, scaly orifice; base with a scar or short stalk; internally hollow, with numerous small, brownish-yellow, glossy, and hard akenes. Odor distinctive, fruity; taste sweet, pleasant.
For further description see the N. F. V.

N.F. Preparations—Confectio Sennæ; Syrupus Ficorum Compositus.

Uses—Figs are nutritious, demulcent, and laxative.

FRANGULA. N.F. Frangula
(U. S. P. IX)
[Frang.—Buckthorn Bark]

Frangula is the dried bark of *Rhamnus Frangula* Linné (Fam. *Rhamnaceæ*).
Frangula contains not more than 2 per cent of foreign organic matter.

Description—In quills varying in length, frequently flattened or crushed; from 0.5 to 1 mm. in thickness; outer surface grayish-brown or purplish-black, with numerous prominent, lighter colored, transverse lenticels and occasional patches of foliaceous lichens bearing small, blackish, apothecia; inner surface smooth, dark brown with occasional purplish blotches, longitudinally striate, becoming red when moistened with solutions of the alkalies; fracture short, slightly fibrous in the inner layer. Odor distinctive; taste slightly bitter.
For further description see the N. F. V.

N.F. Preparations—Elixir Catharticum Compositum (from Fluidextract); Fluidextractum Frangulæ; Syrupus Sennæ Compositus (from Fluidextract).

This bark contains *frangulin*, $C_{20}H_{20}O_9$, emodin, *frangulic acid*, isoemodin, tannin, resin, and other constituents.

Uses—When frangula is fresh, it is emetic; when old, it is a useful cathartic. The dose is fifteen grains (1 Gm.).

JUGLANS. N.F. Juglans
[Butternut Bark]

Juglans is the dried inner bark of the root of *Juglans cinerea* Linné (Fam. *Juglandaceæ*).
Juglans contains not more than 2 per cent of adhering wood or other foreign organic matter.
It contains a crystalline resin, *juglandic acid*, gum, sugar, etc.

Description—In quills, curved strips, or in chips, from 3 to 10 mm. in thickness; of a deep brown color on both surfaces and throughout, except for the faint, intersecting, whitish, radial and tangential lines shown in the transverse section; outer surface smooth, somewhat warty inner surface smooth and striate, bearing fragments of thin stringy fiber; fracture short, rather weak, somewhat fibrous. Odor faintly aromatic; taste bitter, astringent, somewhat acrid.
For further description see the N. F. V.

N.F. Preparations—Elixir Cascaræ Sagradæ Compositum (from Fluidextract); Fluidextractum Juglandis.

Uses—A mild cathartic and hepatic stimulant. Dose, one drachm (4 Gm.).

LEPTANDRA. N.F. Leptandra
[Leptand.—Culver's Root]

Leptandra consists of the dried rhizome and root of *Veronica virginica* Linné (Fam. *Scrophulariaceæ*).
Leptandra contains not more than 5 per cent of its stem bases or other foreign organic matter and yields not more than 6 per cent of acid-insoluble ash.

Leptandra contains a crystalline principle, *leptandrin*, resin, tannin, saponin, gum, mannite, etc. Crystalline leptandrin is bitter, and soluble in water, alcohol, and ether.

Description—Rhizome usually of horizontal growth, nearly cylindrical, somewhat branched, branches readily separable from the main rhizome, from 4 to 10 cm. in length and from 4 to 13 mm. in diameter; externally grayish-brown to dark reddish-brown, annulate from circular scars of bud-scales, upper surface with short stem remnants, occasionally with buds and numerous circular stem-scars; from the under and lateral portions arise numerous coarse roots; fracture very tough and woody; internally, bark rather thin, dark brown and resinous, wood about the same thickness as the bark, light brown and porous, pith large, more or less hollow, the color being similar to that of the bark. Roots from 1 to 10 cm. in length and from 1 to 2 mm. in diameter; externally dark brown to purplish-brown, smooth and faintly longitudinally wrinkled; fracture short; internally with a thick brownish-black bark and small light brown central cylinder. Nearly odorless; taste very bitter and acrid.

For further description see the N. F. V.

N. F. Preparations—Extractum Leptandræ; Fluidextractum Leptandræ; Pilulæ Catharticæ Vegetabiles (from Extract).

Uses—Leptandra is a cholagogue cathartic, in doses of fifteen to forty grains (1 to 2.6 Gm.).

PRUNUM. N. F. Prune

Prune is the partly dried, ripe fruit of *Prunus domestica* Linné (Fam. *Rosaceæ*).

Prune should contain 30 to 35 per cent of its natural moisture when used for pharmaceutical purposes. This fruit contains sugar, malic acid, pectin, salts, etc.

Description—Oblong, ellipsoidal, more or less compressed, from 3 to 4 cm. in length; externally brownish-black, shriveled; the sarcocarp sweet and acidulous; putamen hard, smooth or irregularly ridged; seed, shaped like that of the almond but smaller; bitter almond-like taste.

N. F. Preparation—Confectio Sennæ.

Uses—The pulp is laxative.

RHAMNUS CATHARTICA. N. F. Rhamnus Cathartica

[Rhamn. Cathart.—Buckthorn Berries, Baccæ Spinæ Cervinæ]

Rhamnus Cathartica is the dried, ripe fruit of *Rhamnus cathartica* Linné (Fam. *Rhamnaceæ*).

Rhamnus Cathartica contains not more than 5 per cent of unripe fruit or other foreign organic matter.

It contains *rhamnonigrin*, a glucoside, also *emodin*, coloring matter, fat, pectin, gum, etc.

Description—Flattened, globoid, or ovoid, from 4 to 8 mm. in diameter; externally purplish-black, wrinkled from shrinking of the mesocarp in drying; three- to four-celled, each cell containing a brown, triangular-convex, seed-like nutlet; in the fully dried, ripe fruit the pedicel is usually lacking. Odor faint, unpleasant; taste at first sweetish, then nauseating and bitter; it colors the saliva purplish-red.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Rhamni Catharticæ; Syrupus Rhamni Catharticæ (from Fluidextract).

Uses—A cathartic, used chiefly in veterinary practice. Dose, fifteen grains (1 Gm.).

Unofficial Drugs containing Cathartic Principles

Colutea Bladder Senna	The leaves of *Colutea arborescens* Linné (Fam. *Leguminosæ*). It is slightly purgative and is used chiefly in domestic treatment, in infusions (℥i to Oi)
Kamala (Rottlera).	The glands and hairs from the capsules of *Mallotus philippinensis* (Lamarck) Mueller Arg. (Fam. *Euphorbiaceæ*). It contains *rottlerin*, resins, coloring matter, etc. Used as a tænifuge and purgative in doses of one to three drachms (4 to 12 Gm.) suspended in mucilage or syrup

Drugs Containing Astringent Principles, and their Preparations

The term tannin is used specifically to denote gallotannic acid or digallic acid (Acidum Tannicum U. S. P.), or as a generic term for a large group of substances possessing certain properties in common.

The distinguishing properties of the tannins have been summarized as follows:

They are colloidal and possess astringent properties.

They precipitate gelatin from solution and form insoluble compounds with certain animal tissues, which is taken advantage of in conversion of hide into leather.

They all give dark blue or dark green reactions in solution with ferric salts, a fact which is utilized in the manufacture of ink.

They are precipitated from solution by many metallic salts as lead acetate, etc.

They are precipitated from solution by solution of potassium dichromate or by solution of chromic acid.

They precipitate alkaloids from solution and also precipitate organic colors of basic character.

In alkaline solutions they readily absorb oxygen and become darker in color.

With solution of potassium ferricyanide and ammonia, a deep red color is produced.

Tannins are widely distributed in the vegetable kingdom. The constitution of many of the tannins is very complex. A simple relationship exists between tannic acid from nutgalls (gallotannic acid, the U. S. P. tannic acid) and gallic acid, the former being considered an anhydride of the latter as shown by the following reaction:

$$\underset{\text{gallotannic acid}}{C_{14}H_{10}O_9} = \underset{\text{gallic acid}}{2C_7H_6O_5} + \underset{\text{water}}{H_2O}$$

This change takes place spontaneously in aqueous solutions of tannic acid and is an explanation of the necessity of using glycerin as a solvent for stable solutions of tannic acid, and the use of hydroalcoholic menstrua, usually with glycerin also, in the extraction of the astringent drugs.

Many of the tannins are of a glucosidal nature and exist in the plant in combination with carbohydrates.

Many varieties of tannin are named from the plant in which they occur as gallotannic acid, catechutannic acid, kinotannic acid, quercitannic acid, caffetannic acid, etc.

Among the decomposition products of the tannins are the substances known as *phlobaphenes* which are characterized by a red color and their insolubility in water.

In the tannin-containing drugs these compounds frequently occur as distinctive coloring matters along with the tannins and are named according to their origins as kola red, oak bark red, etc.

GALLA. U. S. Nutgall

[Gall.—Aleppo Galls, Smyrna Galls]

Nutgall is the gall from the young twigs of *Quercus infectoria* Olivier and other allied species of *Quercus* (Fam. *Fagaceæ*).

Description—Nearly globular, from 0.8 to 2.5 cm. in diameter, heavy, mostly sinking in water; externally dark olive-green to dark grayish, tuberculated on upper portion; basal portion smooth and contracted into a short stalk; fracture short, horny; internally grayish to dark brown, with a central slightly radiate portion; occasionally with a central cavity connected by a narrow, radial canal to the external surface; odor slight; taste strongly and persistently astringent.

For further description see the U. S. P. X.

U. S. P. Preparation—Unguentum Gallæ.

N. F. Preparation—Tinctura Gallæ.

Nutgall contains about 50 per cent of tannin, 2 per cent of gallic acid, sugar, gum, resin, and starch.

Uses—It is used an an external astringent. Dose, eight to fifteen grains (0.5 to 1 Gm.).

ACIDUM TANNICUM. U. S. Tannic Acid

[Acid. Tann.—Gallotannic Acid, Tannin]

A tannin usually obtained from nutgall.

Preparation—In manufacturing tannic acid on the large scale, the finely powdered galls are stirred with sufficient water at 50° to 60° C. to form a concentrated aqueous extract, and after filtration the clear liquid is agitated with one-fourth of its volume of ether until an emulsion results. After standing for several days, the upper ethereal liquid, which contains fatty and waxy impurities, is removed, and the lower layer, which contains all the tannin, is run into a still and the ether is recovered. After cooling the syrupy liquid is spread out on sheets of tin, and heated by means of a steam coil, when the product rapidly puffs up and dries.

Thus prepared the commercial tannin contains some quantity of gallic acid, plant wax, glucose and other impurities; to remove these, the material may be washed with ether, or the aqueous liquid fractionally precipitated with common salt, the precipitate dissolved in ethyl acetate, and the tannin recovered by evaporation under reduced pressure.

Description and Physical Properties—An amorphous powder, glistening scales, or spongy masses, varying in color from yellowish-white to light brown. It is odorless, or has a faint, characteristic odor and a strongly astringent taste.

Tannic Acid is very soluble in water, acetone, and alcohol. It is freely soluble in diluted alcohol and slightly soluble in dehydrated alcohol. It is almost insoluble in benzene, chloroform, ether, and in petroleum benzin. One Gm. of Tannic Acid dissolves in about 1 cc. of warm glycerin.

Tests for Identity—The addition of a small quantity of ferric chloride T.S. to an aqueous solution of the Acid produces a bluish-black color or precipitate.

An aqueous solution of Tannic Acid produces precipitates in solutions of most of the alkaloids and glucosides and also in solutions of gelatin, albumin, and starch.

Tests for Purity—Tannic Acid loses not more than 12 per cent of its weight when dried to constant weight at 100° C.

Ash: not more than 0.5 per cent.

Dissolve 2 Gm. of Tannic Acid in 10 cc. of hot distilled water: the solution is not more than slightly turbid and no turbidity is produced upon diluting separate 5 cc. portions of the cooled and filtered solution with 10 cc. of alcohol (*gum or dextrin*), or with 10 cc. of distilled water (*resinous substances*).

Preserve in well-closed containers, in a cool place, protected from light.

U. S. P. Preparations—Glyceritum Acidi Tannici; Trochisci Acidi Tannici; Unguentum Acidi Tannici.

N. F. Preparations—Collodium Stypticum; Syrupus Iodotannicus.

Uses—Tannic acid is powerfully astringent, in doses of three to ten grains (0.2 to 0.6 Gm.). It is frequently employed as an astringent in the form of ointment, chiefly for hemorrhoids. Its solution in glycerin is a valuable liquid form of administration.

Official Tannic Acid Derivatives

The following abstract is taken from the N. N. R: "The pharmacologic actions of tannic acid are due to its property of precipitating protein. Internally, tannic acid has been used in diarrhea; but if tannic acid is given as such, it is rapidly dissolved in the stomach, and may then produce excessive gastric irritation, nausea and even vomiting. The desire to avoid these effects has prompted the introduction of relatively insoluble compounds of tannin, which would act but little, if at all, in the stomach and whose action would extend farther down the intestines. This was sought to be accom-

plished by utilizing the differences in reaction (hydrogen ion concentration) at the various levels of the alimentary tract. It was therefore aimed to make the compounds insoluble in diluted acids, and soluble in diluted alkalies. This object, however, has not been entirely attained and is probably not really desirable in view of the frequent slightly acid reaction of the intestinal contents. It is probably more important that the compound should be but slowly soluble in any reaction that occurs in the alimentary tract."

Four such types have been marketed: (1) organic esters of tannic acid, represented by the official acetyltannic acid; (2) coagulated tannin proteinate, represented by the official albumin tannate; (3) tannin caseinate (protan); (4) a heterogeneous group of other compounds, such as bismuth salts, exemplified by the official bismuth subgallate. The third type is not recognized by the U. S. P. or the N. N. R.

Importance of Differences in Solubility—All the compounds are somewhat soluble in water; but not sufficiently soluble to affect their therapeutic usefulness. From the latter standpoint, the solubility in acid gastric juice and the solubility in sodium bicarbonate solution, representing the maximum alkalinity of the intestines, are most important. The speed or slowness of solution is at least as important as the absolute solubility.

Of the three types, the acetyltannic acid is the least soluble in gastric juice; albumin tannate is fairly soluble, but the solution occurs rather slowly; protan is the most soluble, and the solution occurs more rapidly.

Uses—The sparingly soluble tannic acid preparations are used in diarrheal affections, particularly those of children. They should be employed, not as the principal curative agent, but as an occasional adjunct to the proper physical and dietetic remedies when the discharges are unduly profuse.

As has been explained, acetyltannic acid and albumin tannate act at all levels of the intestine.

For a method for testing tannic acid compounds for solubility in the intestines see the N. N. R.

ACIDUM ACETYLTANNICUM. U. S. Acetyltannic Acid

[**Acid. Acetyltan.**—Diacetyltannic Acid, Tannyl Acetate, Acetannin]

Tannigen is the name under which the product is sold by the Bayer Company.

Acetyltannic Acid is a product obtained by the acetylization of tannic acid.

Description and Physical Properties—A yellowish-white, or a grayish-white powder which darkens on exposure to light. It is odorless or has a slight acetous odor.

Acetyltannic Acid is only slightly soluble in water and in alcohol, but is soluble in ethyl acetate. It is soluble with gradual decomposition in aqueous solutions of alkali hydroxides and carbonates. It is also soluble in aqueous solutions of sodium borate and of sodium phosphate.

Tests for Identity—Warm 0.2 Gm. of Acetyltannic Acid with 2 cc. of alcohol and 2 cc. of sulphuric acid: the odor of ethyl acetate is noticeable. A solution of Acetyltannic Acid in sodium phosphate T.S. (1 in 100) after standing for several hours precipitates albumin solution, but this property is destroyed by the presence of an excess of alkali. When dissolved in an aqueous solution of sodium borate (1 in 25), it does not precipitate albumin.

Tests for Purity—Ash: not more than 0.3 per cent.

Dry about 1 Gm. of Acetyltannic Acid, accurately weighed, for three hours at 100° C.: the loss does not exceed 3 per cent.

Shake 1 Gm. of Acetyltannic Acid with 50 cc. of distilled water during five minutes and filter; a 25 cc. portion of the filtrate requires for neutralization not more than 1.2 cc. of tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator (*free acid*). To the remainder of the filtrate add 2 drops of ferric chloride T.S.: a green but not a blue color is produced (*free tannic acid*).

Digest 1 Gm. of Acetyltannic Acid with a solution of 2 Gm. of sodium bicarbonate in 200 cc. of distilled water for three hours at about 40° C., filter through a counterbalanced filter or a Gooch crucible, wash the insoluble residue with 4 portions of distilled water, 10 cc. each, and dry to constant weight at 110° C. The weight of the residue does not exceed 0.15 Gm.

Digest 1 Gm. of Acetyltannic Acid with 200 cc. of distilled water for two hours, shaking at frequent intervals. Filter, through a dry filter into a dry flask, rejecting the first 20 cc. of the filtrate, evaporate 100 cc. of the subsequent filtrate to dryness on a water bath, and dry the residue for three hours at 100° C. The weight of the residue does not exceed 0.03 Gm. (*soluble substances*).

Preserve in well-closed containers, protected from light.

Uses—See the general article above.

Average dose—10 grains (0.6 gm.).

ALBUMINI TANNAS. U. S. Albumin Tannate

[**Album. Tan.**—ALBUTANNIN]

A compound of albumin and tannic acid.

Description and Physical Properties—A yellowish-white, odorless powder.

It is almost insoluble in water, alcohol, chloroform, and ether. It is decomposed by aqueous solutions of alkali hydroxides and carbonates.

Tests for Purity—Ash: not more than 0.3 per cent.

Dry about 1 Gm. of Albumin Tannate for three hours at 100° C.: the loss does not exceed 6 per cent.

Shake 1 Gm. of Albumin Tannate with 50 cc. of distilled water for five minutes and filter: a 25 cc. portion of the filtrate requires for neutralization not more than 1 cc. of tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator (*free acid*).

Digest 1 Gm. of Albumin Tannate with 200 cc. of distilled water for two hours, shaking at frequent intervals. Filter through a filter, which has not been previously moistened, into a dry flask, rejecting the first 20 cc. of the filtrate. Evaporate 100 cc. of the subsequent filtrate to dryness on a water bath and dry the residue for three hours at 100° C.: the weight of the residue does not exceed 0.06 Gm. (*soluble substances*).

Place 1.5 Gm. of Albumin Tannate in a 500 cc. glass-stoppered flask. Dissolve 2.5 Gm. of sodium bicarbonate in 250 cc. of distilled water, warm the solution to 40° C., and gradually add it with agitation to the Albumin Tannate. Then add a filtered aqueous solution of 0.25 Gm. of pancreatin in 5 cc. of distilled water. Place the flask in a suitable bath, maintain at 40° C. for two hours, inverting the flask every ten minutes. Allow to remain in the bath for one-half hour longer without inverting. Filter through a counterbalanced filter, wash the undissolved residue with four 10 cc. portions of cold distilled water, and dry to constant weight at 110° C.: the weight of the residue does not exceed 0.45 Gm.

Place 1.5 Gm. of Albumin Tannate in a 500 cc. glass-stoppered flask. Mix 20 cc. of normal hydrochloric acid with 230 cc. of distilled water, warm the mixture to a temperature of 40° C., and add it gradually with agitation to the Albumin Tannate. Then add a filtered aqueous solution of 0.25 Gm. of pepsin in 5 cc. of distilled water. Place the flask in a suitable bath and maintain at 40° C. for two hours, inverting the flask during the digestion every ten minutes. Allow the flask to remain in the bath for another half hour without inverting. Filter through a counterbalanced filter, wash the undissolved residue with four 10 cc. portions of cold distilled water, and dry at 110° C. to constant weight: the weight of the residue is not less than 0.6 Gm.

Preserve protected from light.

Uses—See the general article above.

Average dose—30 grains (2 Gm.).

Unofficial Tannic Acid Derivatives

Protan. N. N. R.—Tannin Nucleo-Proteid-Mulford—A chemical combination of casein with tannic acid containing about 50 per cent tannic acid.

Protan is made by adding a solution of tannic acid to an alkaline solution of casein, collecting and drying the precipitate.

It is a light brown powder, tasteless, and free from astringent action on the mouth and stomach; insoluble in water or dilute acids, and does not coagulate albumin or precipitate pepsin or peptones.

Actions and Uses—Protan is said to be useful as an intestinal astringent in all forms of diarrhea.

Dose—For infants and children, from 0.3 to 0.6 Gm. (5 to 10 grains) every hour; in acute catarrhal diarrhea (cholera morbus), from 1 to 2 Gm. (15 to 30 grains) every one or two hours; in chronic diarrhea from 1.3 to 2 Gm. (20 to 30 grains) every hour or two hours.

Manufactured by The H. K. Mulford Company, Philadelphia.

ACIDUM GALLICUM. (U. S. P. IX) Gallic Acid

An organic acid [$C_7H_6O_5.H_2O$ or $C_6H_2(OH)_3.COOH1:3:4:5.H_2O = 188.10$].

Preparation—Gallic Acid may be prepared as follows: Take of nutgall, in fine powder, 36 oz., purified animal charcoal, distilled water, each, a sufficient quantity. Mix the nutgall with sufficient distilled water to form a thin paste, and expose the mixture to the air, in a shallow glass or porcelain vessel, in a warm place for a month, occasionally stirring it with a glass rod, and adding from time to time sufficient distilled water to preserve the semifluid consistence. Then submit the paste to expression, and reject the expressed liquor, boil the residue in 8 pints of distilled water for a few minutes, and filter while hot, through purified animal charcoal. Set the liquid aside that crystals may form, and dry them on bibulous paper. If the crystals are

not sufficiently free from color, they may be purified by dissolving them in boiling distilled water, filtering through a fresh portion of purified animal charcoal, and again crystallizing. Gallic acid may be prepared synthetically. It is closely related to tannic acid, and both are usually found together in the same plants.

Description—White, or pale fawn-colored, silky, interlaced needles, or in triclinic prisms.

Odor, Taste, and Reaction—Odorless and having an astringent and slightly acidulous taste permanent in the air. A saturated aqueous solution of Gallic Acid is acid to litmus.

Solubility—One Gm. of Gallic Acid dissolves in 87 cc. of water, 4.6 cc. of alcohol, 10 cc. of glycerin, and in about 100 cc. of ether at 25° C.; also in about 3 cc. of boiling water almost insoluble in chloroform.

Tests for Identity—Add 6 drops of sodium hydroxide T.S. to 5 cc. of a cold, saturated aqueous solution of the Acid: a deep green color gradually develops, which is changed to reddish or brownish-red by acids.

Gallic Acid neither colors nor precipitates solutions of pure ferrous salts, but it forms a bluish-black precipitate with ferric salts.

Impurities and Tests for Impurities—When dried to constant weight at 100° C. the Acid loses not more than 12 per cent of its weight.

Incinerate about 1 Gm. of Gallic acid; not more than 0.1 per cent of ash remains.

Tannic Acid—A cold saturated aqueous solution of Gallic Acid yields no precipitate with gelatin T.S. or starch T.S.

Uses—Gallic acid is used as an internal astringent. Dose, five to fifteen grains (0.3 to 1 Gm.).

KRAMERIA. U.S. Krameria

[Rhatany]

Krameria is the dried root of *Krameria triandra* Ruiz et Pavon, known in commerce as Peruvian Rhatany, or of *Krameria argentea* Martius, known in commerce as Para or Brazilian Rhatany (Fam. *Leguminosæ*).

The chief constituent is *krameria-tannic acid*, also starch, sugar, gum, and *krameric acid*.

Description—*Peruvian Rhatany*—Crown knotty, several- to many-headed, with numerous branching roots; the latter up to 50 cm. in length and usually less than 1 cm. in thickness, cylindrical or somewhat tapering, flexuous or wavy, externally light reddish-brown or brownish-red, more or less marked with darker scaly cork especially in the upper portion, somewhat longitudinally wrinkled but devoid of transverse fissures; fracture of bark slightly fibrous, of wood tough and splintery; the bark pinkish-brown internally and less than one-third of the radius, the wood yellowish or pinkish-white and finely radiate; inodorous; bark astringent, wood nearly tasteless.

Para Rhatany—Roots usually separate from the crown, less flexuous, tapering, tough and internally darker in color than those of Peruvian Rhatany, and usually not exceeding 12 mm. in thickness; externally purplish-brown or chocolate-brown and marked with numerous fissures; the bark about two-fifths or more of the radius.

For further description see the U. S. P. X.

U. S. P. Preparation—Tinctura Krameriæ.

N. F. Preparations—Extractum Krameriæ; Fluidextractum Krameriæ; Fluidglyceratum Krameriæ; Syrupus Krameriæ.

Uses—It is an astringent, used in diarrhea and leucorrhea. Dose, fifteen grains (1 Gm.).

PYROGALLOL. U.S. Pyrogallol

[**Pyrogall.**—Pyrogallic Acid]

Trihydroxybenzene [$C_6H_3(OH)_3$ 1:2:3 = 126.08].

When gallic acid is sublimed, it is converted by the heat into pyrogallol and carbon dioxide.

$$\underset{\text{gallic acid}}{C_7H_6O_5} = \underset{\text{pyrogallol}}{C_6H_6O_3} + \underset{\substack{\text{carbon}\\\text{dioxide}}}{CO_2}$$

Description and Physical Properties—Light, white, or nearly white, odorless leaflets or fine needles. It acquires a grayish tint on exposure to air and light.

One Gm. of pyrogallol is soluble in 1.7 cc. of water, in 1.3 cc. of alcohol, and in 1.6 cc. of ether at 25° C. It is very soluble in boiling water and in boiling alcohol.

Tests for Identity—Pyrogallol melts between 130° and 133° C.

An aqueous solution of Pyrogallol on exposure to air acquires a brown color and an acid reaction due to oxidation by the air. Absorption of oxygen and change of color take place very rapidly after the solution is rendered alkaline with an alkali hydroxide.

An aqueous solution of Pyrogallol (1 in 10) reduces solutions of the salts of silver, gold, and mercury even in the cold.

When freshly prepared, 1 cc. of an aqueous solution of Pyrogallol (1 in 20) is colored brownish-red by a few drops of ferric chloride T. S. Freshly prepared ferrous sulphate T. S. produces a blue color in an aqueous solution of Pyrogallol (1 in 20).

Tests for Purity—Ash: not more than 0.1 per cent.

A freshly prepared solution of Pyrogallol (1 in 20) in recently boiled, distilled water is colorless or at most slightly yellow, and is neutral or only slightly acid to litmus paper.

Preserve in well-closed containers, protected from light.

Uses—Pyrogallol is used in the form of ointment in the treatment of psoriasis, although its use is not without danger. It is also employed in photography as a developer.

GAMBIR. U. S. Gambir

[Pale Catechu]

Gambir is the dried aqueous extract prepared from the leaves and twigs of *Ourouparia Gambir* (Hunter) Baillon (Fam. *Rubiaceæ*).

Gambir yields not less than 70 per cent of water-soluble extractive and not less than 60 per cent of alcohol-soluble extractive.

Description—Masses approximately cubical or rectangular, from 20 to 30 mm. in diameter; externally pale grayish-brown to reddish-brown, more or less dull and porous; friable, internally of a light brown or dark gray color; inodorous; taste bitterish and very astringent.

For further description see the U. S. P. X.

Assay—Proceed as directed under water-soluble extractive, page 1523, and alcohol-soluble extractive, page 1523.

U. S. P. Preparation—Tinctura Gambir Composita.

N. F. Preparation—Tinctura Opii et Gambir Composita (from Compound Tincture).

Gambir was introduced into the U. S. P. to replace the formerly official catechu, because the former can be obtained in commerce much more uniform in quality. It contains *catechutannic acid*, a peculiar form of tannin, which is insoluble in ether and turns greenish-black with ferric salts. *Catechin* and *catechol* are also present. Owing to the decomposition of the tannic acid, the liquid preparations often gelatinize.

Uses—It is used as an astringent, especially in diarrhea. Dose, fifteen grains (1 Gm.).

KINO. U. S. Kino

Kino is the dried juice obtained from the trunk of *Pterocarpus Marsupium* Roxburgh (Fam. *Leguminosæ*).

Kino yields not less than 45 per cent of alcohol-soluble extractive and not less than 80 per cent of water-soluble extractive.

Description—Small, brittle, angular fragments, usually less than 10 mm. in diameter, varying in color from dark reddish-brown to reddish-black; inodorous; taste very astringent; upon mastication coloring the saliva pink.

For further description see the U. S. P. X.

Assay—Proceed as directed under alcohol-soluble extractive (page 1523), and water-soluble extractive (page 1523).

U. S. P. Preparation—Tinctura Kino.

Kino contains *kinotannic acid*, pyrocatechin, kino-red, kinoin, gum, etc. Owing to the decomposition of the kinotannic acid, the liquid preparations, if not protected, frequently gelatinize. Tincture of kino is heated to destroy an enzyme which it is said induces gelatinization by aiding in the decomposition of the kinotannic acid.

Uses—Kino is used as an astringent, especially for diarrhea. Dose, five to twenty grains (0.3 to 1.3 Gm.).

ROSA U. S. Rose

[Rosa Gallica U. S. P. IX, Red Rose]

Rose is the dried petals of *Rosa gallica* Linné (Fam. *Rosaceæ*), collected just before the expansion of the flowers.

Description—Petals either separate or imbricated in small cones, broadly ovate, summit rounded and deeply notched, margin entire and somewhat recurved, base obtuse; externally of a purplish-red color, except the light brown claw; texture velvety; when dry brittle; odor agreeable, taste astringent and slightly bitter.

U. S. P. Preparations—Fluidextractum Rosæ; Mel Rosæ (from Fluidextract).
N. F. Preparations—Confectio Rosæ; Infusum Rosæ Compositum; Pilulæ Aloes et Mastiches; Syrupus Rosæ (from Fluidextract).

Red rose contains *quercitrin* and *quercitannic acid*. The pale red coloring matter is made bright red by the addition of sulphuric acid.

Uses—It is slightly astringent, but is used chiefly for its odor and color. The infusion of red rose is a useful vehicle for many substances. (See page 361.)

UVA URSI. U. S. Uva Ursi

[Bearberry]

Uva Ursi is the dried leaf of *Arctostaphylos Uva-ursi* (Linné) Sprengel (Fam. *Ericaceæ*).

Uva Ursi contains not more than 5 per cent of its stems or other foreign organic matter.

Description—Usually unbroken, obovate, oblong or spatulate, from 12 to 30 mm. in length, from 5 to 13 mm. in breadth; apex obtuse or rounded; margin entire slightly revolute; base cuneate, tapering into a short, stout petiole, upper surface dark green, glabrous and shiny, finely reticulate; under surface yellowish-green and slightly pubescent, especially on the midrib; coriaceous; fracture short; odor slightly aromatic, tea-like; taste astringent and somewhat bitter.
For further description see the U. S. P. X.

U. S. P. Preparation—Fluidextractum Uvæ Ursi.
N. F. Preparations—Elixir Buchu Compositum (from Compound Fluidextract of Buchu); Fluidextractum Buchu Compositum.

Uva Ursi contains about 6 per cent of tannic acid, with gallic acid, *ursón*, *arbutin*, *ericolin*, gum, resin, coloring matter, etc.

Uses—It is used as a urinary antiseptic. Dose, thirty grains (2 Gm.).

CASTANEA. N. F. Castanea

[Castan.—Chestnut Leaves]

Castanea consists of the dried leaf of *Castanea dentata* (Marshall) Vorkhausen (Fam. *Fagaceæ*).

Castanea contains not more than 5 per cent of its stems or other foreign organic matter.
It contains about 9 per cent of tannic acid and also mucilage.

Description—Petioles stout, about 12 mm. in length; blades entire or slightly broken and usually folded or matted together; about 15 to 25 cm. in length and about 5 cm. in breadth, oblong-lanceolate, apex attenuate, acute at the base, coarsely and sharply serrate with ascending attenuate teeth, nearly smooth, coriaceous in texture; the upper surface dark green, the lower light green; distinctly pinnately veined, the veins of the first order diverging at an angle of about 60 degrees, each terminating in one of the teeth. Odor slight; taste astringent.
For further description see the N. F. V.

N. F. Preparation—Fluidextractum Castaneæ.

Uses—It is used in whooping-cough. Dose, one drachm (4 Gm.).

CHIMAPHILA. N. F. Chimaphila

[**Chimaph.**—Pipsissewa]

Chimaphila consists of the dried leaf of *Chimaphila umbellata* (Linné) Barton (Fam. *Ericaceæ*).

Chimaphila contains not more than 5 per cent of its stems and other foreign organic matter.

Chimaphila contains about 5 per cent of tannic acid, with *chimaphilin, ericolin, arbutin, urson, sugar, gum,* etc.

Description—Oblanceolate, from 2.5 to 7 cm. in length and from 8 to 20 mm. in breadth, the upper portion coarsely and sharply serrate, acute or somewhat obtuse, the lower wedge-shaped and nearly entire; coriaceous, smooth and uniformly dark green on the upper surface, paler beneath, the veins prominent. Odor slight; taste astringent and bitter.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Chimaphilæ; Fluidextractum Stillingiæ Compositum.

Uses—It is used in inflammations of the genito-urinary organs, in doses of thirty grains (2 Gm.).

GERANIUM. N. F. Geranium

[**Geran.**—Cranesbill]

Geranium is the dried rhizome of *Geranium maculatum* Linné (Fam. *Geraniaceæ*).

Geranium yields not more than 2 per cent of foreign organic matter.

Geranium contains about 15 per cent of tannic acid, with brownish-red coloring matter, starch, sugar, pectin, etc.

Description—Rhizome cylindraceous, somewhat branched, bent, flattened and strongly tuberculated, from 2.5 to 10 cm. in length and from 3 to 15 mm. in diameter; surface marked with root scars and remnants of slender roots, longitudinally wrinkled; externally dark purple-brown; internally light purple-brown; fracture short, non-fibrous, the section shows a thin bark, a distinct cambium, irregular in outline, large central pith, wood indistinct, the fibro-vascular bundles few and at unequal distances. Odorless; taste strongly astringent.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Geranii.

Uses—It is used as an astringent. Dose, fifteen grains (1 Gm.).

HÆMATOXYLON. N. F. Hæmatoxylon

See Chapter LX on Coloring Substances.

HAMAMELIS FOLIA. N. F. Hamamelis Leaves

[**Hamamel. Fol.**—Witch Hazel Leaves]

Hamamelis leaves consists of the dried leaf of *Hamamelis virginiana* Linné (Fam. *Hamamelidaceæ*).

Hamamelis leaves contains not more than 5 per cent of stems or more than 2 per cent of other foreign organic matter.

It contains small amounts of tannin and bitter principles and a volatile oil.

Description—Petioles from 1 to 1.5 cm. in length; laminæ when entire, broadly elliptical or rhomboid-ovate, usually inequilateral, mostly from 8 to 12 cm. in length; summits usually acute, sometimes rounded or acuminate; bases slightly heart-shaped and oblique; margins sinuate or sinuate-dentate; upper surfaces pale or brownish-green, occasionally dark brown with a few stiff, straight hairs; lower surfaces lighter in color, somewhat hairy, midrib and veins prominent. Odor slight; taste astringent, slightly aromatic and bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Hamamelidis Foliorum.

Uses—It has been extensively used as an astringent and hemostatic, but its virtues have been greatly exaggerated. Dose, thirty grains (2 Gm.).

QUERCUS. N. F. Quercus

[Querc.—White Oak Bark]

Quercus is the dried inner bark of the trunk and branches of *Quercus alba* Linné (Fam. *Fagaceæ*).

Quercus contains not more than 2 per cent of its outer bark or wood or other foreign organic matter.

The most important constituents are *quercitannic acid* and *oak-red*, also pectin, resin, wax, fat, the sugar *quercit*, etc.

Description—In nearly flat pieces, from 2 to 10 mm. in thickness; externally light brown, becoming darker with age, rough-fibrous; fracture uneven, coarsely fibrous. Odor distinct; taste strongly astringent; not tingeing the saliva yellow when chewed.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Quercus.

Uses—It is an astringent, used in leucorrhea, and in hemorrhoids. Dose, fifteen grains (1 Gm.).

RUBUS. N. F. Rubus

[Blackberry Bark]

Rubus consists of the dried bark of the rhizome and roots of the section *Eubatus* Focke, of the genus *Rubus* Linné (Fam. *Rosaceæ*).

Rubus contains not more than 10 per cent of adhering wood and not more than 2 per cent of other foreign organic matter.

Rubus owes its astringent properties to tannic acid. There are also present gum, coloring matter, etc.

Description—In elongated, tough, flexible quills or bands, from 3 to 6 mm. in diameter, the bark from 1 to 2 mm. in thickness; outer surface deep red-brown or dark gray-brown, occasionally blackish-brown, somewhat scaly; inner surface yellow or pale brown, strongly and coarsely long straight-striate; fracture tough-fibrous; readily splitting. Inodorous; taste strongly astringent and bitter.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Rubi; Syrupus Rubi (from Fluidextract).

Uses—Rubus is used as an astringent chiefly in diarrhea. The dose is fifteen grains (1 Gm.).

RUMEX. N. F. Rumex

[Yellow Dock, Curled Dock]

Rumex is the dried root of *Rumex crispus* Linné, or of *Rumex obtusifolius* Linné (Fam. *Polygonaceæ*).

Rumex contains not more than 5 per cent of its stem bases or other foreign organic matter.

It contains *rumicin*, said to be isomeric with chrysophanic acid. *Nepodin* and *lapodin* are also present.

Description—Usually split longitudinally or cut into transverse pieces about 2 cm. in length. The entire root, nearly simple, slightly tapering, with few if any rootlets, somewhat twisted, up to 30 cm. in length and 7 cm. in diameter, externally reddish-brown or grayish from adhering soil, finely annulate above, deeply wrinkled longitudinally, marked with small indented root scars which are often transversely elongated and with occasional stem scars or remains of stems, the latter being hollow and finely striated; leaf buds few, obconical; fracture short and dusty, somewhat fibrous.

The transverse section exhibits a yellowish or brownish cortex and a whitish or yellowish wood which is finely radiate in the outer portion. When examined under the microscope, it exhibits a thick cortex with several layers of cork, beneath which is an interrupted row of stone cells; a distinct cambium; and vascular bundles with few fibers.

Tests for Identity and Purity—The powder, when examined under the microscope, shows calcium oxalate crystals in rosette aggregates from 0.025 mm. to 0.06 mm. in diameter; numerous starch grains ellipsoidal or narrowly elongated, sometimes truncate, up to 0.025 mm. in length, stone cells from 0.04 mm. to 0.2 mm. in diameter with walls somewhat lamellated, from 0.008 mm. to 0.025 mm. in thickness and with few simple pores; sclerenchymatous fibers, few, thin-walled with simple pores; tracheæ up to 0.1 mm. in width with scalariform or reticulate thickenings of the wall; cork cells light brown.

Rumex yields not more than 10 per cent of ash.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Rumicis.

Uses—It is used as an astringent, applied locally in scrofulous disorders. Dose, one drachm (4 Gm.).

Unofficial Astringent Substances

Agrimonia Agrimony	From *A. Eupatoria*, grown in North America. It contains tannin and bitter principle
Areca Nut Semen Arecæ (Betel Nut)	Vermifuge. Dose, one to two drachms (4 to 8 Gm.)
Bistorta Bistort	The rhizome of *Polygonum B.*, grown in Canada and the United States. It contains about 20 per cent of tannin, etc.
Catechu Catechu	From *Uncaria Gambir*, grown in the East India Islands. It contains catechin, catechutannin, etc. (see Gambir, p. 1096)
Comptonia Sweet Fern	The leaves of *C. asplenifolia*, found in North America. It contains volatile oil, tannin, etc.
Diospyros Persimmon	The bark of *D. virginiana*, grown in the United States. It contains tannin and malic acid
Epigæa Trailing Arbutus	From *E. repens*, found in North America. It contains tannin, and the principles common to the *Ericaceæ*
Epilobium Willow Herb	From *E. angustifolium*, found in the Northern Hemisphere. It contains tannin, mucilage, etc.
Epiphegus Beech-drop	From *E. virginiana*, a parasitic plant found in North America. It contains tannin, bitter principle, etc.
Eugallol (Pyrogallol-mono-acetate)	A brownish-yellow, syrupy liquid, soluble in water. Used like pyrogallol in skin diseases. Applied externally
Gallanol (Gallic Acid Anilide, Gallinol, Gallanilide), $C_6H_5NH.CO.C_6H_2(OH)_3$	Prepared by boiling tannic acid with aniline. In grayish scales or powder, having a bitter taste, soluble in water, alcohol, and ether; very astringent. Used in skin diseases, in 3 to 20 per cent ointments, and as a dusting powder when mixed with talc
Hepatica Liverwort	The leaves of *H. triloba*, found in North America. It contains tannin, mucilage, etc.
Heuchera Alum root	The root of *H. americana*, found in the United States. It contains about 20 per cent of tannin
Hieraceum Hawkweed	From different species of *Hieraceum*, found in North America. It contains tannin
Hippocastanum Horsechestnut Bark	The bark of *Æsculus Hippocastanum*, grown in North America. It contains tannin and various other principles
Ilex Paraguayensis Maté, Paraguay Tea	The leaves of *I. paraguayensis*, grown in Brazil. It contains tannin and 10 to 15 per cent of caffeine, etc.
Monesia Monesia	From *Chrysophyllum glycyphlæum*, found in Brazil. A vegetable extract alterative and astringent. Dose, from two to ten grains (0.125 to 0.6 Gm.) every hour or two
Myrobalanus Myrobalans	From different species of *Terminalia*, grown in Southern Asia. It contains about 45 per cent of gallotannic acid
Nymphæa Water Lily	The rhizome of *N. odorata*, found in the United States. It contains tannin and mucilage
Potentilla Cinquefoil	From *P. canadensis*, found in North America. It contains tannin
Pulmonaria Lungwort	From *P. officinalis*, grown in Europe. It contains tannin
Quercus Tinctoria Black Oak Bark	From *Q. coccinea*, var. *tinctoria*, grown in the United States. It contains tannin, etc.
Rhus Aromatica Sweet Sumach	From *R. aromatica*. It contains tannin, coloring matter, gum resin, etc.
Rosa Centifolia Pale Rose	The petals of *Rosa centifolia* Linné (Fam. *Rosaceæ*). It contains tannin, volatile oil, sugar, etc. Used as a flavor
Saligallol (Pyrogallol Disalicylate)	A resinous solid, sold in the form of a 33 per cent solution in acetone. Used in skin diseases, and as a vehicle for other dermic preparations. It is applied externally in the form of a 2 to 15 per cent solution
Spiræa Hardhack	From *S. tomentosa*, found in North America. It contains tannin and bitter principle
Statice Marsh Rosemary	The root of *S. Limonium*, grown in Europe. It contains tannin and volatile oil
Tannoform (Methylene-ditannin, Tannin-formaldehyde) $CH_2(C_{14}H_9O_9)_2$	Obtained by adding formaldehyde to an aqueous solution of tannic acid and precipitating with hydrochloric acid. A reddish-brown powder insoluble in water. Used as a dusting powder, as a drying antiseptic, and in intestinal disorders. Dose, four to eight grains (0.25 to 0.5 Gm.)
Tormentilla Tormentil	From *T. erecta*, grown in Europe. It contains about 20 per cent of tannin

CHAPTER LXXIII

ALKALOIDS

SERTÜRNER'S paper, in 1817, "Morphia, a New Salt-forming Substance, and Meconic Acid, as the Chief Constituents of Opium", opened a new era of discovery in organic plant chemistry. His description of the first alkaloid separated was immediately followed by the isolation of narcotine by Robiquet and strychnine by Pelletier and Caventou. This class of principles was at first called vegetable alkalies, which was later changed to alkaloids, meaning alkali-like.

Alkaloids as the active principles of many plants were isolated and announced in rapid succession by various investigators until today they number hundreds, a few being obtained from Cryptogams (flowerless plants), but mainly from the Phanerogams (flowering plants), most of those isolated being from dicotyledons.

They are undoubtedly the most important organic compounds with which the pharmacist has to deal, and the most active, and potent substances he dispenses. His interest in them is two-fold—first for their medicinal value and, secondly, because of the intimate association of early pharmacists in their isolation and identification.

Alkaloids are obtained from the animal as well as from the vegetable kingdom. The term *leucomaines* is generally applied to those from living animal tissues and *ptomaines* to the product of decomposition in dead animal tissues. When found in plants, they occur in nearly all of the organs, and several theories, each of which has supporting facts, have been advanced as to the mode of formation. A more detailed discussion of these can be had by consulting one of the more extensive treatises on alkaloids, such as those referred to later.

Chemically they are all closely related to some simpler compound such as pyridine or quinoline, yet classification is difficult, as they often contain conflicting nuclei. The classification adopted below is based upon their main nucleus.

Pyridine—Piperine, coniine, pilocarpine, and nicotine.

Tropine—Atropine and the other solanaceous alkaloids. also cocaine and the coca alkaloids.

Quinoline—Quinine and other cinchona alkaloids, also strychnine and brucine.

Iso-quinoline—Papaverine, narcotine, hydrastine, berberine, and narceine.

Phenanthrene—Morphine, codeine, and thebaine.

Purine—Caffeine, theobromine, and theophylline.[1]

Gloxaline—Pilocarpine.

Unclassified—Physostigmine, aconitine, pelletierine, colchicine, and emetine.

Their distinctive chemical and physical features are as follows:

1. They are all nitrogenous and in addition contain carbon, hydrogen, and generally oxygen.

[1] Caffeine, theobromine and theophylline are grouped under alkaloids as they are similar in many respects and are still classed as such by many authorities. They however lack certain properties that most alkaloids possess, this is recognized by the Pharmacopœia in describing them as "feebly basic substances". A strict classification would place them under the derivatives of uric acid.

2. Most of the non-volatile alkaloids are solid; the volatile ones are mainly liquid and some contain no oxygen.

3. Alkaloids unite with acids to form additive salts. They are alkaline in reaction and are freed from their acid combinations by the addition of alkalies.

4. Most of them are physiologically active, some being extremely poisonous. In the majority of instances they are the medicinally important substances of the plants from which they are derived.

5. They are mainly crystallizable, though a few are liquid while some are amorphous.

6. They are generally colorless though berberine is yellow and sanguinarine, itself colorless, yields red salts.

7. They are either insoluble or sparingly soluble in water (a few exceptions, as colchicine) but soluble in alcohol, chloroform, benzene, some in ether, and a few in petroleum benzin. Their salts behave conversely in the matter of solubility.

8. Nearly all alkaloids exhibit definite optical activity, only a few being inactive. Some alkaloids, when salified, exhibit an optical activity directly opposite that shown in the free state.

9. They are precipitated by one or more of the following reagents; with some they form definite chemical compounds which are used for their identification: mercuric-potassium iodide (Mayer's reagent); potassium-cadmium iodide (Marme's reagent); potassium-bismuth iodide (Dragendorff's reagent); phosphomolybdic acid (Sonnenschein's reagent); a solution of iodine with potassium iodide (Wagner's reagent); phosphotungstic acid (Scheibler's reagent); gold chloride; tannic acid; and picric acid.

The manufacture of alkaloids is so highly specialized that the firms engaged in their commercial production make it a specialty and have devoted years to perfecting the processes. The operations involved are based on the physical as well as the chemical properties of the alkaloids sought. In many instances their commercial production requires merely a large scale operation similar to the methods employed in proximate assaying.

Purification is usually accomplished by the crystallization of the alkaloidal salts. A few alkaloids are made synthetically, as homatropine and codeine, and there are also numerous synthetic drugs of an alkaloidal character which do not occur naturally in any plants.

To identify separated alkaloids which have been properly purified, the melting point of the free alkaloid and of one of its salts may be obtained, also some other factors, as optical rotation, crystalline form, etc., Most alkaloids show characteristic specific rotation and the microscopic examination of the crystals obtained from the use of alkaloidal solutions of known concentration using suitable precipitants has given exceptionally good results.[1]

Color reactions are also used in establishing identity, but they should not be relied on solely, since the effect noted is often produced by impurities.

The alkaloids will be considered in this chapter in the order of their importance.

OPIUM. U.S. Opium

Opium is the air-dried, milky exudation obtained by incising the unripe capsules of *Papaver somniferum* Linné or its variety *album* De Candolle (Fam. *Papaveraceæ*).

[1]For further information the reader is referred to one of the following books:
Commercial Organic Analysis—Allen; Microchemical Test for Alkaloids—Stephenson; Plant Alkaloids—Henry; Chemistry and Analysis of Drugs and Medicines—Fuller; Vegetable Alkaloids—Pictet-Biddle; New and Non-Official Remedies.

Opium in its normal, moist condition yields not less than 9.5 per cent of anhydrous morphine.

Description—In more or less rounded, somewhat flattened masses, usually about 8 to 15 cm. in diameter; externally dark brown, covered with fragments of poppy leaves and at times with fruits of a species of rumex adhering from the packing; more or less plastic when fresh, becoming hard and brittle or tough on keeping; internally dark brown interspersed with lighter areas, somewhat lustrous; odor characteristic, narcotic; taste very bitter, characteristic.

Assay—Place 8 Gm. of Opium, which if fresh should be in very small pieces, and if dry in fine powder, into an Erlenmeyer flask having a capacity of about 250 cc., add 80 cc. of distilled water, stopper the flask, and agitate it every ten minutes (or continuously in a mechanical shaker) during three hours. Then pour the contents as evenly as possible upon a wetted filter having a diameter of not over 12 cm. and, when the liquid has drained off, wash the residue with distilled water, carefully dropped upon the edges of the filter and its contents until a filtrate of 120 cc. has been obtained. Carefully transfer the moist Opium to a mortar by means of a spatula and rub to a smooth paste, then rinse into the original flask with 50 cc. of distilled water, agitate it thoroughly, and return the whole to the filter. When the liquid has drained off, wash the residue with 75 cc. of distilled water. Evaporate the mixed filtrates and washings on a water bath to about 40 Gm.; transfer the extract to a 50 cc. graduated flask, and wash the evaporating dish with sufficient distilled water to make the entire volume measure exactly 50 cc. when cooled to room temperature. Place in a small mortar 4 Gm. of freshly slaked lime (page 1536), add about 10 cc. of the Opium extract and rub to a smooth paste, then add the remainder of the extract, and rinse the flask with exactly 10 cc. of distilled water, adding the rinsings to the mortar, and stir frequently during fifteen minutes, avoiding unnecessary loss by evaporation. Filter through a dry filter, about 10 cm. in diameter, and transfer exactly 30 cc. of the filtrate, representing 4 Gm. of Opium, to an Erlenmeyer flask of suitable capacity. To this add 2 cc. of alcohol and 15 cc. of ether, and after shaking the mixture add 1 Gm. of ammonium chloride, stopper the flask and shake it frequently during half an hour, then set it aside in a cool place for twelve hours or overnight. Remove the stopper, and brush any adhering crystals back into the flask. Decant the ethereal layer into a small funnel, the neck of which has been previously closed with a pledget of purified cotton. (A small filter paper may be used if preferred.) Rinse the flask and contents with 15 cc. of ether, and, when the ether has passed through, wash the funnel and cotton with a small quantity of ether, and then pour the aqueous liquid into the funnel without trying to remove the crystals. Wash the crystals in the flask and the contents of the funnel with distilled water previously saturated with morphine, until the washings are colorless. Then add a few drops of distilled water to replace the morphinated water. Incline the edge of the funnel over the mouth of the flask, and by means of a glass rod carefully transfer the cotton with adhering crystals to the flask. Insert the funnel into the neck of the flask and wash the funnel with 20 cc. of tenth-normal sulphuric acid, followed by 10 cc. of distilled water applied, drop by drop, around the edge of the funnel. Remove the funnel, replace the cork, warm gently, and agitate until the crystals are dissolved. Rinse the cork with distilled water and titrate the excess of acid with fiftieth-normal sodium hydroxide. Each cc. of tenth-normal sulphuric acid corresponds to 0.02853 Gm. of anhydrous morphine.

U. S. P. Preparations—Mistura Glycyrrhizæ Composita (from Camphorated Tincture); Opii Pulvis; Opium Deodoratum; Opium Granulatum; Pulvis Ipecacuanhæ et Opii; Tinctura Opii; Tinctura Opii Camphorata.

N. F. Preparations—Linimentum Opii Compositum; Lotio Plumbi et Opii; Mistura Carminativa; Mistura Magnesiæ, Asafœtidæ et Opii; Mistura Opii et Chloroformi Composita; Mistura Opii et Rhei Composita; Mistura Pectoralis, Stokes'; Pilulæ Opii et Camphoræ; Pilulæ Opii et Plumbi; Pulvis Cretæ et Opii Aromaticus; Syrupus Ipecacuanhæ et Opii (from Tincture); Tinctura Ipecacuanhæ et Opii (from Tincture of Deodorized Opium); Tinctura Opii Crocata.

History—The ancients recognized several kinds of opium. The superior kind was called *opion* and was the juice which exuded from the living poppy capsule, the inferior kind was called *meconion* and was in reality a solid extract made from the crushed leaves and capsules.

Dioscorides, in the second century, was the first writer to discuss opium and its uses at length. He gave the receipt for a preparation called *diacodion* which is the prototype of our official syrup of poppies. Paracelsus used opium extensively in the fifteenth century and referred to it as the "stone of immortality". Van Helmont, early in the seventeenth century used opium so freely that he was referred to as Doctor Opiatus. Sydenham a little later in the same century praised opium as the most valuable gift of God to mankind.

Uses—(See page 1107).

OPIUM PULVERATUM. U. S. Powdered Opium

[**Opium Pulv.**—Opii Pulvis U. S. P. IX, Opii Pulvis P. I.]

Opium dried at a temperature not exceeding 70° C. and reduced to a very fine powder.

Powdered Opium yields not less than 10 per cent and not more than 10.5 per cent of anhydrous morphine. Powdered Opium of a higher morphine percentage is to be reduced to the official standard by admixture with powdered opium of a lower percentage, or with some inert diluent.

Description—Light brown, consisting chiefly of yellowish-brown to brownish-red, more or less irregular and granular fragments.
Assay—Proceed as directed under *Opium*.
Preserve in well-closed containers.
For a further description see the U. S. P. X.

U. S. P. Preparations—Pulvis Ipecacuanhæ et Opii; Tinctura Opii Camphorata.
N. F. Preparations—Pilulæ Opii, Digitalis et Quininæ: Pilulæ Opii et Camphoræ; Pilulæ Opii et Plumbi; Pulvis Cretæ et Opii Aromaticus.

Uses—(See page 1107).

OPIUM GRANULATUM. U. S. Granulated Opium

[**Opium Gran.**]

Opium dried at a temperature not exceeding 70° C., and reduced to a coarse powder.

Granulated Opium yields not less than 10 per cent and not more than 10.5 per cent of anhydrous morphine. Granulated Opium of a higher morphine percentage may be brought within the required limits of strength by admixture with granulated opium of a lower percentage, or with some inert diluent.

Description and Physical Properties—When powdered, Granulated Opium corresponds to the description under *Opium Pulveratum*.
Assay—Proceed as directed under *Opium*.
Preserve in well-closed containers.

U. S. P. Preparation—Tinctura Opii.
N. F. Preparation—Tinctura Opii Crocata.

Uses—(See page 1107).

Opium Alkaloids, etc.—Opium as a drug has been cultivated for many centuries, but it was not until the investigations of Sertürner, published in 1817, that it was known that the drug contained certain definite principles now called *alkaloids*. Opium is produced almost entirely in European and Asiatic tropical and sub-tropical countries. That which is used in the manufacture of medicinal products comes mainly from Turkey and Smyrna. Persian and Indian opium is imported chiefly for the manufacture of the opium alkaloids. Opium owes its value to the narcotic alkaloids present in it. More than twenty-five alkaloids have been proved to exist in various kinds of opium, and several more have been announced, but their existence has not been confirmed. Two acids are found in opium combined with the alkaloids—*i.e.*, meconic and lactic acids; there are also present *meconin*, $C_{10}H_{10}O_4$, *meconoiosin*, $C_8H_{10}O_2$, both neutral principles, pectin, glucose, mucilage, caoutchouc, wax, and odorous, fatty, and coloring matters. *Meconic acid* is colored red by ferric salts, the color not being discharged by solution of mercuric chloride. A solution of potassium sulphocyanate is colored in a similar manner by ferric salts, but

this color is discharged by solution of mercuric chloride. The known alkaloids are as follows:

Morphine, $C_{17}H_{19}O_3N$
Codeine, $C_{18}H_{21}O_3N$
Neopine, $C_{18}H_{21}O_4N$ or $C_{18}H_{21}O_3N$
Pseudomorphine, $(C_{17}H_{18}O_3N)_2$
Thebaine, $C_{19}H_{21}O_3N$
Narcotine, $C_{22}H_{23}O_7N$
Gnoscopine (dl-narcotine), $C_{22}H_{23}O_7N$
Oxynarcotine, $C_{22}H_{23}O_8N$
Narceine, $C_{23}H_{27}O_8N$
Papaverine, $C_{20}H_{21}O_4N$
Laudanosine, $C_{21}H_{27}O_4N$
Laudanine, $C_{20}H_{25}O_4N$
Laudanidine, $C_{20}H_{25}O_4N$
Codamine, $C_{20}H_{25}O_4N$
Pseudopapaverine, $C_{21}H_{21}O_4N$
Papaveramine, $C_{21}H_{25}O_6N$
Xanthaline (Papaveraldine), $C_{20}H_{19}O_5N$
Protopapaverine, $C_{19}H_{19}O_4N$
Meconidine, $C_{21}H_{23}O_4N$
Lanthopine, $C_{23}H_{25}O_4N$
Protopine, $C_{20}H_{19}O_5N$
Cryptopine, $C_{21}H_{23}O_5N$
Tritopine, $(C_{21}H_{27}O_3N)_2O$
Rhœadine, $C_{21}H_{21}O_6N$
Hydrocotarnine, $C_{12}H_{15}O_3N$

Morphine, $C_{17}H_{19}O_3N.H_2O$, is the chief principle of opium and the first alkaloid discovered (see separate article, page 1107).

Codeine, $C_{18}H_{21}O_3N.H_2O$, is an important narcotic alkaloid obtained from opium (see page 1109).

Narcotine, $C_{22}H_{23}O_7N$. Derosne, in 1803, obtained from opium a substance, "opium salt", which was a mixture of narcotine and morphine. He erroneously supposed it to be the narcotic principle, and did not recognize its alkaloidal character. Narcotine was isolated by Robiquet in 1817. It is white, tasteless, and inodorous, and crystallizes in silky, flexible needles, usually larger than the crystals of morphine, $[a]_D$ $-198.0°$ in chloroform, $+50°$ in 1 per cent hydrochloric acid, melting point 176° C., insoluble in cold water, soluble in 400 parts of boiling water, in 100 parts of cold alcohol, and in 24 parts of boiling alcohol, which deposits it upon cooling, and in 166 parts of ether at 16° C., readily soluble in benzene, acetone, or ethyl acetate. When opium is extracted with water to obtain the morphine and codeine, the narcotine remains in the insoluble residue. It is present in opium from 1 to 9 per cent. It is colored red by a mixture of sulphuric and nitric acids. It is *not narcotic*, but is said to be antiperiodic.

Thebaine (Paramorphine). This alkaloid occurs in opium to the extent of 0.1 to 1 per cent and was obtained originally by Thiboumery, who named it *paramorphine*, $C_{19}H_{21}O_3N$. Crystallized from alcohol in white leaflets of an acrid and styptic rather than bitter taste, $[a]_D$ $-218.6°$ in alcohol, melting point about 193° C., scarcely soluble in water, very soluble in alcohol, chloroform and benzene, and sparingly soluble in ether when cold, and even more insoluble when heated. Alkalies precipitate it from its acid solutions, and, unless in very concentrated solution, do not dissolve it when added in excess. Unlike morphine, it is not reddened by nitric acid, nor does it become blue with solutions of ferric salts. It is colored blood-red by sulphuric acid which on warming turns orange-yellow and finally olive green. It is not narcotic, but in its effects on the system is closely analogous to strychnine, producing tetanic spasms in the dose of a grain (0.06 Gm.).

Papaverine, $C_{20}H_{21}O_4N$, was isolated by Merck in 1848. Crystallizable in needles, melting point 147° C., $[a]_D$ 0°., and volatilizable at 154.4° C. It is insoluble in water, very sparingly soluble in cold alcohol or ether, more soluble in these liquids when boiling hot, and deposited by them on cooling: soluble in benzene and chloroform. Dissolves in pure cold sulphuric acid to a colorless solution, becoming rose-red at 110° C, violet at 200° C, the color being discharged by water. It is narcotic.

Narceine, $C_{23}H_{29}O_9N.3H_2O$. Discovered by Pelletier in 1832. Crystallizes from alcohol in white, silky crystals, inodorous, of a bitter taste, $[a]_D$ 0°, melting

point 170° C., and volatilizable at 215.5° C. (420° F.), soluble in 1285 parts of cold and 220 of boiling water, slightly soluble in cold 80 per cent alcohol (1 in 945 at 13°), and insoluble in ether. It forms a bluish compound with a little iodine, the color of which is destroyed by heat and the alkalies. It is rendered blue by the action of mineral acids diluted so as not to decompose it; but, unlike morphine, it does not become blue by the action of ferric salts, or red by that of nitric acid. Narceine is narcotic, and may be given in doses of one-third to one-half of a grain (0.02 to 0.03 Gm.).

Hydrocotarnine, $C_{12}H_{15}O_5N$, is soluble in alcohol, acetone, chloroform, petroleum benzin, and ether. It melts at 55° C., and loses at a somewhat greater heat the half molecule of water with which it crystallizes. Sulphuric acid dissolves it, coloring it yellow in the cold, and crimson red if heated. Nitric acid colors it yellow; ferric chloride does not affect its color.

Pseudomorphine, $C_{34}H_{36}O_6N_2$, isolated by Pelletier in 1835, shows several reactions like morphine. It dissolves in concentrated nitric acid with an intense orange-red color, and in solution of ferric chloride with a blue color. It may be prepared by oxidation of morphine. Silky crystals insoluble in water or organic solvents but soluble in aqueous or alcoholic ammonia. It is tasteless and physiologically inactive.

Cryptopine, $C_{21}H_{23}O_5N$, produces a blue color with sulphuric acid; it is but slightly soluble in water or alcohol. It is narcotic.

Protopine, $C_{20}H_{19}O_5N$, is insoluble in water, soluble in alcohol and chloroform.

Laudanine, $C_{20}H_{25}O_4N$. Crystallizes from dilute alcohol in prisms; melting point 166° C.; $[a]_D$ 0°; soluble in chloroform, benzene or alcohol. Gives a deep red color with sulphuric acid and iron oxide. A strong tetanic poison.

Codamine, $C_{20}H_{25}O_4N$. Isomeric with laudanine. Crystallizes from ether in hexagonal prisms. Melting point 126° C. Moderately soluble in water and soluble in alcohol; colored green with nitric acid and ferric chloride.

Rhœadine, $C_{21}H_{21}O_6N$. Nearly insoluble in water, alcohol, ether, petroleum benzin, and chloroform; melting point 232° C. With sulphuric acid or hydrochloric acid it turns a purple color. It is non-toxic.

Meconidine, $C_{21}H_{23}O_4N$. Amorphous; easily soluble in alcohol, ether, benzene, and chloroform; melting point 58° C., colored olive-green by sulphuric acid, orange-red by nitric acid.

Laudanosine, $C_{21}H_{27}O_4N$. Produces rose color with sulphuric acid, violet when heated; soluble in ether.

Lanthopine, $C_{23}H_{25}O_4N$. Sparingly soluble in chloroform, melting point 200° C. With sulphuric acid a pale violet color is given which changes to brown on heating.

Gnoscopine (*dl*-narcotine), $C_{22}H_{23}O_7N$. This alkaloid presumably does not exist in opium but is produced from narcotine by racemization. Colorless needles, melting point 229° C.

Neopine, $C_{18}H_{21}O_4N$. An amorphous alkaloid soluble in water, alcohol, ether, chloroform or benzene. It gives color reactions similar to those of codeine.

Laudanidine, $C_{20}H_{25}O_4N$. Occurs with laudanine, of which it is supposed to be the lævo-form. Melting point 177° C, $[a]_D$ −87.8° in chloroform.

Pseudopapaverine, $C_{21}H_{21}O_4N$. Usually a constituent of commercial papaverine. Melting point 147° C.

Papaveramine, $C_{21}H_{25}O_6N$. Colorless prisms. Melting point 128° to 129° C.

Xanthaline (Papaveraldine), $C_{20}H_{19}O_5N$. Colorless scales; melting point 210° C.

Protopapaverine, $C_{19}H_{19}O_4N$.

Tritopine, $(C_{21}H_{27}O_6N)_2O$. This alkaloid is said to be physiologically inactive. It has a melting point of 182° C. It is easily soluble in chloroform but insoluble in ether.

Oxynarcotine, $C_{22}H_{23}O_8N$. Nearly insoluble in water, alcohol, chloroform, and benzene, but soluble in alkaline solutions.

Uses—Opium is narcotic, sedative, and antispasmodic. The dose of powdered opium is one grain (0.065 Gm.). The official preparations are listed on page 1103.

The use and sale of opium, its alkaloids and derivatives and other narcotics and habit-forming drugs, are subject to rigid Federal regulation under the *Harrison Act*, and by many states which have enacted similar regulations. These are explained in a special Chapter on Laws. See Part VII.

MORPHINA

Morphine, $C_{17}H_{19}O_3N$. Morphine in the form of the pure alkaloid is no longer official, as the salts are more soluble and better adapted for use in medicine. It was the first alkaloid to be discovered.

In the seventeenth and eighteenth centuries many attempts were made to separate from opium the principle to which its activity was due. Preparations claimed to represent these active principles, but which were really extracts, were employed in medicine under the name of *Magisterium Opii*. Bucholz was the first to endeavor to obtain a crystalline product from opium. About 1800 a number of learned apothecaries of the time were devoting their attention to the separation of the suspected active principle. In 1806, Friedrich William Adam Sertürner, an apothecary of Eimbeck, Germany, announced the separation of a basic crystalline substance which existed in opium in combination with a special acid. He later published, in 1817, the results of further investigation in which he named the substance *morphium* and described it as a *vegetable alkali*. Sertürner was later awarded a prize of 2000 francs for his discovery, by the French Institute of Science. Liebig, in 1831, assigned to it the formula $C_{34}H_{36}O_6N$, which was later modified by Laurent to $C_{17}H_{19}O_3N$.

Preparation—Morphine may be prepared by the former official process, as follows:

Opium, sliced, 12 oz. troy; ammonia water, 6 fl. oz.; animal charcoal, in fine powder, alcohol, distilled water, each, a sufficient quantity. Macerate the opium with 4 pints of distilled water for twenty-four hours, and, having worked it with the hand, again macerate for twenty-four hours and strain. In like manner, maccrate the residue twice successively with the same quantity of distilled water and strain. Mix the infusions, evaporate to 6 pints, and filter; then add 5 pints of alcohol, and afterwards 3 fl. oz. of the ammonia water, previously mixed with 8 fl. oz. of alcohol. After twenty-four hours, pour in the remainder of the ammonia water, mixed, as before, with 8 fl. oz. of alcohol; and set the liquid aside for twenty-four hours that crystals may form. To purify these, boil them with 2 pints of alcohol until they are dissolved, filter the solution, while hot, through animal charcoal, and set it aside to crystallize.

In this process the infusions containing the morphine, in combination with meconic and lactic acids, are treated with alcohol and ammonia water. The former retains the coloring matter, caoutchouc, resins, etc., in solution, while the ammonia combines with the natural acids, the morphine being precipitated as an insoluble precipitate.

Description—In colorless or white, shining, rhombic prisms, in fine needles, or as a crystalline powder; permanent in the air. Odorless. A saturated aqueous solution of Morphine is alkaline to litmus.

Solubility—One Gm. of Morphine dissolves in 3340 cc. of water, 210 cc. of alcohol, 1220 cc. of chloroform, 6250 cc. of ether, and 100 cc. of lime water, at 25° C., also in 1075 cc. of boiling water and 98 cc. of boiling alcohol; insoluble in benzene.

Tests for Identity and Purity—(See Morphine Sulphate).

MORPHINÆ HYDROCHLORIDUM. U.S. Morphine Hydrochloride

[Morph. Hydrochl.—Morphine Chloride]

The hydrochloride $[C_{17}H_{19}O_3N.HCl.3H_2O = 375.76]$ of an alkaloid obtained from opium.

Preparation—This salt may be prepared by mixing morphine with distilled water and carefully adding hydrochloric acid, drop by drop, until the

morphine is neutralized and dissolved. Evaporate the solution on a water bath, to the consistence of a syrup and set it aside until it crystallizes. Lastly dry the mass at a gentle heat.

Description and Physical Properties—White, silky, glistening needles, or cubical masses, or a white, crystalline powder. It is odorless, and is stable in the air.

One Gm. of Morphine Hydrochloride is soluble in 17.5 cc. of water and in 52 cc. of alcohol, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water and in 46 cc. of alcohol at 60° C. It is soluble in glycerin, but insoluble in chloroform and in ether.

Tests for Identity—Silver nitrate T.S. added to an aqueous solution of the salt produces a white precipitate, insoluble in nitric acid.

Morphine Hydrochloride responds to the tests for identity for morphine under *Morphinæ Sulphas*.

Tests for Purity—Morphine Hydrochloride loses not more than 15 per cent when dried to constant weight at 100° C. (*water*).

Add 2 cc. of potassium carbonate T.S. to 5 cc. of an aqueous solution of the salt (1 in 30), and gently shake the mixture: a white precipitate is produced which does not become green on exposure to air, or color chloroform when shaken with it (*apomorphine*).

Morphine Hydrochloride also complies with the tests for purity under *Morphinæ Sulphas*.

Preserve in well-closed containers, protected from light.

Uses—Morphine hydrochloride is preferred to the sulphate in Great Britain as a narcotic and sedative. The dose is one-eighth to one-fourth of a grain (0.008 to 0.015 Gm.).

MORPHINÆ SULPHAS. U.S. Morphine Sulphate

[Morph. Sulph.]

The sulphate $[(C_{17}H_{19}O_3N)_2.H_2SO_4.5H_2O = 758.65]$ of an alkaloid obtained from opium.

Preparation—This useful salt may be made by the former official process, as follows:

Take of morphine, in fine powder, 1 oz. troy: distilled water, 8 fl. oz.; diluted sulphuric acid, a sufficient quantity. Mix the morphine with the distilled water, then carefully drop in diluted sulphuric acid, constantly stirring until the morphine is neutralized and dissolved. Evaporate the solution by means of a water bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper.

Description and Physical Properties—White, feathery, silky crystals, or cubical masses, or a white, crystalline powder. It is odorless, and is stable in the air.

One Gm. of Morphine Sulphate is soluble in 15.5 cc. of water and in 565 cc. of alcohol, at 25° C. One Gm. is soluble in 0.7 cc. of water at 80° C. and in 240 cc. of alcohol at 60° C. It is insoluble in chloroform and in ether.

Tests for Identity—Add a few drops of ammonia T.S. to 5 cc. of an aqueous solution of Morphine Sulphate (1 in 30), and gently shake the mixture: a white precipitate is formed, which dissolves upon the subsequent addition of a few cc. of sodium hydroxide T.S.

Sulphuric acid containing 0.005 Gm. of selenous acid in each cc. gives with Morphine Sulphate a blue color, changing to green and then to brown. (*Codeine* yields a green color, changing to blue and afterward to grass-green.) Sulphuric acid containing 0.005 Gm. of molybdic acid in each cc. gives a purple color, changing to blue. Sulphuric acid containing in each cc. one drop of formaldehyde T.S. yields an intensely purple color. With nitric acid Morphine Sulphate produces an orange-red color fading to yellow.

The addition of a few drops of freshly prepared ferric chloride T.S. to an aqueous solution of Morphine Sulphate (1 in 100) produces a blue color, which is destroyed by acids, alcohol, or by heating. Add potassium ferricyanide T.S., containing 1 drop of ferric chloride T.S. in each cc., to an aqueous solution of the salt (1 in 100): a deep blue color is produced at once (*difference from codeine*).

Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in hydrochloric acid.

Tests for Purity—A solution of 0.5 Gm. of the salt in 15 cc. of distilled water requires not more than 0.5 cc. of fiftieth-normal sodium hydroxide for neutralization, using one drop of methyl red T.S. as indicator.

Dried to constant weight at 130° C., Morphine Sulphate loses not more than 12 per cent (*water*).

The ash from 0.5 Gm. is negligible.

Warm 0.2 Gm. of Morphine Sulphate with 5 cc. of sodium hydroxide T.S.: the odor of ammonia is not noticeable (*ammonium salts*).

Add a few drops of ferric chloride T.S. to 5 cc. of an aqueous solution of the salt (1 in 30), previously mixed with 5 cc. of diluted hydrochloric acid: no red color is produced (*meconate*).

Dissolve 1 Gm. of Morphine Sulphate in 10 cc. of sodium hydroxide T.S. in a separator, and shake the solution with three successive portions of 15, 10, and 10 cc. of chloroform, passing the

chloroform solutions through a small filter previously moistened with chloroform. Shake the combined chloroform solutions with 5 cc. of distilled water, separate the chloroform, and evaporate it carefully to dryness on a water bath. Add to the residue thus obtained 10 cc. of fiftieth-normal sulphuric acid, heat gently until dissolved, cool, add two drops of methyl red T.S., and titrate the excess of acid with fiftieth-normal sodium hydroxide: not less than 7.5 cc. of the latter is required (*foreign alkaloids*).

Preserve in well-closed containers, protected from light.

N. F. Preparations—Mistura Chloroformi et Morphinæ Composita; Syrupus Pini Albæ Compositus cum Morphina.

Uses—Morphine sulphate is much more largely prescribed in the United States than any other salt of morphine. The dose is one-eighth to one-fourth of a grain (0.008 to 0.015 Gm.). The *solution of morphine sulphate* formerly official was made by dissolving one grain of morphine sulphate in one fluidounce of distilled water. Although the solution is more stable than that of any other of the morphine salts in use, it will in time deteriorate, either through the presence of microscopic plants or from other causes and, hence, it is not desirable to keep it on hand. This solution must not be confounded with *Magendie's solution*, which is *sixteen times as strong — i.e.*, sixteen grains in a fluidounce. This solution is often used hypodermically.

CODEINA. U. S. Codeine

[**Codein.**—Methylmorphine]

An alkaloid [$C_{17}H_{18}(CH_3)O_3N.H_2O$ = 317.28] obtained from opium or prepared from morphine by methylation.

Preparation—While codeine is obtained from opium directly after crystallization of the morphine from the aqueous extract, its largest source is by the methylation of morphine. Codeine is a substituted morphine in which one of the hydroxyls is replaced by methoxyl (OCH_3). Replacement can be made in many ways for which numerous patents have been issued as by the action of dimethyl sulphate on the alkaline earth combinations of morphine.

Codeine, which was isolated by Robiquet in 1832, is remarkable for being, with the exception of colchicine, the most soluble alkaloid in use, there being no necessity for salifying it. Its salts are frequently used and are even more soluble. In alcohol it has an $[a]_D$ −137°, or −111.5° in chloroform. It is usually seen in larger crystals than any other alkaloid.

Description and Physical Properties—Colorless, translucent crystals, or a white, crystalline powder. It is odorless, and is slightly efflorescent in warm air.

One Gm. of Codeine is soluble in 120 cc. of water, 2 cc. of alcohol, 0.5 cc. of chloroform, 18 cc. of ether, and in 13 cc. of benzene, at 25° C. One Gm. is soluble in 1.2 cc. of alcohol at 60° C.

Tests for Identity—When heated in an amount of water insufficient for complete solution, Codeine melts to oily drops, which crystallize on cooling.

Codeine rendered anhydrous by drying at 80° C. melts between 154° and 156° C.

A saturated, aqueous solution of Codeine is alkaline to litmus paper, and is lævorotatory.

Sulphuric acid, containing 0.005 Gm. of selenous acid in each cc., produces with Codeine a green color, which changes rapidly to blue, then slowly back to green.

Dissolve about 0.01 Gm. of Codeine in 5 cc. of sulphuric acid, add a drop of ferric chloride T.S., and warm: the solution becomes blue, changing to red on the addition of a drop of nitric acid.

Tests for Purity—When dried to constant weight at 80° C., Codeine loses not more than .6 per cent of its weight (*water*).

The ash from 0.5 Gm. is negligible.

About 0.01 Gm. of Codeine dissolves in 5 cc. of sulphuric acid (free from nitrous compounds) without producing other than a transient, pinkish tint (*readily carbonizable substances*).

Dissolve about 0.05 Gm. of potassium ferricyanide in 10 cc. of distilled water, add 1 drop of ferric chloride T.S. and 1 cc. of a neutral, or slightly acid, aqueous solution of Codeine (1 in 100) made with the aid of sulphuric acid: no blue color is produced at once (*morphine*).

Preserve in well-closed containers, protected from light.

N. F. Preparation—Elixir Terpini Hydratis et Codeinæ.

Uses—Codeine is a sedative, in doses of one-fourth to one grain (0.015 to 0.065 Gm.).

CODEINÆ PHOSPHAS. U.S. Codeine Phosphate

[Codein. Phos.]

Codeine Phosphate [$C_{17}H_{18}(CH_3)O_3N.H_3PO_4.2H_2O = 433.36$] contains not less than 67 per cent of anhydrous codeine [$C_{17}H_{18}(CH_3)O_3N = 299.27$].

Preparation—Codeine phosphate may be made by evaporating and crystallizing a solution of codeine in phosphoric acid.

Description and Physical Properties—Fine, white, needle-shaped crystals, or a white, crystalline powder. It is odorless. Codeine Phosphate readily loses water on exposure to air.

One Gm. of Codeine Phosphate is soluble in 2.3 cc. of water, 325 cc. of alcohol, 4500 cc. of chloroform, and in 1875 cc. of ether, at 25° C. One Gm. is soluble in 0.5 cc. of water at 80° C., and in 125 cc. of boiling alcohol.

Tests for Identity—An aqueous solution of Codeine Phosphate (1 in 20) is acid to litmus paper.

It responds to the identity tests with selenous acid, ferric chloride, and nitric acid under *Codeina*.

In an aqueous solution of Codeine Phosphate neutralized with ammonia water, silver nitrate T.S. produces a yellow precipitate, which is soluble in diluted nitric acid and in ammonia water.

Tests for Purity—Separate portions of 10 cc. each of an aqueous solution of Codeine Phosphate (1 in 100) show no turbidity at once on the addition of a few drops of barium chloride T.S. (*sulphate*), and no opalescence with a few drops of silver nitrate T.S. (*chloride*).

Codeine Phosphate complies with the test for *morphine* under *Codeina*.

Assay—Dissolve about 0.5 Gm. of Codeine Phosphate, accurately weighed, in 10 cc. of distilled water, in a separator, add 10 cc. of sodium hydroxide T.S., and extract the codeine by shaking with four successive portions of 15 cc., 10 cc., 10 cc., and 5 cc. of chloroform, or a sufficient quantity to complete the extraction. Shake the combined chloroform solutions with 5 cc. of distilled water, and completely separate the chloroform from the aqueous layer. Evaporate the chloroform almost to dryness on a water bath, dissolve the residue by warming with 15 cc. of tenth-normal sulphuric acid, heat the solution on the water bath until the odor of chloroform is no longer evolved, cool, dilute with about 10 cc. of distilled water, and titrate the excess of acid with tenth-normal sodium hydroxide, using 2 drops of methyl red T.S. as indicator. Each cc. of tenth-normal sulphuric acid corresponds to 0.02993 Gm. of anhydrous codeine ($C_{18}H_{21}O_3N$).

This assay is explained on page 1458.

Preserve in well-closed containers, protected from light.

Uses—Codeine phosphate is a valuable sedative, and is often preferred to other morphine salts. Dose, one-half grain (0.03 Gm.).

CODEINÆ SULPHAS. U.S. Codeine Sulphate

[Codein. Sulph.]

[$C_{17}H_{18}(CH_3)O_3N_2H_2SO_4.5H_2O = 786.69$].

Preparation—Codeine sulphate is made by crystallizing from a solution of codeine in diluted sulphuric acid.

Description and Physical Properties—Long, glistening, white, needle-shaped crystals or rhombic prisms, or a crystalline powder. It is odorless, and is efflorescent in the air.

One Gm. of Codeine Sulphate is soluble in 30 cc. of water and in 1280 cc. of alcohol, at 25° C. One Gm. is soluble in 6.5 cc. of water at 80° C. and in 440 cc. of alcohol at 60° C. It is insoluble in chloroform and in ether.

Tests for Identity—It responds to the identity tests with selenous acid, ferric chloride and nitric acid under *Codeina*.

Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate which is insoluble in hydrochloric acid.

Tests for Purity—When dried to constant weight at 100° C., Codeine Sulphate loses not more than 12 per cent of its weight (*water*).

The ash from 0.5 Gm. is negligible.

A solution of 0.5 Gm. of Codeine Sulphate in 15 cc. of distilled water requires not more than 0.3 cc. of fiftieth-normal sulphuric acid for neutralization, using one drop of methyl red T.S. as indicator.

Codeine Sulphate complies with the tests for *morphine* and *readily carbonizable substances* under *Codeina*.

Preserve in well-closed containers, protected from light.

Uses—Codeine sulphate is preferred by many practitioners to morphine sulphate. It is used as a sedative and narcotic. Dose, one-half grain (0.03 Gm.).

APOMORPHINÆ HYDROCHLORIDUM. U.S. **Apomorphine Hydrochloride**

[Apomorph. Hydrochl.—APOMORPHINE CHLORIDE]

The hydrochloride [$C_{17}H_{17}O_2NHCl.\frac{1}{2}H_2O = 312.71$] of an alkaloid prepared from morphine by the abstraction of one molecule of water.

Caution—Apomorphine Hydrochloride must be rejected if it at once imparts an emerald-green color to 100 parts of distilled water when shaken with it in a test tube.

Preparation—It may be made by heating morphine in a closed tube with a great excess of hydrochloric acid for two or three hours to the temperature of 140° to 150° C. The contents of the tube are then dissolved in water, an excess of sodium bicarbonate added, and the mixture extracted with chloroform or ether in which the alkaloid, unlike morphine, is readily soluble. It may be crystallized from the ether or chloroform solution by evaporation, in the absence of oxygen, or by shaking the solvent with a small amount of hydrochloric acid, when the apomorphine separates. The process is one of dehydration—the morphine parting with one molecule of water, thus:

$$\underset{\text{morphine}}{C_{17}H_{19}O_3N} = \underset{\text{apomorphine}}{C_{17}H_{17}O_2N} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties—Minute, white or grayish-white, glistening crystals, acquiring a greenish tint upon exposure to light and air. It is odorless.

One Gm. of Apomorphine Hydrochloride is soluble in 50 cc. of water and in 50 cc. of alcohol, at 25° C. One Gm. is soluble in 17 cc. of water at 80° C., and is very slightly soluble in chloroform and in ether.

Tests for Identity—The addition of a solution of sodium bicarbonate to an aqueous solution of the salt (1 in 100) produces a white, or pale greenish-white precipitate, which rapidly becomes green on exposure to air and when dissolved in ether, produces a violet color; in chloroform, a violet-blue color.

Apomorphine Hydrochloride dissolves in nitric acid, producing a dark purple solution.

Silver nitrate T.S. added to an aqueous solution of the salt produces a white precipitate, insoluble in nitric acid. This precipitate soon turns black by reduction to metallic silver, and is instantly reduced by the addition of ammonia water.

Tests for Purity—A saturated aqueous solution of Apomorphine Hydrochloride is neutral to litmus paper.

The ash from 0.2 Gm. is negligible.

Shake 0.1 Gm. of the salt with 5 cc. of ether: the latter acquires not more than a pale reddish color (*decomposition products*).

Preserve in small, dark amber-colored, well-stoppered vials, which have been previously rinsed with diluted hydrochloric acid and dried.

Uses—This remarkable compound is devoid of narcotic properties, but is expectorant in doses of one-sixtieth of a grain (0.001 Gm.), and a powerful emetic, hypodermically, in one-twelfth grain (0.005 Gm.) doses; it should be employed with caution to avoid excessive emesis.

ÆTHYLMORPHINÆ HYDROCHLORIDUM. U.S. **Ethylmorphine Hydrochloride**

[Æthylmorph. Hydrochl.—ETHYLMORPHINE CHLORIDE]
